The next plague was silver-fish, darting swiftly out of cupboards. These were more difficult to eradicate, but I seldom see one now. Spiders are, I am afraid, chronic, but then I rather like them; they seem to be part of the household. There are none of the fat Miss Muffet variety, but only those with a delicate air and legs like a film star's eyelashes. Last of all are the tortoiseshell butterflies. They hibernate high up on the dark beams of the staircase, and during the winter just hang there with folded wings, motionless as mummies; but with the first warmth of spring, they will awake and fly in and out of the windows bringing sunshine with the beauty of their wings into every room.

* * *

If you must dislocate your shoulder, the thing is to do it in the presence of a surgeon and an anæsthetist. It happened in this fashion to me, albeit late at night and in a country village. The patient was promptly laid on a bed in the local doctor's house and given intravenous pethidine, nothing stronger being available. Traction was exerted and I heard the anæsthetist remark "You'll have to put your foot in it, Charley," but this step proved unnecessary. With Kocher's method at the second shot there was an audible click and a sharp stab of pain, and the head of my humerus was back where it ought to be. The operation had been watched by august spectators—a principal medical officer from the Gold Coast Ministry of Health, and a member of the territory's medical disciplinary committee. Afterwards we all motored 30 miles to Korlebu, roused the surgeon's wife, and enjoyed five cups of her strongest tea.

* * *

The time has come when physicians should band together and defy the serious menace to their art which noisily fills our skies. It is virtually impossible now to use the stethoscope without the disturbing buzz of aircraft overhead. As one strains ecstatically for the rarest rub or the most musical of murmurs, one's senses are instantly shattered by the irreverent coughing and spluttering of these infernal engines. And the poignancy of the moment is the greater when one has just taken infinite pains and achieved infinite unpopularity in commandeering silence from the ceaseless chattering and sluice clatter that pervade all hospital wards.

The solution clearly does not lie with peaceful approaches. I have waited impatiently for a lull before running from patient to patient with chest-piece poised aloft. I have closed windows, I have bought thick rubber tubing, I have wound cotton-wool round my ear pieces, and I have shaken my fist in the air—all to no avail. No sooner do I reach for my stethoscope when a distinct drone revives my frustration. And as I stand by helpless while opening snaps and bronchial breathing go undetected, the drone becomes a crescendo of deafening vibrations, enough to discomfort Laennec in his place of rest.

The problem is urgent, for if a solution is not found soon, we shall have to throw away our stethoscopes and carry mechanical phonograms instead. Even so, we shall have to learn how to decipher the graphic squiggles of aeroplanes from those produced within our patients' chests.

PRESCRIBERS' NOTES

Where are the Snows?

Gold pencil, a tablet for writing, and then
They came as a Boon and a Blessing to men.
First the *Basis*, next *Adjuvant*, then the *Corrective*,
All inside the *Vehicle*—dog cart or brougham?
And, just to ensure they were doubly effective—
Well wrapped in dog Latin you couldn't see through 'em.
To those who were not getting rapidly well a glance
At your Prescription was good as a tonic.
Whereas nowadays, in this Age of Inelegance,
Ordered by telephone, tab. Supersonic
Is all you can hope for, except for the fact
That your doctor, like you, doesn't know how they act.

Concerning a further advance in the treatment of bucco-pharyngeal INFECTIONS

Dequadin Lozenges containing a new bactericidal and fungicidal substance are rapidly effective against all the common oral pathogens including those resistant to penicillin They do not contain any antibiotic or anaesthetic substance

Dequadin Lozenges are indicated in the treatment of Vincent's angina, tonsillitis, sore throat, stomatitis, pyorrhœa, pharyngitis, aphthous ulcers, thrush and glossitis

They can be used prophylactically in patients exposed to infection especially after tonsillectomy and dental extractions

By suppressing monilial growths, Dequadin Lozenges prevent the appearance of black tongue and oral thrush They are also rapidly effective in the treatment of oral thrush including that due to prolonged antibiotic therapy

DEQUADIN

LOZENGES

In tubes of 20 lozenges each containing
0·25 mg decamethylene-bis (4-aminoquinaldinium chloride)

conversion of linoleic to arachidonic acid Further, vitamin E, which is a powerful antioxidant and therefore protects E F A, is largely removed from low extraction flour *and what remains is destroyed by the "improvers."* The dietary intake of E F A and of unnatural fats in this and other countries during the past years is at present being examined by Miss Dorothy Hollingsworth, Dr J N Morris, and myself

EFFECTS OF E F A -DEFICIENCY

What are the consequences of deficiency of E F A in man? We can only surmise by arguing from the effects of such deficiency in lower animals First, deficiency would be likely to be at least five times commoner in males than in females Secondly, we might expect deposition of cholesterol since cholesterol esterified with unusually saturated or with unnatural fatty acids is probably disposed of less readily, diets high in saturated or unnatural fats or cholesterol or deficient in vitamin B_6 would enhance this Thirdly, E F A -deficient animals *are much more sensitive to noxious agents such as ultra*-violet light (mild doses of which we found to produce complete necrosis of an irradiated paw[14]), to X-irradiation[15] including probably its carcinogenic action, and perhaps to chemical carcinogens[16] In your columns Dr Nyrop has argued[17] for E F A -deficiency increasing the sensitivity, of males particularly, to a chemical carcinogen in tobacco smoke and so contributing to bronchial carcinoma, and in general I endorse his views Aortic atherosclerosis is unusually common in persons dying of bronchial carcinoma Are there not other forms of cancer the incidence of which might be similarly increased? For instance, deaths from leukæmia have *increased rapidly in the past two decades, are somewhat* commoner in males than in females, show peaks of incidence (particularly in the case of lymphatic) in persons under 5 and over 45 years, are commoner in the U S A and Denmark (a country with a highly developed medical service including radiography) than in England, are commoner in the rich than in the poor and (in the U S A) in white than in coloured persons, and are nine times more frequent amongst U S A radiologists than amongst other physicians[18] If the more highly civilised and wealthier peoples are becoming increasingly sensitive to the carcinogenic effects of X rays through deficiency of E F A, the above facts become explicable provided those young children who died of leukæmia were irradiated when their pregnant mothers had diagnostic radiography, a chemical carcinogen could hardly be responsible for their deaths But a chemical carcinogen in food, susceptibility to which has been increased by E F A -deficiency, might account for the susceptibility of males in particular to carcinoma of the stomach

EPITHELIUM AND NERVOUS SYSTEM

Seborrhœic eczema is a disease predominantly of males and appears to be increasing in incidence It resembles histologically the lesion found in E F A deficient rats, some cases are alleged to respond to vitamin B_6 by inunction but not by injection, and inunction of an antagonist of vitamin B_6 produces dermatitis[19], it is not impossible that this therapeutic effect is achieved by local conversion of linoleic to arachidonic acid, and that some cases of seborrhœic dermatitis are E F A deficiency Similarly the dermatitis that sometimes follows the local application of detergents may arise through these extracting E F A from the skin In lower animals, in which we have carefully studied the skin lesion of E F A deficiency and found a dramatic increase in permeability of th epidermis,[7,8] we believe there is a structural fau perhaps through failure of phospholipids containing E F A to polymerise and form the impermeable barrier i the stratum granulosum Phospholipids are rich in unsaturated fatty acids (though not so rich as cholesteryl esters), and although *we found them to be* normal in amount in the epidermis of E F A deficient rats they were abnormal in composition since the epidermal content of dienes and tetraenes had been enormously lowered In the E F A deficient dog[21] the iodine number of serum phospholipid fatty acids is lowered, as is that of serum cholesteryl ester fatty acids, whereas the iodine numbe of serum glyceride fatty acids is normal So, as in th case of esterified cholesterol, we have an abnormal typ of phospholipid being formed which may not only cause a structural defect in the skin which is responsible for th great increase in permeability but may also be outstandingly important for four reasons

First, the nervous system is rich in phospholipids containing polythenoid fatty acids, and these are found togethe with highly unsaturated cholesteryl esters in myelin, th presence of abnormal types of the compounds that are know to be important to it would be unlikely to leave functio undisturbed disseminated sclerosis is a disease of highl civilised countries being almost unknown in India an China, and other diseases in which the ectodermal neurogl is affected may be relevant, since serum E F A fall in acut infections it is not impossible that postinfective encephalomyelitis should be considered in this context, early mil dementia appears to be becoming commoner in males

Secondly, duodenal ulcers are increasing particularly i males, and in lower animals ulcers of the gut can be produce by feeding saturated fat

Thirdly, the mitochondrial membrane probably contain phospholipids, and derangement of this through deficiency o E F A might be responsible for the uncoupling of oxidativ phosphorylation found in such deficiency[22]

Fourthly, it is known that after a meal rich in fat th blood is more coagulable,[23] and recently it has been shown that the substance concerned is almost certainly phosphatidy ethanolamine

CORONARY THROMBOSIS

Phospholipids are increased in the serum of person with acute myocardial infarction, and if this compoun contained unusually saturated or abnormal fatty acids, would be expected to persist in serum for a longer tim *and might therefore be a factor in causing* thrombosis whether coronary or cerebral, in persons with athero sclerosis which I have concluded above may well b caused by cholesterol esterified with abnormal fatt acids Eighteen months ago, when we had obtained som evidence of the production of abnormal compounds called attention[25] to the correlation in this countr between the dietary intake of vegetable fat and death from coronary thrombosis "I believe the answer ma *be that the level of total dietary fat is related to* atheroma but that the level of dietary *vegetable* fat is related t clotting upon atheromatous plaques, and hence t coronary thrombosis" In general it is the vegetable fat that are hardened and may give rise to abnormal phospholipids But at that time we had been fortunate in having Dr Ancel Keys recently to work with us and I had bee impressed in general with his belief that total dietar fat, of whatever kind, was related to atheroma thoug we differed about its relation to coronary thrombosis an about Eskimos who have high dietary fat and allegedl little atheroma Since then I have come to realise tha Keys's hypothesis is not correct what matters

Inflammation and Cortisone

Interest in inflammation is as old as medicine Celsus, who described its four cardinal signs (Galen added the fifth), and all physicians for centuries later considered inflammation as a disease, and their treatment was guided by this idea John Hunter was probably the first who saw inflammation as a defence against a variety of injuries The first half of the 19th century brought a number of accurate observations and experiments, among which those of Addison and of Waller[1] were prominent, and they culminated in the classical work of Cohnheim[2] The descriptions by him and his predecessors of tissue changes in inflammation were based on in-vivo microscopic observations of transparent tissues, such as tongue, web, and mesentery of the frog The main vascular events were firmly established by Cohnheim, and Metchnikoff's work on phagocytosis[3] brought further progress In the years that followed there was much controversy between those who, like Metchnikoff, believed in a central cellular defence mechanism and those who laid more stress on humoral factors, Lewis's[4] brilliant work on the triple response to mechanical injury and the immediate release at the site of injury of a histamine-like substance, convinced many physiologists that histamine was responsible for the vascular changes of inflammation Rous and Gilding[5] however, showed that there were differences between the vasodilatation produced by scratching and that produced by histamine For some time interest also centred on hyaluronidase This enzyme, which hydrolyses hyaluronic acid, a constituent of connective tissues, is produced by some bacteria and was believed to be important in breaking down the host's local defences, but experiments showed that there was no relation between the virulence of bacteria and their ability to form hyaluronidase[6,7] Meanwhile, another question under investigation was whether the accumulation of inflammatory exudate was the result of increased venous pressure or of increased capillary permeability Dyes, such as trypan blue, Evans blue, or isamine blue, which, when injected intravenously become protein-bound and normally do not pass out of the circulation, were much used in these inquiries Ramsdell[8] who introduced this technique, held that accumulation of dye in an inflamed area indicated endothelial capillary damage, and this view is now generally accepted It was soon found that histamine was not the only substance which increased capillary permeability, and Menkin's work[9] of the past two decades drew attention to other substances found in inflammatory exudates which cause emigration of leucocytes and increased capillary permeability Menkin isolated from inflammatory exudates a peptide with these actions, which he called leucotaxine Spector,[10] working in Cameron's department, found that in rats enzymatic digests of various proteins caused (1) increased capillary permeability, (2) swelling of endothelium and (3) emigration of leucocytes Only peptides of 8–14 amino acid units produced all three effects, and so did the crystalline pancreatic-trypsin inhibitor, which has a molecular weight of 6000 Of great interest and possibly related to the mechanism of inflammation is a finding reported recently by Jepson et al[11] They discovered a pain-producing substance which is formed in human plasma merely by contact with glass This substance is very similar to or identical with bradykinin, a peptide generated from bovine plasma or α_2-globulin and from human plasma by the action of snake venom or trypsin The significance of these findings in explaining the mechanism of inflammation lies in the possibility that mere contact of plasma with a foreign body or damaged endothelium, or with any tissue other than normal endothelium, may produce a bradykinin-like peptide

Interest in the mechanism of inflammation was renewed when it became clear that there was a close relation between cortisone and corticotrophin (A C T H) on the one hand and the course of infections on the other Reviewing this subject in 1952 Thomas[12] was able to collect 115 published reports of animal experiments and observations on human beings Among the earliest workers, Finland et al[13] described dramatic improvement in pneumonia and Smadel et al[14] and Woodward et al[15] recorded similar benefit in typhoid fever, but they found bacteræmia at the same time as clinical improvement The experimental and clinical work which followed showed clearly that cortisone made many infections worse Although inhibition of antibody formation was often but not invariably reported, most workers nowadays lay more stress on changes in *non-specific general* and particularly local defence mechanisms Investigations of the Shwartzman phenomenon and observations of the course of inflammation in the living animal have been particularly helpful Thomas et al[16,17] found that cortisone-treated rabbits showed no local reaction twelve hours after an intradermal injection of toxin while in the control animals erythema and œdema developed After eighteen to twenty hours there was still no erythema or œdema in the treated animals, but many small petechiæ appeared In other experiments, when cortisone (25 mg daily) was given for four days, the intravenous injection on the third day of meningococcal toxin was followed within

Although we still use large quantities of aspirin in this practice, when gastric irritation or sensitivity appear, with their sinister implications, panadol becomes the drug of choice, and having used it now for two years we find it a satisfactory analgesic which is tolerated better than tab codein co or aspirin, side effects being negligible

DOMICILIARY CONSULTATION IN PSYCHIATRIC PRACTICE

SIR,—I was interested in Dr Skottowe's letter (Jan 14) and in Dr Hopkins's reply

If the universal overcrowding of mental hospitals is to be alleviated, some calculated risks must be taken in returning relatively stabilised schizophrenics to the outside world But this will be of little use until the community has been trained to accept people with some degree of emotional handicap, as they now accept people with some degree of physical handicap

In this country the Canadian Mental Health Association is doing a great deal to educate the public along these lines

The association engages speakers, holds discussions, and encourages visits to the Provincial mental hospitals and clinics. A recent departure is the setting up, by the association of a social club for patients in Regina It is used by patients living in the city who have been either in one of the mental hospitals or in the Munroe Wing (a small psychiatric unit attached to the Regina General Hospital) Although the idea of the social club for discharged patients is far from new, this is, as far as I know, the first example of such a club being run by a voluntary organisation This scheme receives considerable support and encouragement from the doctors working in the Provincial psychiatric service, but no doctor actually attends the centre, as it is felt that it would be undesirable for those using it to feel that this was merely an extension of the institution which they have just left The centre is in the charge of a psychiatric social worker, who carries out counselling and if necessary, suggests to a patient that he should again seek medical advice

Munroe Wing,
Regina General Hospital

STAPHYLOCOCCAL INFECTION AFTER CARDIAC SURGERY

SIR,—Reading your annotation of Feb 11, I was struck by the fact that there is no mention of oral sepsis Fleming and Seal[1] make only an indirect reference to dental *extractions* as an ætiological factor in streptococcal bacterial endocarditis, the state of the mouth not being mentioned in the cases described Again in the full survey of wound infection in a thoracic surgery unit by Blowes et al[2] the gums are not considered as a portal of entry

Oral sepsis is no longer regarded as the cause of all the ills to which the body is heir, but it is generally agreed to be an important factor in bacterial endocarditis The pioneer work of Okell and Elliott[3] and of Round et al[4] provides experimental evidence of bacteræmia occurring *without operative interference* which has been confirmed but never refuted Most patients with heart lesions and many patients awaiting a thoracic operation have periodontal disease often in an advanced form The organisms in the gum pockets of these patients may pass into the blood through the pumping action of chewing or grinding The mouth flora will include *Streptococcus viridans* as well as staphylococci both coagulase positive and negative, which are likely to bear some relation to the bacterial flora of the ward after some time in hospital If a dental extraction can lead to infection of a diseased endocardium, surely dental bacteræmia can occasionally infect a valve damaged by tearing, the cardiac suture line or the dead spaces which may occur in thoracic surgery Fleming and Seal presume that the organisms gain ent at the time of operation A study of the case histories do not justify this presumption, normal convalescence bei apparently abruptly disturbed It is more reasonable postulate that, the penicillin cover for the operation ha ceased, severe bacteræmia develops when the patient be to masticate more vigorously, the mouth being relative unhygienic, as it is, despite nursing care, after all ma operations

There are ample possibilities of infection witho implying that all are due to oral sepsis My purpo is to draw attention to the mouth as a portal of entr A great effort is being made to provide full dental trea ment for patients in all hospitals, and it is importa to appreciate that the dental service can do more tha just ward off toothache Efficient preoperative dent prophylaxis—that is, scaling and polishing, wheth by dental surgeon or dental hygienist—can be a important factor in the prevention of postoperativ complications

London W 1 B W FICKLING

BILLROTH-I AND POLYA OPERATIONS

SIR,—I have read with interest the comments o Professor Goligher and his colleagues (Feb 4) on th veteran contest of Billroth-I versus Polya operation

I am sure they are right that if there is trouble from leaku anastomoses, at least one way out of it is to compromise wi living, undernourished, dumping, bile vomiters, in the good proportions which a Polya procedure will provide, rather tha to encourage mortality from leakage Even then it woul appear that the duodenal closure must be carefully done o leaks abound One wonders whether, when there are instanc of separation of the anterior part of the anastomosis wi leakage into the peritoneal cavity leading to disaster, the may not be an equal or greater number of separations on th lesser curve, or at the more difficult posterior part of th anastomosis (comparable to the formation of any penetratin posterior duodenal ulcer) with sealing and no leakage, but resulting large gap between mucosal surfaces leading t subsequent ulceration

I agree also that " it was surprising to find that the majorit [of recurrent ulcers] were on the lesser curve of the stomach More than 100 of my own Billroth I series of two third resec tions have been operated on for over three years, like the own series, but with, so far, no recurrent ulceration on th lesser curve The recurrence rate after the standard Billroth operation for duodenal ulcer does appear to be, in mo surgeons' hands, on the high side (my own being 6%), bu the 15% described by Goligher et al seems exceptionally hig Capper and Welbourn[1] have done much to show that the ra of recurrence depends chiefly on the amount of stomac resected, and with the extra gap to be filled followin resection of a duodenal ulcer and the necessary accompanyin length of duodenum, there is a tendency to skimp the resectio to avoid tension with resulting leakage at the anastomosi even though with full mobilisation really high resection feasible It is always difficult when several surgeons ar involved in a series to know exactly how much stomach eac has resected In my personal series I have found that m assistant at times recorded a resection less high than I hav credited myself

Radiographic examination in my own cases has show distortions of the lesser curve, but these have all been th "puckering and distortions" which Goligher et al mention and twice I have even sought these lesser curve "ulcers" at operation by direct inspection of the interior of the stomach with disillusioning results Increasing experience makes m feel that with the very best of radiologists the interpretatio of the shadows of barium in the stomach and duodenum ar often less accurate than the interpretation of the telescop appearance of the planet Mars It may be possible that som of the lesser-curve recurrences were really original concomitan gastric ulcers which possibly were not sought at the primar operation for it appears that as Goligher et al did no inspect directly for the "ulcer" at the second operation they may not have done so at the first operation either further analysis by Capper and Welbourn[2] of the results o many partial gastrectomies for ulcer by numerous surgeon in these subjects This is, I think, less likely to happen in America"

In our own medical schools, though "fear of examination failure with resulting withdrawal of financial support is very great,' much remains still of that carefree attitude to life for which the British medical student has always been famed By contrast, the American student is a very serious person and works much harder "He has had plenty of fun at college and is now ready and able to take things seriously" His devotion to his studies does not seem to arise either from fear of examinations or merely from awareness of competition with his colleagues "In the schools I have visited perhaps there is still some apprehension about anatomy and other preclinical subjects, but I think it is mild and probably will soon be as negligible as that felt for final examinations" Dr ELLIS is impressed by the American student's readiness to speak his own mind "to any teacher at any time,' his critical attitude, and the uninhibited manner and clarity with which he expresses himself

The main reason why the American student works hard is that he is impelled to do so by "that most powerful incentive to work—interest in it The interest that the average student in any faculty in any university takes in his work must be in large measure merely a reflection of the interest his teachers take in him" and Dr ELLIS speaks enthusiastically of the interest taken in the individual student by the majority of teachers in American medical schools No doubt there are still many places where "teaching is regarded as synonymous with talking, where, nameless in a crowd, the student must fall back on his books, only to impair his education, eyesight, and sanity in a hopeless fight to achieve "complete coverage" But the present trend is away from this In many medical schools "the process of teaching is regarded as imparting inspiration and guidance to learning, with the imparting of factual knowledge only so far as is required by the former where such an attitude of mind exists on the part of the teachers there is little need to look further for incentive to hard work on the part of the student and the curriculum is by comparison almost unimportant"

All systems, however, are liable to the defects of their qualities Dr ELLIS feels that some American medical schools, though undoubtedly right in putting the chief emphasis on education, do not give their students enough technical training "Medical education, while being subject to the general principles of all education, is also subject to the peculiar needs of training for work in the profession of medicine" facility in the technique of clinical methods and practical skill in obtaining information from the patient is vitally important, and Dr ELLIS suspects that American students are weak in this respect He attributes this weakness first to a lack of sound introduction to clinical methods at a time when their whole attention can be focused on it, and secondly to the absence of constant and prolonged practice of it

> "It is not that American medical students take poor histories and make poor examinations, it is that they appear to suffer from a lack of balance between their knowledge of medicine and their knowledge of diseased people This second knowledge can surely only be acquired by the steady application of clinical methods (with increasing skill) to patients This constitutes experience, and when there is lack of balance between knowledge and experience there is an increased feeling of insecurity in dealing with patients"

This feeling of insecurity might explain why the final-year American student is sometimes unable to make use of his own knowledge—why he is so often overcome by a sense of inadequacy when faced with the problem of the "whole man" rather than a particular disease Dr ELLIS points out that, though postgraduate training could do much to remedy this defect, it is still outside the control of the American medical schools It is a great thing that the new graduate should leave his school with the ability to learn and a will to go on learning, but he will be handicapped until he acquires clinical skill to match his knowledge

Dr ELLIS would probably agree with us that, if American teachers tend to neglect technical training in favour of basic education, we in this country have hardly yet begun to realise how far we are guilty of the opposite error To those who regard American medicine as excelling mainly in the use of techniques, and to those who think of American medical schools as huge and impersonal, it will come as a surprise to hear how deeply American teachers are concerned with fundamental principles and how much thought time, and trouble they devote to their students as individuals

Protection and Liberty

LENDING money to friends is said to be a sure way of losing their friendship, and the same applies to helping races or individuals whom we may think need our care and protection most of the horrors of history have sprung directly from well-meaning efforts to change people against their will The obligation to try to help certain types of people, even against their wishes, is inherent in our social structure, but those who spend their lives protecting their neighbours from themselves need expect little thanks from the objects of their solicitude and must be prepared for the criticism of those who prefer the touchline to the centre of the field

Assuming that we know what is best for our neighbour, we must be prepared to answer two questions on our stewardship in what circumstances can we force him to follow our advice, if not our example, and at what point should we retire and leave him to look after himself? As a nation we have long been the self-appointed protectors of many races, and today our problem is when and how to withdraw without undoing the good work we have done We fear to hand over our garden while the serpent is at large But we should not forget that most peoples prefer their own misgovernment to good government by others, and think that they can deal with snakes as well as anyone else

At home we have to face the same problems in our dealings with some of our fellow citizens In our society everyone is legally under care until he comes of age, but his emancipation is normally only a matter of time Some 3 per 1000 of the population, however, are liable to qualify for compulsory care because they are judged to be mentally defective, and though for low-grade defectives the need for care arch, is rarely found The true congenital flat foot is easily diagnosed very early in life and here the problem of treatment is entirely different

It is my experience that unless we distinguish most carefully the deformity which is present and give it its correct descriptive title, we shall be tempted to give *treatment which is incorrect, inadequate, and too* complex

Manchester, 3 W SAYLE-CREER

CHRONIC PAROXYSMAL HYPOGLYCÆMIA

SIR,—I should like to thank Mr Altounyan for reporting (Feb 11) the interesting history of a case of hypoglycæmia due to an islet-cell tumour of the pancreas, with symptoms for fifteen years prior to operation It is a pity that a histological report was not available at the time of writing, but presumably the case was one of benign adenoma

I should, however, like to take issue with the terminology used in the title of the paper

The term ' chronic paroxysmal hypoglycæmia " is non descript, cases of this sort should be regarded as examples of " hyperinsulinism," as we have recently pointed out[1] This will avoid unnecessary terms, and enable similar cases to be more easily categorised

Further, Mr Altounyan uses the subtitle " Whipple's syndrome " Whipple's disease (intestinal lipodystrophy) was described by *G H* Whipple in 1907[2] Whipple's triad of criteria for the diagnosis of hyperinsulinism were propounded by *A O* Whipple in 1935[3] If an eponym is to be employed, preference could be given to Wilder, who described the first case in 1927[4], Harris, who first used the term in 1924[5], or Campbell, who did early work on the symptoms of hypoglycæmia in 1922,[6] and was associated with the first successfully operated case in 1929[7] With such a large field, it is I suggest, preferable to avoid an eponym Most workers are content with the term hyperinsulinism

Diabetic Department,
King's College Hospital,
London, S E 5 H D BREIDAHL

MYXOMATOSIS

SIR,—Dr Brailsford (Jan 14) states " The Ministry of Agriculture has unsuccessfully used extermination measures for fifty years, at very great cost in value of herds of cattle and flocks of poultry, to get rid of swine fever, foot-and-mouth disease, and fowl-pest, but it has learnt little or nothing of cure of these conditions though smallpox, cholera, typhoid, plague, and tuberculosis have largely been eradicated without the aid of unprofitable destruction of this type "

The veterinary profession, when dealing with the food producing animals, has two prime duties (1) to stamp out any source of infection which may be transmitted to the human population, and (2) to increase the productivity of these animals in order that the nation's larder may be preserved There are two methods at hand for prevention of disease (*a*) vaccination, and (*b*) slaughter and the rigid isolation of the affected area Most bacterial diseases are controlled by vaccination, but most virus diseases have to be controlled by slaughter because of the peculiar characteristics of many viruses existing in several strains and provoking only a short-lived immunity It is true that we have learned little or nothing of the cure of our virus diseases, but then, has anyone ? We cannot cure foot and mouth disease, swine fever, or fowl pest I am sure Dr Brailsford would agree that there is similarly no cure for the common cold, influenza, or poliomyelitis We can and do protect against swine fever by vaccination (there is no official slaughter policy against this disease) and we have eliminated foot and mouth disease as an enzoötic by slaughter We have completely eliminated such diseases as glanders, cattle plague and rabies by slaughter, and are now eliminating tuberculosis from our cattle population

It is to be hoped that members of the veterinary profession will never tolerate the slaughter of animals when control by vaccination is an alternative

GONADAL DYSGENESIS AND TESTICULAR TUMOURS

SIR,—The recent finding that nuclear sex can be easily determined by the examination of vaginal smears[1-3] has enabled us to investigate systematically cases of primary amenorrhœa In the course of this work we have come across a patient with a quite unusual clinical picture[4], to our surprise the cell nuclei in the vaginal smear were chromatin negative

A 27 year old single woman consulted us on account of hirsutism She had gross features and pronounced virilism Investigation revealed a calcareous tumour in the minor pelvis, adrenal cortical dysfunction, and increased urinary excretion of 17-ketosteroids At laparotomy, a solid, fist size tumour at the site of the left gonad was removed together with the uterus, fallopian tubes, and right gonad Histopathological examination disclosed that this gonad was rudimentary (" streak ovary "), and the tumour was a dysgerminoma Postoperatively intensive X ray treatment of the pelvis was started, and the patient is still well after two years Ethanol extract of half the tumour mass contained no 17 ketosteroids and but little œstrogenic substance After irradiation, and possibly as a consequence thereof, the 17-ketosteroid excretion level diminished

Dysgerminoma is known to be endocrinologically inactive We therefore assume that in this patient the virilism was caused by dysfunction of the adrenal cortex similar to that in the adrenogenital syndrome The fractionated 17-ketosteroid pattern was in full accordance with this assumption

This case thus presents a striking syndrome, consisting in the combination of (1) gonadal dysgenesis, proved by the rudimentary gonad and the male nuclear sex, (2) dysgerminoma, and (3) adrenal dysfunction

The evaluation of recent developments in embryological endocrinology, and study of other cases recently reported, soon convinced us that this peculiar syndrome was not to be regarded as a purely fortuitous coincidence Patients with so called " ovarian " agenesis have been shown to be mostly male *It is assumed* that in these patients the male gonad, its anlage, or an essential component, must have been destroyed by some obscure early intra-uterine lesion, resulting in completely female sexual development Although dysgerminoma occurs mostly in normal women, attention has since long been focused on its association with gonadal anomaly and hypoplasia Novak[5] points out that " dysgerminoma is the most common tumour of pseudohermaphrodites, as it is of males with cryptorchidism " Cryptorchidism also represents a distinct gonadal aberration, occurring in males Concerning the accompanying adrenal dysfunction Novak[6] and Ber[7] have described cases with hirsutism and virilism, entirely comparable to ours, and dysgerminoma itself is generally believed not to be the source of androgens It is tempting to assume that the early *intra uterine injury may damage, not only* the sole gonadal anlage, but more or less the entire urogenital ridge This could explain the most varied combined

region need vaccination. The board suggests that hospital management committees should appoint some one to "persuade the staff to be vaccinated", and there can be little doubt that suitable propaganda within the hospitals would increase very considerably the number of those protected. It was also suggested that the practice in many hospitals before 1948 of making vaccination a condition of employment might be reintroduced.

The matter is closely linked with infant vaccination: the rate in this country is now only 34%. Primary vaccination in adults carries a greater risk of complications than in infants, and there is some doubt about the wisdom of vaccinating large numbers of adults, unless there is immediate danger. But nurses and particularly nurses in infectious diseases hospitals, run special risks, and we share the misgiving of the Sheffield board at their vulnerability. The annual reports of the Ministry of Health have repeatedly drawn attention to this serious position, and the Ministry has just produced a revised version of the memorandum[12] on smallpox vaccination. Yet apparently not enough has been said, for clearly not enough has been done. Air journeys from smallpox-endemic areas take less time than the incubation period of the disease. There have been 23 importations of variola major in the past ten years, and there will undoubtedly be more; it is very probable, also, that unrecognised cases will once again enter hospital. *All* the staff *must* be protected.

AMŒBÆ PRESENT?

EVERY morning a long file of black soldiers in white pyjamas used to approach the laboratory down the avenue of palm-trees. Each bore before him a bedpan decently shrouded in a "cloth, distinctive". They were the inmates of the dysentery ward bearing their daily offerings. After a few weeks it was easy to demonstrate without hesitation the amœbæ of all sorts, both ambulant and encysted. But the mind goes dim as quickly as the eye, and most pathologists who thought that they "knew the amœbæ" would admit that when they see a suspicious object under the microscope today their hand reaches for the textbook and its pictures. Though these will refresh the memory, for the student of tropical medicine no book can replace the teaching of the master at the bench—and weeks, months, and years of experience. The tricks of the trade are many and hard to put on paper. Some rely for detection upon the flash of the refractile amœba as the microscope is brought into focus; others on a background of weak eosin to distinguish protozoon from trash. Arguments on the proper strength of the iodine solution to display nuclei have never stopped. Some put great faith in concentrating the cysts by changing the specific gravity of the substrate; others say that the examination of up to *ten* natural specimens yields more profitable results. When the masters disagree the pupil may do worse than to follow undeviatingly the methods of one of them until he knows enough to disagree. Into a few pages of the newly founded *Central African Journal of Medicine*[13] Sir Philip Manson-Bahr has distilled a life time's knowledge of amœbiasis. Here are the wisdom of experience and methods proved by time. Many a solitary doctor in the further parts of the world will, having read this article, turn back to the bench with renewed enthusiasm; but the author still would be the first to admit that without a microscope and ample material the student will learn little by reading alone. It is probable that this difference between experience and booklearning explains the wide range of estimates of the occurrence of cysts of *Entamœba histolytica* in this country. The practised eye in the hospital for tropical diseases sees things overlooked in most laboratories. It is time for a clear answer to the question, "How many 'normal' people in this country are passing cysts?" and, as a corollary, "Why do we see so few patients with the classical disease?"

PROSPECTS FOR LABORATORY TECHNICIANS

DURING the past twenty years laboratory technicians have become more numerous and more necessary, more skilled and more responsible, and they are now essential members of the team headed by the pathologist. Similar changes have taken place elsewhere, in pharmaceutical manufacturing houses and in Government departments, and many of the young men who would once have taken an apprenticeship now stay at school a year or two longer and then enter some laboratory. If the National Health Service is to get its proper share of the best men for its laboratories, the financial prospects it offers should broadly resemble those in industry and in comparable grades of the Scientific Civil Service. It may be useful to compare the salaries offered to men of comparable education and skill for jobs of similar responsibility, in the National Health Service (under the new grading and salary structure recently announced[1]), in a large pharmaceutical manufacturing firm, and in a large institution of the Scientific Civil Service.

Entrants, who are expected to have the General Certificate of Education with passes at ordinary level in four subjects, including English, mathematics, and a science, have salaries nearly £100 per annum less in the National Health Service than in industry or in the Civil Service; the difference falls to £75 a year by the age of 21, but it is not until at least five years after entry, when the associate examination of the Institute of Medical Laboratory Technology has been passed, that the scales coincide. In the National Health Service there are two marks of efficiency, the intermediate and final examinations of the Institute of Medical Laboratory Technology, which do not exist in the Civil Service grade of scientific assistant, though in industry the supervisor's assessment of merit, on which salary increases depend, probably plays an equivalent part.

The selection of supervisory technicians varies greatly. In the National Health Service they are selected from those who have passed the final examination of the I.M.L.T. in a second branch, some six years or more after entering the laboratory; and to gain this advancement (and a further promotion to chief technician five or ten years later) the technician *may* have to move his home. In industry promotion is by selection, and if a move is necessary the employers often give financial help. In both cases, the senior or supervisory technician can expect a maximum salary of between £800 and £1000. The Scientific Civil Service selects its supervisory technicians, who are called experimental officers, by open competition at ages between 18 and 31, from those who passed either the G.C.E. at advanced level in two mathematical *or* scientific subjects, the intermediate B.SC., or the Higher National Certificate, or who hold a pass degree—or who have attained equivalent standards, according to age at entry. Scientific assistants, the junior grade, are considered only when they are recommended by their present department or have attained the requisite educational standards. Successful candidates can rely on attaining a gross salary of £935 in thirteen years, and some may enjoy accelerated promotion. A very few may be promoted to higher grades whose duties have no equivalent in the hospital service.

The range of salaries offered to technicians in the National Health Service under the new agreement is thus roughly comparable with those elsewhere; but there is arch, is rarely found The true congenital flat foot is easily diagnosed very early in life, and here the problem of treatment is entirely different

It is my experience that unless we distinguish most carefully the deformity which is present and give it its correct descriptive title, we shall be tempted to give treatment which is incorrect, inadequate, and too complex

Manchester, 3 W SAYLE-CREER

CHRONIC PAROXYSMAL HYPOGLYCÆMIA

SIR,—I should like to thank Mr Altounyan for reporting (Feb 11) the interesting history of a case of hypoglycæmia due to an islet cell tumour of the pancreas, with symptoms for fifteen years prior to operation It is a pity that a histological report was not available at the time of writing, but presumably the case was one of benign adenoma

I should, however, like to take issue with the terminology used in the title of the paper

The term "chronic paroxysmal hypoglycæmia" is nondescript, cases of this sort should be regarded as examples of "hyperinsulinism," as we have recently pointed out[1] This will avoid unnecessary terms, and enable similar cases to be more easily categorised

Further, Mr Altounyan uses the subtitle "Whipple's syndrome" Whipple's disease (intestinal lipodystrophy) was described by *G H* Whipple in 1907[2] Whipple's triad of criteria for the diagnosis of hyperinsulinism were propounded by *A O* Whipple in 1935[3] If an eponym is to be employed, preference could be given to Wilder, who described the first case in 1927[4], Harris, who first used the term in 1924[5], or Campbell, who did early work on the symptoms of hypoglycæmia in 1922,[6] and was associated with the first successfully operated case in 1929[7] With such a large field, it is I suggest, preferable to avoid an eponym Most workers are content with the term hyperinsulinism

The Widdicombe File

XXXII THE BASE DEGREES BY WHICH WE RISE

DEAR BARBARA,

Thank you for sending me such a helpful account of the Faculty of Omphaloscopists and their exams No, I'm not proposing to chuck pathology and turn omphaloscopist at my time of life It is merely that I am trying to make up my mind about some problems of organisation and exam structure that are worrying pathologists these days and your Faculty is an accepted model of efficiency in these matters and it seemed worth finding out more about it Perhaps you'd like to know a little about us in return (I ought by the way to say that the worried pathologists include several more or less official committees, but I know what the committees are up to only at very much umpteenth hand, and speak only as the most private of private individuals)

You might ask *then* what sort of representative organisation we pathologists have, what sort of regulations there are as to admission to our branch of the profession, and what examinations there are which the aspiring pathologist must take And I would answer you, with only a little exaggeration, as to the first, none, *as to the second, none, and as to the third*, none again This will not be believed in Venice ? Yet it is true

Unlike nearly every other specialty, including yours, pathology has no exam structure If the recent graduate wants *to* become an omphaloscopist, he knows he must pass *as* soon as he can his D OMPH Later, if he aspires high, he can go for his F F OMPH R C S The array of similar diplomas—D M R, D A, D C H, D P H, D OPHTH D OBST R C O G, D P M, and so on—with a variety of higher degrees to match, speaks for the generality and popularity of the system Failure to acquire the correct diploma is the clearest of red lights against persevering in any of these *specialties* *But not so the young pathologist* The D C P and D PATH exist, but hardly do more than exist so far as this country is concerned—I'll come to them later—and higher degrees are by no means necessary at any stage There are several distinguished *professors of the subject* who take a simple pleasure in flaunting their bare M B Consultant jobs admittedly go nowadays usually to people with some sort of higher degree, but the higher degree may be one of several *most* diverse sorts and there is no agreement as to which, if any, is most worth having

Our absence of exams is matched by our absence of professional organisation (the two things of course nearly always go *together—admission to the cult* by ordeal is as characteristic of professional bodies as of primitive souls) We have the Pathological Society, in professional standing as high as any of its kind in the world Like all successful societies, it is getting too big like all *successful fields* of science, pathology is getting too big for one society, and *only* the last ditch determination of a few diehard general pathologists to understand every paper delivered, or ask questions until they do, preserves its meetings from unintelligibility By and large, however, it is still the respected fulcrum of pathology as a science in this country But with the political aspects of pathology it will have nothing to do Like Gallio, it says

> ' that is a question of wages and names
> And I know the strife it brings
> I will not pass upon any of your claims
> I care for none of these things "

Firmly and *loftily*, it insists it is a Scientific Society, unconcerned with the affairs of the market place Pig-headed, perhaps, but also longheaded When scientific societies start playing politics, usually a rush of splinter groups starts, and soon it is one of the splinter groups that is the real scientific society, and the parent body is a mere *talking* figurehead But, as a result of the political nihilism of the Pathological Society, its main splinter party, instead of being a ginger group of young pathologists, is ambitious of turning into a Representative Body The Association of Clinical Pathologists has remained a second eleven scientifically, but it is willing, unlike its senior partner, to recognise that pathology is not only a science but a way of earning a living (Do not think one must therefore despise the A C P Our two societies represent the mundane and the lunar, the *yin* and the *yang*, of a scientist's existence today he must give his work, and he must be paid for his work) Willing though it may be to organise us, it is not yet very successful it is handicapped not so much by being young and brash and *too openly technological* in its approach, but because many pathologists—including many of the older and most influential—just frankly do not want to be organised and those few who enthusiastically believe in organisation have the *most diverse views* as to how it should be done

This agnosticism about organisation, this rottenness at the core (as you, Barbara, with your well drilled omphaloscopists, must think it), has many roots For one thing, we include, to our great benefit, the best array of out and-out individualists—not to say eccentrics—to be found in medicine For another, organisation entails an admission that ours is a specialty like any *other, whereas all true pathologists* know in their hearts that pathology is not a specialty in medicine, but *the* basic science of medicine (To claim that we are *not* merely consultants, but consultants' consultants, smacks a little of pride) It is to be noted that the urge to organise comes mostly from the clinical pathologists, to whom avowedly pathology is just another ancillary diagnostic service for the hospital

Various sorts of organisation have been suggested A College of our own ?—we can't afford one A Faculty ?—but of what ? The Academy of Medicine, uniting the four Colleges, seems still a pipe dream We could hardly become a faculty of the Obstetricians or the G P 's There remain the Physicians and *the Surgeons* The R C P won't have us (or anyone their constitution remains and will remain Linacrean) A pity this there's much to be said for it on both sides but the College remains as narrow in some of its ideas as the preposterous finger's breadth off Trafalgar Square to which it clings so sentimentally It is perhaps overstating the case to apply to them Eliot's

> " *Do not let me hear*
> Of the wisdom of old men, but rather of their folly,
> their fear of possession,
> Of belonging to another, or to others "

But they seem sometimes, whatever their merits as *individuals*, as a College to be a little over preciously concerned with their integrity The case is otherwise with the R C S The Surgeons are broader-*minded* (perhaps just richer) *than* the Physicians, and would probably have us But *timeo Danaos* there is the *old* Spanish proverb to be remembered " Take heed of an ox before, a mule behind, and a College *of* Surgeons on all sides " Moreover, while it is legitimate for Anaesthetists and Radiologists and Omphaloscopists to fall in behind the surgeon's antique *drum*, it would be more than a little infra dig for *the* basic science *of* medicine Shades of papa Virchow !

Exams *are at* present the crux of the matter The young man entering pathology, needing a motive (whether he realises it or not) to preserve in him his studently habit of work, sees with mixed feelings his contemporaries systemic lupus erythematosus, or in a symptomatic and self-limited fashion as in certain cases of drug allergy, among which the lupus-like syndrome arising in some hydralazine hyperreactors is notable[18] One is led to wonder whether a similar chain of events might take place also in selected "hyperergic" (joint pains!) cases of viral hepatitis but, to prove this, further investigations are needed In our own control material which has been collected for more than five years, nothing more than occasional nucleophagocytosis has been observed whether in chronic or acute hepatitis, both by the anticoagulant and defibrinated techniques

Genova Italy

ALBERTO M MARMONT

VANISHING LUNGS

SIR,—Your editorial,[19] which gave a very concise yet informative account of this fascinating subject, referred to a recent article[20] by one of us May we indicate some aspects which have so far not been adequately considered?

You emphasised the practical problem of abnormal air-spaces appearing in areas of tuberculous processes healed under the influence of chemotherapy These have raised the difficult question of "open" healing of tuberculous cavities, which in turn has led to the current dispute over resection versus *conservative management of such residual lesions* Here the work of Medlar[21] must be carefully considered

The concept of "open" healing of tuberculous cavities has not been borne out in Medlar's extensive and very careful histological studies In true tuberculous cavities Medlar could find no evidence of "open" healing, and he considers that in such cavities the potentiality for recrudescence remains persistently high In a large number of resected specimens showing openly healed cavities Medlar found what he judged were abnormal air spaces of non-tuberculous origin These he prefers to designate "developmental bronchiectasis" From his findings he is convinced that these pre-existed in the area adjacent to healed tuberculous lesions, where their presence is purely coincidental

We are now detecting the "vanishing lung" phenomenon increasingly often, and this remarkable increase, associated with many different pulmonary conditions, cannot be explained by Medlar's interpretation It is hardly conceivable that in so many cases pre-existing developmental anomalies could merely by chance be associated with lung areas affected by various other pathologic conditions

The concept of "developmental lung defects" was described by us[22] long before Medlar reported his studies We regard his findings *as conclusive confirmation of our concept of the* rôle of "acquired lung defects" in the pathogenesis of observed abnormal air spaces of the lungs We believe that such defects are due *to disturbance of the visceral function* of the lungs[23] caused by *damage* to the lung parenchyma in many different disorders These are quite like the "developmental defects" produced by *pathological changes in the* lungs during the postnatal period of development or during the period of the involution in advanced age The "vanishing lungs" phenomenon observed *in the whole gamut of pulmonary* diseases,[24] is reasonably explained by our concept of "lung defects" of developmental, acquired, and involutional origin

The practical problem of clinical management of abnormal air spaces is obviously far more complex No clinical criteria exist by which we can definitely *ascertain the nature of abnormal air spaces* in any given instance In cases of pulmonary tuberculosis the sputum is usually negative as a result of prolonged chemotherapy *It is certainly not possible to distinguish radiographically* between thin-walled tuberculous cavities and abnormal air spaces of non-tuberculous origin As we have indicated in these cases even the histological features *are subject to different interpretations* Those who oppose resection may now find support from Medlar's interpretation Assuming the presence of developmental anomalies which have long pre-existed, they are justified in treating such residues expectantly, and rely on long-term chemotherapy to take care of the tuberculous foci We advocate resection because in our experience when "lung *defects*" become clinically manifest it is usually because of progressive distension due to complicating obstructions[22] which are apt to give trouble later With Medlar we believe that recrudescence of true tuberculous cavities *is common* even after prolonged chemotherapy

In some instances obstruction by unsuspected early bronchogenic cancer has been revealed by resection of such abnormal air spaces Accordingly we feel that the *patient is better rid of areas of "vanishing lung"* sooner rather than later

EDGAR MAYER

RUPTURED UMBILICAL HERNIA

SIR,—I was much *interested in Dr de Glanville's* article (Dec 24) *because I had a case of spontaneous* rupture in an infant, which has been reported elsewhere[25]

The condition is rare but not quite so rare as Dr de Glanville suggests *5 cases were reported in this* country between 1868 and 1900,[26–30] 3 of these being described in your columns Johnson[31] in describing a case listed 17 others that had been reported, including the 5 from this country already mentioned Further cases have been reported by Turco[32] and Stein and Straus[33] This brings the total to 29, including Mr G F Parker's case[34] and Dr de Glanville's 2 cases Of these, 3 have been in infants, 2 in children, and the remainder in adults *But rupture in adults, following* ulceration of the coverings, has probably been much commoner than these figures would indicate

Whittington Hospital,
London, N 19

S L STRANGE

MEDIASTINAL SURGICAL EMPHYSEMA

SIR,—Following Mr O'Donoghue's account (Jan 28) of surgical emphysema due to a perforated duodenal ulcer, the following case report may be of interest

A man, aged 37, was admitted with the typical history and signs of a perforated peptic ulcer of two and a half hours duration At operation a small anterior duodenal perforation *with only moderate surrounding induration* was found, there was little peritoneal soiling The perforation was closed with an omental plug Postoperative progress was satisfactory until the third day, when lower abdominal distension began to develop Since this was thought to be colonic a flatus tube was passed, and then a turpentine enema given, but without relief *Oral fluids were discontinued and hourly gastric suction and intravenous therapy re commenced* The abdomen became more distended over the next two days, and on the fifth day it was noted that the patient had surgical emphysema of the abdominal wall which had spread through the mediastinum to the root of the neck Radiography confirmed the presence of mediastinal emphysema and showed free gas in the peritoneal cavity *there was no evidence of pneumothorax*

It was decided to drain the peritoneal cavity under local anæsthesia and some gas and fluid were evacuated through a suprapubic stab *No improvement resulted*, and the patient's general condition continued to deteriorate He went into severe peripheral circulatory failure and died on the sixth postoperative day

Necropsy showed that the *perforation* had given way completely and there was now a hole about $^1/_2$ in in diameter

The other is our professors Our professors possess a unique point of vantage between the preclinical and clinical fields You can divide university chairs into two main groups—those in subjects like physics and Greek, where the mere name of professor silences argument, and those in subjects like art or law, whose professors may be excellent fellows but whom one doesn't by mere virtue of their professorships regard as the best painters or counsel The preclinical subjects fall into the first group, the clinical into the second. It is not so long ago that most clinical chairs were mere pickings of the senior honorary, often a sort of graceful retirement for one who had shot his bolt (and made his pile) Even in these days of successful professorial units the independence of the others is jealously guarded (probably rightly, in the long run - a whole department of medicine is too much for one man to run) The one professor on the hospital staff who is really boss of his own whole department is the Professor of Pathology (one can say the same of many bacteriologists and some biochemists, but then this whole argument applies, mutatis mutandis, to them also) Now nearly every pathologist starts his career in a teaching department, and is well known in consequence to at least one chief And every appointment in pathology has on its selection committee at least one professor of the subject and though the local professor has only sometimes the appointment in his pocket he has at least a pretty strong veto in most cases Every candidate is then either a protege of his own, or of one of his twenty odd fellows and at least a good second-hand judgment is available in every case That is not to say selection committees never err (he who would believe that has never been an unsuccessful candidate) but the close nexus of informed opinion makes the external evidence of degrees and the like less necessary than it is in less well-knit branches of the profession

In fact, when you boil it down to its bones, we are governed more efficiently and ruthlessly than by an official College, even if almost unconsciously, by a junta consisting of nearly all our professors (we have remarkably few easy-chair men at the moment) with a few readers and some six or eight of the more active heads of non-teaching labs It s all very undemocratic and irregular And the Minister, who likes a Negotiating Body to negotiate with, may ultimately make us regularise the position But for the present it works—works in fact rather well

I began by setting forth to you, Barbara, our disgraceful state of anarchy with respect to exams and organisation and the like I've examined for you some of the alternatives and shown that our anarchy is an aristarchy and that we are little the worse in anything except self conceit for lack of degrees It is a prime function of the pathologist to recognise, more precisely than anyone else, the moment when normal hyperplasia goes beyond the limits of health Isn t it just possible that our passion for postgraduate degrees and diplomas and all that they imply is becoming just a little pathological ?

Yours

PETER DAVEY

Medical Congresses

GASTROENTEROLOGY

THE fifth Pan-American Congress of Gastroenterology was held in Havana, Cuba, from Jan 20 to 27 Delegates from the Latin American countries, U S.A , Great Britain and France joined members of the Cuban Society of Gastroenterology in discussing diseases of the liver and biliary tract, spleen, pancreas, and intestine

Non-tropical Sprue

Dr G B J GLASS (U S A) described the measurement of the hepatic uptake of radioactive vitamin B_{12} in the diagnosis of non tropical sprue The absorption and consequently the hepatic uptake of vitamin B_{12} may be defective in many conditions but sprue is unique in that the hepatic uptake remains insignificant when intrinsic principle is administered simultaneously A tracer dose of 0 5 µg of CO^{60} B_{12} is given orally with 75–100 ml filtered gastric juice This is followed by a purgative after eight hours and an enema twenty four hours later Two days after the tracer dose evidence of radioactivity is sought over the abdomen and over the liver There is no evidence of hepatic uptake of vitamin B_{12} in non-tropical sprue

Dr D ADLERSBERG (U S A) emphasised the value in idiopathic sprue of steroid hormone therapy, and in particular of the latest of these hormones—prednisolone and prednisone In 74 cases 15 mg by mouth daily led to improved absorption of fats and vitamins, with a corresponding lessening of steatorrhœa Unfortunately relapses invariably occurred one to six weeks after cessation of treatment, and other complications were ulceration and perforation of the intestine silent bone fractures and infection including pneumonia

Excretion of Uropepsin

Dr SEYMOUR J GRAY (U S A) described the dominant influence of the adrenal cortex on the stomach Secretion of gastric pepsin is closely mirrored by urinary excretion of uropepsin, which can be measured by a simple colorimetric method Changes in uropepsin excretion closely follow changes in ketosteroid excretion In healthy people the uropepsin level rises after administration of corticotrophin or cortisone increased excretion is not influenced by vagectomy Similar increases follow the stress of pain, trauma, surgery, myocardial infarction burns, or even emotion Uropepsin levels are low in Addison's disease, and a rise to normal follows treatment with cortisone Low levels are also found in myxœdema pernicious anæmia, carcinoma of the stomach, and cirrhosis of the liver, and after gastrectomy In contrast, uropepsin levels are high in patients with peptic ulcers This quantitative test has therefore been employed in distinguishing benign from malignant gastric ulcers, and in differentiating the bleeding of œsophageal varices from that of peptic ulcers

Serum-iron Levels with Jaundice

Dr V BEATO and Dr M ESCALONA (Cuba) have found the fasting serum iron level of some help in distinguishing obstructive from hepatocellular jaundice Compared with their normal values of 96–160 µg , the serum-iron level is often elevated in hepatitis, but is usually unchanged in obstructive jaundice and hepatic cirrhosis They suggested that the test may be helpful in cholangiolitic hepatitis when other liver-function tests are negative

Portal Cirrhosis

Dr B SEPULVEDA (Mexico) stressed the synergistic role of alcoholism and malnutrition in the ætiology of portal cirrhosis In a series of 119 patients with this disease alcohol or malnutrition alone was a contributory factor in 6% and 3% respectively, but combined they were significant factors in 83%

Œsophageal Varices

Dr R YAZIGI (Chile) underlined the poor prognosis of the cirrhotic with intractable jaundice His figures also revealed that in a series of over 600 patients with portal cirrhosis only 36% bled from proven œsophageal varices Bleeding varices need expert management early to reduce the mortality of 40% cited by Dr C FLOOD (U S.A), who suggested that this high figure was due to severe hæmorrhage before the patient reached hospital, or alternatively to complicating hepatic coma That hepatic coma is a significant factor was made clear by his much smaller mortality-rate of 17% for bleeding due to extrahepatic portal hypertension In his hands management *is based on* early blood transfusion and early balloon tamponnage to stem the bleeding In contrast, Dr R R LINTON (U S A) advocated immediate ligation of the œsophageal varices Of a small group of patients treated in

Obituary

JOHN ALEXANDER SINTON

V C, O B E, M D, D Sc Belf, F R S, D L

Brigadier Sinton, who died on March 25, was the first man to gain both the Victoria Cross and the fellowship of the Royal Society The first of these distinctions was awarded in 1916 for his personal qualities and the second in 1946 for his scientific attainments

He was born in British Columbia in 1884 of Ulster parents but he was educated at Belfast In 1908 he graduated M B with first-class honours at Queen's University, and he held appointments in the pathology department there and at the Liverpool School of Tropical Medicine As he did not join the Indian Medical Service until 1911, his age at entry was above average and his opportunities for appointment to the highest ranks were correspondingly reduced In his earlier years in India he was medical officer to the 31st Bengal Lancers, where he was enormously popular with all ranks and their families Soon after the outbreak of war in 1914 he saw active service in Mesopotamia and he was four times mentioned in despatches before the engagement in 1916 in which he was awarded the V C for "outstanding courage and devotion to duty" He was invalided to India in 1916 and served on the North-West Frontier until 1921, for his work there he was appointed O B E and again mentioned in despatches A third of his working life was thus spent on active military duty in war

In 1921 he began in earnest his career in medical research when he was seconded to the Indian Research Fund Association to take charge of a special inquiry into the treatment of malaria Later, a malaria treatment centre was started at Kasauli, Punjab The experiments carried out there under his direction placed the therapy of malaria, and particularly the evaluation of antimalarial drugs, on a new and rational basis One of the most important results of this work was the recognition of the value of pamaquin in the prevention of relapse in *vivax* malaria He was not, however, wholly preoccupied with his studies on the treatment of malaria and he also took charge of the Central Malaria Bureau and later the entomological section of the Central Research Institute, Kasauli

In 1927 a separate malaria research organisation was set up in India and Sinton became first director of the Malaria Survey of India He gathered round him a team of outstanding workers and was their undoubted leader and inspiration until he retired in 1936 The headquarters of the survey was in Kasauli, in which pleasant hill-station the British Army had its Malaria Treatment Centre, where cases of persistently relapsing malaria (almost exclusively *vivax* infections) were sent Sinton worked in close collaboration with the staff of this unit and A H Q in devising carefully controlled trials of different courses of treatment which it was hoped might effect radical cure Many unsuccessful attempts had been made with quinine in different combinations and dosages, but when plasmoquine was investigated it soon became evident that this drug possessed the unique property, hitherto unsuspected even by the makers, of destroying the phase of *Plasmodium vivax* which survives between relapses A series of trials led to the evolution of courses of treatment with combined quinine and plasmoquine, or, later atebrin and plasmoquine, which were adopted by the Army in India and reduced relapsing malaria to negligible figures This had an ironic if somewhat obvious sequel For lack of suitable cases, the Malaria Treatment Centre had to close, and no further controlled experiments in the chemotherapy of malaria could be carried out in these favourable surroundings In all this work Sinton played a leading part His shrewd brain was quick to grasp the significance of the results of plasmoquine treatment, and to press home the necessity of finding out by controlled trials the best way of using it Strangely enough the conclusions of the Kasauli group did not find favour in the eyes of the malaria subcommittee of the Health Organisation of the League of Nations, and plasmoquine was not widely used except in India—where it was adopted as the standard treatment—and indeed did not attract much attention until the work was repeated and the result confirmed by United States investigators during the late war

Sinton had wide knowledge and experience of all aspects of the prevention of malaria and organised many control schemes throughout India He was an able entomologist, and added much to our knowledge of the mosquitoes and also of the sandflies of India During these years he published over 200 scientific papers, many of them in the *Records of the Malaria Survey of India*, a journal which he himself founded in 1929 to provide an outlet for the work of his own organisation It soon became a journal which accepted work on malaria from all over India and beyond, and under his editorship the journal (now the *Indian Journal of Malariology*) quickly won international fame

After he retired from the Indian Medical Service in 1938 he was appointed Manson fellow of the London School of Hygiene and Tropical Medicine and adviser on malaria to the Ministry of Health But on the outbreak of war the following year he was recalled to India and posted as quartermaster to a military hospital in India a post which, reputedly, he held with outstanding success He was demobilised in 1940 on reaching the age of 55 Soon afterwards he was recalled from retirement and appointed consultant malariologist to the East African Forces and later to the Middle East Forces, where his duties were exacting The potential danger of a malaria outbreak in certain areas was great, and detailed organisation was necessary to have everything in readiness As all supplies had to come round the Cape, and 6–9 months elapsed between the placing of an order and the receipt of the goods, careful advance planning was necessary Into this Sinton threw himself with characteristic energy, and the insignificant incidence of malaria in this Force was, in no small measure, due to his expert guidance He was retired for the second time in 1944, but after serious outbreaks of malaria among our troops in Sicily and Italy he was again recalled and appointed consultant malariologist to the War Office

After his final retirement in 1945 Sinton went to live on a small isolated estate in Northern Ireland and cut himself off completely from his previous activities Instead he began to take part in public affairs, especially in those of Queen's University, of which he became a pro-chancellor He was also high sheriff of the county of Tyrone and a member of the National Arbitration Tribunal He received many academic distinctions, including honorary degrees, the Chalmers medal, the Mary Kingsley medal, and, ten days before his death, the Manson medal

To the man who had this varied and distinguished career two of his friends have paid tribute H W M writes

"Sinton had an exceptionally quick intellect and a flair for getting to the heart of any problem He was a man of the highest integrity and of great physical and moral courage He always did what he felt to be right no matter how unpopular his actions might prove to be he loathed expediency These characteristics and his uncompromising attitude sometimes brought him into conflict with higher authority, and this may help to explain the paucity of official recognition of the great work which he did On the other hand, no one could have been kinder or more understanding and considerate to his older and younger colleagues, and all who worked with him had the greatest respect and affection for him He would take endless trouble to help others, and on many occasions he abandoned his own research work for days or even weeks on end to obtain information requested from him

J S K B recalls him as tall, spare, active with unflagging energy

"Sinton (he continues) threw himself with enthusiasm into whatever work he had in hand, and did not waver until it was completed He was forthright and outspoken and did not suffer fools gladly He loved argument, and his eyes shone with the light of battle He was indeed a formidabl adversary, particularly as he was almost invariably right But he was the kindest and most generous of souls whose mind never entertained a mean thought, and whose gosp the powers given by the Act could not be exercised in respect of her, accordingly the Court had ordered her to be discharged

Lord **Goddard**, C J, agreeing, said that it was important to stress the duty of the judicial authority in deciding whether the person brought before him was a mental defective It was not enough that there should be two medical certificates, that they should have been given was a necessary preliminary to his having jurisdiction but they were not conclusive in any shape or form There had to be a judicial inquiry and the magistrate was obliged to see the person concerned In many cases the appearance and demeanour of the patient, coupled with the certificates would be enough, but his Lordship, could not believe that it would ever be sufficient for a patient who was described as a borderline high-grade mental defective that there was room for a difference of opinion amongst experts was shown by the affidavits It was for the magistrate to apply such tests and to call such evidence as he might require and it was important that he should not think that he was merely to act as a rubber stamp In the present case the court could not say that there was no evidence to support the magistrate's finding as to mental deficiency, but his Lordship agreed that the finding that the applicant was found neglected within the meaning of the Act could not be supported No doubt what was done was thought and intended to be for the benefit of the applicant, but persons of whatever age were not to be deprived of their liberty and confined in institutions merely because doctors and officials thought that it would be good for them

Mr **Justice Devlin** agreed

A Bequest and Two Claimants

A woman by her will dated Aug 11, 1953, gave her residuary estate to "the Imperial Cancer Research Fund care of the Christie Hospital and Holt Radium Institute Withington Manchester" She died in September 1953, at the time of her death she was resident at Bournemouth, but before 1950 she had lived at Liverpool The evidence was that her father had died at Liverpool of cancer, but there was no evidence that he had ever been treated for cancer at the Christie Hospital The gift was claimed by both the Imperial Cancer Research Fund and the South Manchester hospital management committee which administers the Christie Hospital under the National Health Service

Mr **Justice Vaisey**, giving judgment, said that this was rather an unfortunate case because there was no doubt that the deceased was anxious to promote cancer research Nothing was further from his Lordship's thoughts than to confuse Liverpool and Manchester, but it was alleged that those living in Liverpool knew quite a good deal about what was happening in Manchester, and that might be some explanation of the reference to Manchester in the will

Of the two claimants, the Christie Hospital had, at all material times, carried on cancer research and treatment, while the Fund was only concerned with research It was a puzzle why the deceased had used the words "care of the Christie Hospital " if she merely intended to benefit the Imperial Cancer Research Fund, it might be that those words possessed a significance which he was precluded from giving them In the decision of the House of Lords in National Society for Prevention of Cruelty to Children *v* Scottish National Society for Prevention of Cruelty to Children ([1915] A C 207) were a number of observations which applied precisely to the present case, Lord Loreburn had said there that the accurate use of a name in a will created a strong presumption against any rival who was not the possessor of the name mentioned in the will, which could not be overcome except in very exceptional circumstances In that case, as here, the name given was the true name and the name by which the institution was described in its Royal Charter His Lordship felt considerable doubt whether the deceased did not really contemplate cancer research at this particular place, but the words "care of" were not very helpful to the second claimant because they were used every day merely as part of an address He thought that the gift to the "Imperial Cancer Research Fund care of the Christie Hospital " was a gift to the research fund, although it was a curious way of doing it, a possible explanation was that the deceased gave that address because she felt sure that they would know where to send it He had come to the conclusion that her residuary estate should go to the first claimant, the Imperial Cancer Research Fund, under the gift contained in her will

Mental Defectives on Licence

The Board of Control are concerned about the number of patients who are kept on licence for long periods, and they have revised[1] the suggestions for the periodic review of these patients which they offered superintendents and hospital management committees in 1949 The board would normally expect that a patient should be discharged after a trial on licence for twelve months at most unless there are "overwhelming reasons to the contrary," and they ask that superintendents and H M C s should review the circumstances of patients at the end of one year on licence with a view to discharge Where it is not found possible to recommend discharge of a patient after eighteen months on licence, the board ask that a report giving the reasons should be sent to them Reports for patients who by March 1, 1956, had already been on licence for eighteen months or more should be sent as soon as possible and not later than Sept 30 1956

SCOTTISH STANDING ADVISORY COMMITTEES

The Secretary of State for Scotland has appointed new members to the standing advisory committees to hold office until Dec 31, 1958, and has reappointed other members whose terms of office have expired Medical members have been appointed or reappointed as follows

Medical Advisory Committee —Dr A P Meiklejohn (Edinburgh)

Dental Advisory Committee —Dr W M Gibson (Glasgow)

Nursing and Midwifery Advisory Committee —Dr N I Wattie (Glasgow)

Pharmaceutical Advisory Committee —Dr I M Macleod (Inverness)

Advisory Committee on Hospital and Specialist Services —Dr James Milne (Glasgow)

Advisory Committee on Local Authority Services —Dr Richard Scott (Edinburgh)

Advisory Committee on Health Services in the Highlands and Islands —Dr C S Sandeman (Durness) chloride anæsthesia for tiding over or for curing local pain—served us repeatedly Apart from ordinary practice, it won two 'firsts' for his old medical school, the Royal College of Surgeons in Ireland—the one a light weight boxing title in the British and Irish Inter'varsity contest where a thumb, dislocated outwards to a right angle, was made viable for a final win, the other when a key man in a short-handed basket ball team tore an adductor muscle and then returned to score after it was 'frozen'

---

[1] H M (56)25

'His kindliness was unfailing and his wit imperturbable Handing a prescription to someone of like humour during the blitz, he added 'You may not need this' as a V1 bomb came in a bee line His presence and his manual skill gained his patients' fullest confidence My own heartfelt relief at his return when I did a locum for him echoed their immense esteem His sole concern was with his patients' welfare, and in this best of senses it is true that 'no city has given birth to a man, more munificent in heart, more ungrudging in hand Sand escapes our numbering, and who shall count the glad assuagement that he brought?' "

HENRY JAMES CRAIG GIBSON

M A Glasg, M D Edin, J P

Dr H J C Gibson, medical superintendent emeritus of Dundee Royal Infirmary, died at his home in St Andrews on Jan 28 at the age of 67

He was the only son of the Rev J D W Gibson of Carmichael, Lanarkshire, and he was educated at Merchiston Castle School and at Glasgow and Edinburgh Universities After qualifying in 1914, he held house-appointments in Edinburgh Royal Infirmary On his return from war service in 1919 he took up a career in medical administration, and in 1920, while principal medical officer of Craiglockhart Poorhouse and medical superintendent of Craiglockhart Hospital, Edinburgh, he graduated M D With his appointment as medical superintendent of Dundee Royal Infirmary in 1922 he began his life's work During the 31 years of his administration the infirmary not only kept pace with the rapid developments in the older branches of medicine but successfully entered new fields The smoothness of this transition and the lively interest and support that the citizens of Dundee and its surroundings gave increasingly to their hospital were due in no small part to his energy and tact

Lannan

His colleagues hold that "his integrity and the breadth of his knowledge and experience were prime causes of the harmonious relations existing between the honorary and the salaried staff and the board of directors, and respect for his sense of judgment and his transparent honesty more than once kept bitterness from a discussion Those going to him on some official errand in which personal issues were involved found a wise counsellor and often a kindly friend His direction of the infirmary though close and detailed was based on trust of the staff and he was rarely disappointed"

Dr Gibson was always conscious that his first duty lay to the infirmary, but he served on several committees connected with nurses' salaries and other matters His initial opposition to a health service derived chiefly from his fear that the individual patient would suffer in the increasing complexities of a vast organisation, but when the scheme was introduced he endeavoured to carry over into it the best of the traditions of the voluntary hospitals He was for a time on the board of management of Dundee Royal Infirmary The interest of St Andrews University in its main teaching hospital also commanded his willing cooperation His work was widely appreciated in the university, and in 1948 he was appointed lecturer in the history of medicine In this year his history of the Dundee Royal Infirmary was published privately

His chief relaxation lay in classical studies and he made contributions to a new Oxford Latin dictionary on the basis of his studies of Latin medical works, a translation and critical examination of Anthimus gained him the history of medicine prize of Glasgow University in 19 After he retired to St Andrews in 1953 he was elected a member of the Royal and Ancient Golf Club and he also served on the council of St Leonards School Unfortunately within a year of his retirement illness curtailed his new activities, but it called out the cheerful quiet courage that illuminated his character

W G C writes

Perhaps Dr Gibson's influence was most clearly seen in the general methodical management of the patients and the hospital services, for he had the orderly brain of a business man as well as the clinical acumen of a trained physician In Scotland we have always liked our medical superintendents and men like Dr Gibson, held in respect and affection both by lay members of the board and by the medical staff justify our ideas A medical superintendent has hard tasks, and hard masters and servants, especially when voluntary contributions necessitated purse cutting, and it says much for Dr Gibson that he could refuse or agree without offence for we soon came to realise that he saw beyond the immediate request, and we saw too that his guiding interest was the true welfare of the sick

When the infirmary was taken over by the board of management, he was invaluable in advising and helping the young board Here, too, he faithfully served the hospital he loved and it was hard for him to see expansion and development outside his own domain Changes had come and he found it difficult to accept them But he left a most valuable history of the infirmary, which will show for succeeding generations the great place a local hospital had in the hearts of the people and the great voluntary services rendered by the staffs and contributors Perhaps we are gradually returning to more local administration and more local pride in our institutions If so it will be because, to many of us, places run by such men as Dr Gibson remain as happier memories

In 1917 he married Miss Christine Wilson, who survives him with a son and daughter

ERNEST JENNER WRIGHT

M B E, M R C S, D T M

Dr Jenner Wright, honorary consulting physician to the government of Sierra Leone, and a former specialist physician in the Colonial Medical Service in Sierra Leone died in Freetown in December He was 63 years of age

His father was a well-known African barrister and he was educated in Belgium He studied medicine in London at St Mary's Hospital Medical School and qualified in 1914 Two years later he joined the Colonial Medical Service and settled in Freetown As his appointments show, he won recognition as an outstanding clinician but he also found time for research into the deficiency diseases D G F M, as his contemporary in West Africa, though in another Territory, writes

"He was the first in West Africa to recognise the syndrome we know today as ariboflavinosis, with its associated neurological manifestations, as a nutritional disease He first described it in 1926 in the Annual Medical and Sanitary Report of Sierra Leone, and in 1930 it was again described in his privately printed *A and B Avitaminoses of Sierra Leone* and was mentioned in Leitch's *Dietetics in Warm Climates* His work will remain a lasting contribution to our studies in tropical nutritional diseases Later Wright, like his contemporaries, became greatly interested in the theory of the late Alfred Clark, who believed the cause of pellagrous deficiency diseases was a toxic one Clark held that the foods prepared from the staple foodstuffs such as manioc maize the millets, and sorghums still contained traces of cyanic glucosides, and these acted as respiratory inhibitors of cellular metabolism to meet this, by detoxication of the cyanic substances, there was an excessive demand on the sulphur of body protein

"Jenner Wright's name is honoured in West Africa as one of its greatest doctors He has earned a wider fame in the annals of nutrition as a contributor to our knowledge of one of the great tropical deficiency diseases"

After he retired in 1940 he served as chairman of various wage boards He was interested in numismatics and old books, and his library and collection of West African coins were extensive He leaves a widow and three daughters, one of whom is a doctor

Letters to the Editor

DEFICIENCY OF ESSENTIAL FATTY ACIDS AND ATHEROSCLEROSIS, ETCETERA

SIR,—Scant attention seems to be paid by the medical profession and by food administrators to a very important change in the dietaries of the more civilised countries that has been occurring over recent decades with increasing intensity. I refer to a chronic relative deficiency of the polyethenoid essential fatty acids (E.F.A.). It is true that the matter was raised in your columns a year ago, but then no less a person than a professor of nutrition stated[1] that such deficiency rarely if ever occurs in man; Professor Yudkin, however, has the disadvantage of not having worked upon E.F.A. Our own experimental work, humble in scope, combined with a careful assessment of the literature, has led us to exactly the opposite conclusion. The causes of death that have increased most in recent years are lung cancer, coronary thrombosis, and leukæmia; I believe that in all three groups deficiency of E.F.A. may be important. Your readers with stereotyped minds should stop reading at this point.

The most important E.F.A. is the vitamin arachidonic acid with four double bonds (tetraenoic). This can be formed in the body from the dienoic linoleic acid, also a vitamin, but vitamin B_6 is needed for the conversion.[2] The body probably has some slight ability to synthesise E.F.A., and these unsaturated fatty acids are of course easily oxidised. Oleic acid, with one double bond, can readily be synthesised in the body and for convenience I shall include it below in the term "saturated fat." For a reason that is obscure the requirement of male animals for E.F.A. is at least five times that of females.

Eighteen months ago Dr. V. Basnayake and I made the surprising discovery that in the rat, fed a diet entirely free of fats and of sterols but adequate in other respects, there was a large deposition in the epidermis of cholesterol (or more accurately of Liebermann-Burchard-positive sterols) and this was mainly esterified; after about 7 weeks of the deficient diet the esterified cholesterol was more than doubled. Alfin-Slater and others[3] had slightly earlier found accumulation of esterified cholesterol in the liver of rats on a fat-free diet, but their work had not then appeared in print; and two groups of workers[4 5] have shown that linoleic acid lowers serum-cholesterol in man. Obviously in our experiments the cholesterol was being synthesised in the body and its accumulation might have arisen for one of three reasons; these we discussed when we reported[6] our observations to the 2nd International Conference on Lipids in Ghent last July.

First, there is an enormous increase in permeability of the skin in E.F.A.-deficiency[7-9] and there is an increase in capillary fragility,[9] and therefore cholesterol might pass more readily from blood as has recently been supposed to occur in atherogenesis[10]; this we rejected because the great increase is in the epidermis and not in the dermis.

Secondly, the epidermis might be synthesising unusual amounts of esterified cholesterol; but liver-synthesis is normal in E.F.A.-deficiency.[3]

Thirdly, the cholesterol might be esterified with unusual fatty acids and might therefore be less readily disposed of from tissues.

We obtained evidence that this is true. Cholesterol is normally esterified mainly with unsaturated fatty acids[11] and when—as in our experiments—these are extremely deficient in the body it is esterified with much more saturated fatty acids synthesised in the body from carbohydrate. Thereby, I believe, abnormal esters are produced which tend to be deposited in tissues. Such deposition would be enhanced by a diet relatively high in saturated fat or high in cholesterol (which increases the dietary requirement of E.F.A.[12]). A diet deficient in vitamin B_6 and relatively low in arachidonic acid would act similarly, and this I believe may be the reason for the occurrence of atherosclerosis in pyridoxine-deficient monkeys[13] and possibly for the occasional hypertension in pyridoxine-deficient rats, which however we have never observed—probably because we give such rats large amounts of E.F.A. Atherosclerosis might therefore be regarded as a chronic deficiency of the vitamin arachidonic acid, this deficiency occurring in the body under the following conditions: (1) on diets very low in E.F.A. and adequate in aliments, but such diets would be exceedingly unusual; (2) on diets high in cholesterol and fairly low in E.F.A.; (3) on diets high in saturated or unnatural fats and fairly low in E.F.A., where the fats would be acting as an antivitamin; and (4) on diets deficient in vitamin B_6 and fairly low in arachidonic acid. Are such diets encountered?

DEFICIENCY OF E.F.A.

For many years and particularly in recent years animal fats and more especially vegetable fats have become increasingly oxidised and deprived of E.F.A. before being eaten. Vegetable oils, in many cases rich in E.F.A., are hardened by hydrogenation; margarine and shortenings are produced by hydrogenation of cottonseed and soybean oil, some peanut-oil, and certain other oils; during this hydrogenation much of the E.F.A. are destroyed and unnatural *trans* fatty acids are formed. Unnatural fatty acids are formed not only during hydrogenation but also during the practice of deep frying. Whale-oil is sometimes added to margarine, and this, like other marine oils of plant and animal origin which contain a variety of highly unsaturated fatty acids, is deodorised and hardened by hydrogenation. Some people who consume high-fat diets, such as some Norwegians and also Eskimos[14] uncontaminated by so-called civilisation, fare well by taking marine foods. The extraction-rate of bread is important in this context. The unsaturated fatty acids occur in the germ—wheat-germ oil is an excellent source—and therefore only small amounts survive in 70%-extraction flour. Of this remnant part is destroyed (as indeed is part of that in 80% extraction flour) by the use of the so-called "improvers." Those that are bleaching agents, such as agene and chlorine dioxide, are all powerful oxidising agents, and the other improvers are also oxidisers. As well as the chemical improvers, substances with surface active properties are added in baking, such as glyceryl monostearate, stearyl tartrate, and polyoxyethylene stearate; nothing is known of the effect of these upon the metabolism of E.F.A. Vitamin B_6 is mainly present in high-extraction flour, which is an important dietary source. Therefore the use of 70%-extraction flour tends to produce E.F.A.-deficiency partly by having a low content of E.F.A. and partly by having only about a third of the vitamin B_6 present in wholemeal flour, this vitamin being needed for the

Notes and News

THE HOUSING PROBLEM IN THE TROPICS

MODERN industry, with its demand for urban labour forces and better communications, can have profound effects when rapidly introduced into a predominantly agrarian community, and in some of the tropical and subtropical countries of the British Commonwealth the advantages of industrial development are offset by the disadvantages of breaking down tribal barriers and customs, disrupting family life, and weakening the productive resources of the countryside by attracting workers to the towns.

For the creation or preservation of a stable community, which will use its resources fully, good housing is of paramount importance. As Sir Selwyn Selwyn Clarke[1] puts it, "unsettling thoughts and desires to emigrate to other countries or to crowd into cities are much less likely to occur in the minds of those whose roots in their traditional ancestral lands are renewed and reinforced through the replacement of a leaky and insanitary hovel by an attractive dwelling in which they can feel a justifiable pride." But, he says, attention has to be paid to designing and siting the houses in line with local customs and activities, and so far as possible with individual tastes. Villages and townships should be planned to keep pace with housing development, with social centres, schools, shops, and clinics; while the establishment of crafts and small industries will further help prevent the drift to the towns.

In underdeveloped areas, land tenure is always a controversial subject; but, in Africa particularly, there are signs that government policy is changing towards giving Africans the land they occupy. Supporting this policy, the East African Royal Commission of 1953–55 contended that reserves, tribal boundaries, and the present system of land tenure perpetuated primitive methods of cultivation, which was bad for the economy and which depressed the standard of living. But, though the commission suggested certain safeguards in the transference of land between races, Sir Selwyn doubts whether these are adequate so long as the peasant, chief, or headman may sell his land to wealthy individuals or finance corporations, thereby alienating it from the community which formerly possessed it. He makes three proposals to avoid this: (1) the holder should utilise the land to the common good; (2) he should not be allowed to transfer ownership except by permission of the tribal council or coöperative; and (3) on his death his land should go to one son. (At present land is often divided among so many heirs that each becomes the owner of an inconvenient fragment.) If a man dies childless, his land should revert to the tribe or coöperative, which would be responsible for re-allotting it and making provision for his widow.

Sir Selwyn believes that housing is as much a public concern as water supplies, roads, schools, and hospitals, and like them should be a communal responsibility. In his view the State should house those who are too poor to make adequate arrangements for themselves. In underdeveloped territories the best means of doing this, he suggests, is for the central government to assume responsibility for planning and financing housing schemes and to leave the local authorities on the spot to implement, supervise, and maintain them.

Turning from housing to houses he has some equally shrewd and practical suggestions. He is insistent that there should be no more back-to-back single-room shanties but instead three-room family houses each with kitchen, bathroom, and closet. As rule-of-thumb measurements he suggests that the floor area of a living-room in the tropics should not be less than 120 sq. ft., with a window opening not less than a tenth of the floor area. But he recognises that hygiene is less likely to be accepted when it runs counter to tradition. Thus ventilation and light will be more easily introduced into a Moslem household if the window of the women's room opens on an inner courtyard and a latticed vent is placed on the outer wall. He points out that the success of a housing scheme, as of so many other projects, depends on a good start. Building materials, whether they be bricks and mortar or bamboo, palm fronds, and dried mud, are not enough. The success of a housing scheme will depend on carefully selected tenants being taught "the use and abuse of housing by a capable, energetic and tactful housing estate manager."

THE DRUG BILL

THE Committee of Public Accounts[1] has lately expressed concern at the prices paid for proprietary preparations and basic drugs, which "include a profit margin substantially in excess of that hitherto accepted as appropriate for Government contracts." A Treasury minute[2] on the committee's report expresses awareness of the need to complete promptly the negotiations with the Association of British Pharmaceutical Industry. These negotiations still centre on proprietary drugs—a field in which very great difficulties have been encountered. "It is necessary to reconcile the particular interest of the Health Service in obtaining economical supplies of drugs with the wider public interest in the continuance of a developing pharmaceutical industry." If, says the Treasury, the present negotiations cannot be concluded satisfactorily, the committee's suggestion of annual rebates from manufacturers whose prices have been shown to be excessive will be explored.

A NEW KIND OF NURSING COURSE

As a result of the Scottish Health Services Council's report[3] on the job analysis prepared by the Nuffield Hospitals Trust an experimental training course for 75 students is to be held at Glasgow Royal Infirmary. The first 25 students will begin next September. The aim of the course will be to develop leadership and judgment. It is to be financed by the Department of Health for Scotland and the Trust. It has been approved by the General Nursing Council for Scotland.

The course will be suitable for university graduates and for girls with a good higher leaving certificate or other education qualification. They should be between 18 and 25 years of age. There will be no fee, the usual training allowances (£240 during the first year of training and £250 during the second year, with a deduction of [illegible] for board, lodging, and uniform) will be paid. The students will not be required to sit the preliminary State examination and they will take their final State examination after two years of concentrated study. But they will not be eligible for registration until they have completed a third year of hospital experience during which they will act as staff nurses.

HOSPITAL COSTING

THE Minister of Health[4] has accepted the main recommendations of the working party which devised a system of costing the departments and services of a hospital.[5] These recommendations are to become effective from April 1, 1956. The new method should, in the Minister's view, "be a substantial further aid to efficient and economical administration."

A STUDY OF CEREBRAL PALSIED

THE British Council for the Welfare of Spastics has published several useful booklets for parents of children suffering from cerebral palsy. The latest booklet[6] is different, for most parents would find it difficult reading. On the other hand those who have to plan the education of the cerebral palsied, and their psychologists and teachers, will be interested and helped by the study of 168 Liverpool children which is described. One may question such statements as "The lesion in rigidity is believed to be in the cerebellar system," but in her own field the author writes with convincing sincerity. She has found that the Terman-Merill scale is generally satisfactory for testing these children, but she is far from ignoring the effects of such things as mixed laterality, visuo-spatial disability, and emotional disturbance. Although she may differ in details of method from some other psychologists her assessment would pass the pragmatic test—it works.

TRAINING THE BLIND

THE film *Conquest of the Dark* (16 mm., sound, 27 min.) shows the progress of a blind man through the Royal National Institute for the Blind rehabilitation centre at Torquay and the Ministry of Labour training centre at Letchworth. It emphasises the restoration of confidence, competence and sense of achievement. Copies of the film are available from the Royal National Institute for the Blind, 224, Great Portland Street, London, W.1.

atheroma is, I believe, the amount and structure of the dietary fatty acids

NEED FOR RESEARCH

You will now conclude, Sir, if indeed you have not done so long ago, that I have strayed into the realms of fantasy You will remind me that long ago Sir Thomas Browne wrote "Imagination is apt to rove, and conjecture to keep no bounds" My inclusion of "etcetera" in the title invites the scorn we so readily pour on vendors of patent cure alls I have no wares to sell The experiments to test my hypotheses are simple to devise, and for eighteen months I have hoped to be able to perform them But at that time when Dr Basnayake and I observed as we think the deposition of an unusual cholesteryl ester and the formation of unusual phospholipids we were engaged upon the ninth move of our laboratory, he did the estimations in another department while I did plumbing and carpentry Now we are engaged upon our tenth move which will be followed later by our eleventh Nomadism is incompatible with experimental science And all the time we note that these diseases of civilisation have increased, are increasing and ought to be diminished—diseases which I believe are caused by a dietary high in saturated fats and unnatural fats, and relatively low linoleic and arachidonic acids so that abnormal esters of cholesterol and abnormal phospholipids are formed in the body I have not in this letter been concerned with conditions I believe to be caused by a pure dietary deficiency of essential fatty acids, without any relative increase in saturated or unnatural fat these I consider to include phrynoderma[19] and also vesical calculus so common in the Far East, the latter particularly affecting children under the age of 10 and being far more common in males than in females[26] (7 1, which is about the ratio of the requirement for E F A) My purpose in sending you these speculations, which are supported by experimental evidence, is to try to help to prevent the devastating and usually increasing mortality in highly civilised countries from atherosclerosis and its sequelæ, from cancer of the lung and stomach, from leukæmia, from disseminated sclerosis, and possibly other diseases of civilisation There is a particular urgency in that if any part of my thesis is right it would be unfortunate to adopt flour of a low extraction-rate for three reasons first, the practice would reduce the dietary content of E F A partly because flour of low extraction has most of these removed, much of the rest being destroyed by the so called improvers, secondly, it would remove an important dietary source of vitamin B_6 this vitamin being needed to convert linoleic to arachidonic acid thirdly, it would remove, in presence of "improvers," all the vitamin E which protects E F A, and indeed this protection might account for the unsubstantiated claims of Shute and others that administration of vitamin E is useful in certain of the conditions in which I suggest deficiency of E F A is important You, Sir, have consistently opposed any such retrograde step[27], when Professor McCance and Dr Widdowson on the basis of their short-term experiment upon children in Germany pronounced[28] that "general information and also scientific information had been wrong in laying so much emphasis on the value of high extraction [bread] for all persons under all conditions" you rightly concluded "we maintain unrepentantly that, when it is a question of altering what has been a staple food for a very long time, the onus of proving advantage lies on those who wish to make the alteration not on those who oppose it" To revert to flour of a lower extraction-rate fortified with only three nutrients would I fear be likely to increase these diseases of civilisation in this country And let us not rush into "fortifying" low-extraction flour with arachidonic acid until we are sure that this will not produce cataract or have other disadvantages With no sympathy for long-haired naturalism, I humbly plead that we should give more thought and perform more research before extracting and "improving" wheat, manufacturing unnatural fats that then appear in margarine (which could otherwise be an excellent food) and before foisting upon the public sophisticated fodder which it unsuspectingly accepts "Truth," wisely wrote Leonardo "is the daughter of Time and not of Authority" But time is fast carrying away—unnecessarily—increasing numbers of the greatest persons I am sure you, Sir, will agree that research upon the problems I have mentioned is worth while, particularly at a time when we are trying to determine correct policy regarding the desirable extraction-rate of flour

CONCLUSIONS

In summary my thesis is that the dietaries of the more highly civilised countries are becoming increasingly deficient in the essential polyethenoid fatty acids (the vitamin arachidonic acid which in presence of vitamin B_6 can be formed in the body from the vitamin linoleic acid) and increasingly rich in more saturated fatty acids and unnatural fatty acids which may act as antivitamins This disastrous change arises partly from processes of manufacture such as the hardening of fats, and partly from the use of low-extraction flour "improved" with oxidising agents Since the requirement of males for E F A is much greater than that of females the consequences are more serious in males These consequences may include the following

1 Cholesterol becomes esterified with abnormal or unusually saturated fatty acids and these abnormal esters are less readily disposed of and so cause atheroma

2 Phospholipids (such as phosphatidyl ethanolamine) contain abnormal or unusually saturated fatty acids, and these abnormal phospholipids being less readily disposed of, are retained in plasma and increase the coagulability of blood thereby contributing to *coronary* and cerebral thrombosis

3 The deficiency of normal phospholipids in the epidermis and gut makes these structures faulty, and this may contribute to the incidence of seborrhœic eczema and peptic ulcer

4 The similar deficiency of normal phospholipids (or presence of abnormal phospholipids) in the nervous system causes defective structure including demyelination which may cause disseminated sclerosis and possibly mental disease

5 Deficiency of polyethenoid fatty acids may increase susceptibility to noxious agents including the carcinogenic effect of X irradiation and chemical carcinogens, the former, taken in conjunction with increased presentation of the carcinogen may account for the increased incidence of leukæmia and the latter for the increased incidence of carcinoma of the bronchus and for the predominance of carcinoma of the stomach in males

6 If further experimental work gives any support to these broad conclusions steps should be taken to increase the dietary content of polyethenoid fatty acids, and perhaps to decrease the content of unnatural fatty acids bread and flour of high extraction without added oxidising agents and margarine and shortenings made with less hardening of fats, would be important factors in thus decreasing some very serious diseases of civilisation

The Duke of Devonshire has been elected chairman of the grand council of the Campaign in succession to the late *Lord Horder*

Society of Chiropodists

The annual dinner of this society will be held on Friday, April 27, at 7 P M , at the City Hall Cardiff under the presidency of Mr J H Hanby, F CH S

World Health Organisation

The ninth World Health Assembly is to be held at Geneva from May 7 to 18 At the same time the World Federation of United Nations Associations is holding its seventh seminar on the World Health Organisation Further information about the seminar may be had from the federation, 1, Avenue de la Paix, Geneva, Switzerland

Ergonomics Research Society

On April 16 to 19, at Bristol University, this society will hold a symposium on Human Factors in Road Transport Further particulars may be had from H Murrell, Department of Psychology, 22, Berkeley Square, Bristol, 8

European Society of Hæmatology

This society will hold a congress in Copenhagen from Aug 26 *to 31, 1957*, under the presidency of Dr J Bichel The secretary general is Dr Aa Videbæk, Blegdamsvej 11, Copenhagen, Denmark

International Congress of Internal Medicine

The *4th International Congress of Internal Medicine* is to be held in Madrid from Sept 19 to 23 The main subjects chosen for discussion are the rôle of the adrenals in the pathogenesis and evolution of internal diseases, and bronchial asthma and emphysema

Wessex Rahere Club

A dinner of this club will be held at the Clarence Hotel, Exeter, on Saturday, April 28 Membership is open to all Barts men practising in the west country The hon secretary is Mr A Daunt Bateman, 11, The Circus, Bath

N A P T Travelling Fellowship

The Scottish branch of the National Association for the Prevention of Tuberculosis is offering a postgraduate travelling fellowship (£250) Doctors working in Scotland on tuberculosis are invited to apply before June 30 Full details may be had from the Scottish secretary, N A P T , 65, Castle Street, Edinburgh, 2

Reciprocal Agreement with New Zealand

An agreement on social security between the United Kingdom and New Zealand came into operation on April 1 From that date, people in this country are able to draw National Insurance benefits by virtue of their residence in New Zealand Anyone who wishes further information should apply to a local office of the Ministry of Pensions and National Insurance

Indian Medical Service Dinner Club

The annual dinner of this club will be held at the East India and Sports Club, St James's Square, London S W 1, on Friday June 8, at 7 30 P M Tickets may be had from the secretary of the club, medical board room Commonwealth *Relations Office, Matthew Parker Street*, S W 1

Oxford Medical Publications

Dr J C Gregory has been appointed head of the medical department of the Oxford University Press and will be responsible for Oxford Medical Publications Mr G T Hollis, who has held this position for 27 years has retired owing to ill health but will continue to act as an editorial consultant The department has now moved to Amen House, Warwick Square, London E C 4

International Congress of Gastroenterology

A meeting of the Association des Societes Europeennes et Mediterraneennes de Gastro Enterologie will be held from *July 18 to 21 at the Royal* College of Surgeons of England, Lincoln's Inn Fields London W C 2 under the presidency of Dr Thomas Hunt The subjects chosen for discussion include ulcerative colitis, pre malignant conditions of the gastro intestinal tract and non malignant diseases of the œsophagus Membership is open to all interested and forms of application may be had from the hon secretary, Mr Hermon Taylor *London Hospital, E 1*

General-practitioner Clinical Assistants

4 general practitioners have been appointed as part time clinical assistants to the West Middlesex Hospital, Isleworth and 2 to King Edward Memorial Hospital, Ealing For the 6 posts 26 applications were received

Proposed Closure of a London Hospital

The North East Metropolitan Regional Hospital Board has invited the London Executive Council to comment on a proposal by the board to close St George in the East Hospital London, E 1 *on July 31 this year In a letter to the council* the board points out that since 1948 there has been a shift of population towards the periphery of the region At St George-in-the East the demand has steadily lessened and there has been increasing difficulty in staffing the hospital adequately The board is satisfied that other hospitals (of which there are several) in the area can take over the work without inconveniencing the public At a meeting of the London local medical committee on March 27 the following resolution was passed *nem con*

> That in view of the grave difficulty in securing hospital beds in London for patients who need them probably greater now than at any time since the National Health Service started the London local medical committee protests most strongly against the proposal to close St George in the East Hospital
>
> That the Minister of Health be asked to receive a deputation from the committee

indicates that there is less postoperative trouble with the Billroth-I procedure, and I feel we should not condemn a cart load of apples because of one dubious basketful.

If leakage is a worrying factor it may be worth trying my present regime of a resection of the duodenal ulcer with low partial gastrectomy of about a third, vagotomy, and Billroth I anastomosis. This is giving promising results both in function and in freedom from recurrence. Of over 100 patients hitherto treated in this way 45 were operated on over two years ago. So far there have been no recurrent ulcers, and the functional results are my best to date. Though it is early days to consider recurrence rate, this operation does not appear to produce regurgitation of bile, possibly because the low resection, and so greater residual stomach, does not open out the œsophago gastric angle as do many high gastric resections. If one feels strongly that it is absolutely essential to anastomose the stomach remnant to jejunum, I am quite sure that the Roux en-Y anastomosis of Schofield and Anderson[3] will almost certainly be followed by freedom from bile regurgitation. I have seen, at a demonstration by Mr Schofield, 12 patients, who had vomited bile severely after Polya procedures, completely cured by this operation.

It would be a pity to retreat once more into a maze of afferent loops, to flounder again into bogs of bile, and then perhaps to sink into unwanted drowsiness and sleep, now that we are just fighting free from it all.

Oxford G. E. MOLONEY

ACUTE TUBULAR NECROSIS OF THE KIDNEY FOLLOWING ABORTION

SIR,—The article by Professor Bull and his co-workers (Jan. 28) raises interesting points, some of which I have discussed elsewhere.[4]

It is notable that in all 13 cases the abortion was induced. It may be inferred that no case following spontaneous abortion was seen. This is in keeping with the other recorded cases of a similar nature. Likewise, I found no case of significant renal failure in over 20,000 consecutive cases of abortion admitted to the three Dublin maternity hospitals. (Induced abortion is very rare in this city.) On these grounds I suggest that the syndrome might be more properly alluded to as "acute tubular necrosis of the kidney following induced abortion."

Of the patients treated by Professor Bull, 8 admitted to injecting a *soapy solution* into the uterus and 1 to the use of a vaginal douche, the nature of which was not stated. The method used to procure the abortion was not given in 3 cases. In only 1 case was an instrument used—and this by a trained nurse; the additional use of a douche, possibly 'Dettol,' seems likely here. The employment of soapy solutions is an impressive feature of the recorded cases of renal failure following abortion, so common indeed that the solutions must be suspected of being directly implicated in the renal damage. Professor Bull and his colleagues may be in a position to provide a control series where the abortions have been procured by instrumentation alone.

Abruptio placentæ is the obstetrical complication with which renal failure is most commonly associated. The placenta is formed about the end of the first trimester; hence *classical examples of abruptio placentæ arise in the middle months of pregnancy.*[4] This is an entirely different clinical syndrome. For this reason the use of the term "abortion" for termination of pregnancy before the period of viability is misleading. A clear distinction should be drawn between the termination of pregnancy before and after the formation of the placenta. This distinction, particularly in the present context, is far more important than the arbitrary period of viability, which has no scientific basis.

In all the fatal cases, and therefore presumably in all those where the patient survived, the renal lesion was *tubular* necrosis as distinct from cortical necrosis. This suggests that the lesion may be due to a toxic agent acting directly on the tubules, whereas in abruptio placentæ the renal damage is presumed to result from vasospasm. If this be so, the tubular lesion in cases of abortion may be always reversible, while steps taken for the relief of vasospasm may be expected to be ineffective.

In conclusion, I suggest that the renal failure following induced abortion is not related to intercurrent factors—e.g., shock—but is due to the direct toxic action of, usually, soap solutions. The syndrome may have no obstetrical basis, the pregnant uterus being merely the portal of entry for a toxic solution. It seems to be the *soap, and not the abortion,* that causes the renal damage.

Dublin K. O'DRISCOLL

A NEW WAY OF TREATING FLAT FEET IN CHILDREN

SIR,—Mr Helfet's article under this title (Feb. 11) interests me greatly; but what Mr Helfet describes is neither new nor a method of treating flat feet. The method of treatment was devised by Mr Franklin Charlesworth,[1] the chiropodist at Hope Hospital, Salford, who has used it for so long that I cannot remember when he started it.

The patients that Mr Helfet describes are not those with flat feet but with feet that are everted, valgus, or pronated.

As some of us in this country have been at pains to emphasise, to apply the term "flat" to these feet is completely erroneous. Many of these pronated feet have such a high arch that they are correctly described as pes cavus. The late Mr C. Lambrinudi, Mr T. T. Stamm, myself, and others have been emphasising that the problem is not that the feet go flat but that they topple over into eversion, and that in association with this eversion there is an interesting and rather complex movement at the subtaloid and midtarsal joints. This causes the inner border of the foot to become convex instead of straight or concave and makes the head of the talus sink a little. In other cases the foot topples over because there is inadequate support by the first metatarsal from atavism—i.e., shortness, looseness or instability, or a permanently elevated position (metatarsus primus elevatus). In all these conditions the lack of support in the forefoot causes the foot to roll over into eversion. Stamm[2] has also given a very vivid description of what he calls the "unscrewed" foot. *In all these varieties it seems that the important defect of the foot is in the forefoot, and it just depends on the minute details of the defect whether the end result is a pronated foot,* hallux rigidus, or hallux valgus.

It has, I think, been amply demonstrated in recent years that correction of pronated feet, when necessary, is best effected by means of some apparatus which holds the heel upright and replaces the defective support of the forefoot. That is what Mr Charlesworth's and Mr Helfet's supports do. The methods evolved by Mr Charlesworth are not expensive. Mr Helfet's methods follow very much those of Mr Charlesworth, and no doubt he will be interested to know following his suggestion in the last sentence of his article, *that* whereas in the past the material used has been plastic-strengthened hessian we are about to embark on trials of resin *impregnated laminated glass fibre.*

I would finally appeal for this to be recognised. A very high proportion of children at and soon after the time they start to walk have what we describe as pronated feet and genu valgum. In the majority it is a passing phase which requires no treatment. In a small proportion these changes will persist. As we are at present unable to tell which child will cure itself and which will not, it is wise to treat each by some simple means. Moreover, this allays the anxiety of the parent, which is perhaps the most important aspect. It is not until the child has reached the age of 6–10 that a persistent deformity needs serious consideration. Treatment then may consist in some form of surgical alteration *to the shoe, the* provision of a suitable light semi-flexible arch support, or a heel seat such as Mr Charlesworth and Mr Helfet describe. If this is persisted in, the majority of children will be cured. A very small proportion will still have the deformity and operative treatment will be necessary; but even at the age of 10–12 a condition of flat feet, using the word "flat" to mean a flattened longitudinal

morphological or functional aberrations in structures derived from this source the gonad, the adrenal cortex, and the kidney. Of course, this hypothetical unitarian concept, though supported by several facts must await further investigation and confirmation.

In 1952 Huddleston Slater[8] described an entirely comparable case in which the patient was later found to have male type nuclei.[9]

> The patient was of normal male habitus, had an empty scrotum, and had been submitted to repeated plastic operations for hypospadias. Laparotomy revealed a normally developed uterus and fallopian tubes and, at the site of the ovaries, bilateral tumours. The right tumour was diagnosed as a differentiated arrhenoblastoma (Pick's adenoma tubulare testiculare ovarii), the left as a dysgerminoma with a separate dermoid cyst. Hormonal findings suggested adrenal insufficiency.

Thus, in this case dysgerminoma was associated with another quite rare tumour, which may arise in ovary or in testis and is thus again associated with undoubted developmental anomaly of the gonads in a male. In males adenoma tubulare has been reported almost exclusively in cases of cryptorchidism or hermaphrodism. In females it is said to exert no virilising effect, but some doubt seems now justified as to whether this tumour is ever found in normal females.

Quite recently Greenblatt[10] described a patient (case 6) with feminine appearance and male skin sex, in whom a testis was removed that contained, amid non tumorous areas of immature testicular tubules, nodules of adenoma tubulare. The gonadal structure in this case is of special interest, as it seems to represent a transition between the entirely neoplastic right gonad of the foregoing case, and the non-tumorous, immature, œstrogen producing testes of the so-called "intersex males with purely feminine external genitalia."

These three cases thus present a logical sequence, extending clinically, from almost completely male to almost completely female habitus, and histologically from complete aplasia through tumorous aberration to almost normal immature structure. These facts seem to suggest that early intra uterine injury to the male fœtus may cause either complete destruction with aplasia, or variable damage with eventual tumour formation, or only functional disturbance with no gross morphological aberration of the testis.

Another rare tumour, described as common to ovary and testis, which, in the light of the foregoing, deserves our attention is primary chorionepithelioma of the gonad. The nuclear sex of patients with such a tumour should be carefully studied. This tumour, too, has been reported in conjunction with dysgerminoma, and like dysgerminoma it is often found in young patients.

We can now firmly conclude that some tumours, formerly termed ovarian, are in fact testicular. Some light is thus thrown on the curious identity of dysgerminoma and seminoma. Future studies should be directed to the question whether, taking nuclear sex as a dividing line, histological difference may be found between tumours that were formerly thought to be identical. On the other hand the evidence points strongly to a close pathogenetic relationship between dysgerminoma and adenoma tubulare.

This seems to represent a new step towards the understanding of various morphological and functional sexual deviations. Male individuals in whom a female or pseudohermaphroditic sexual pattern has developed should be carefully investigated for dysontogenetic tumours.

"L E -CELL" PHENOMENON IN CHRONIC HEPATITIS

SIR,—The article by Dr Joske and Dr King[1] in which they report finding L E cells in two patients with active chronic hepatitis contains a few points I should like to comment on.

To begin with, it is widely recognised that methods involving the coagulation of blood—such as in the Magath Winkle[2] procedure adopted in this study—have greatly enhanced the sensitivity of the original L E test. Without going here into the reasons for this,[3–7] the question has already arisen whether such techniques should not be used, "because they are so sensitive that they defeat the value of the L E cell as an indicator of acute and subacute lupus erythematosus, or whether the method should be welcomed" as a more sensitive but still reliable diagnostic procedure.[8] Also, the need for quantitation of the intensity of the phenomenon has been repeatedly emphasised, and Haserick[9] has remarked that no "aspecific" case has been reported to date, with a strongly positive (++++) plasma L E test. I can add, from my personal experience, that even the degree of homogenisation of the engulfed nuclei has a very great importance, and that greatly depolymerised inclusions after the customary incubation time, with a marked "jump of coloration"[10] between phagocytosing and phagocytosed nuclear chromatin, clearly indicate a high concentration of the L E factor in the blood, and are almost invariably associated with active lupus. L.E like cells, "tartoid" cells and genuine, but generally not plentiful and seldom totally depolymerised, L.E cells—not to speak of simple nucleophagocytosis—are more frequently met with in non lupus weakly positive tests, especially by the more sensitive (and often more traumatising) defibrination techniques. In our experience, nucleophagocytosis has been frequent in febrile Hodgkin's disease.

I have accordingly suggested[11] that always at least one defibrinated and one anticoagulant test should be done, the latter preferably both by the auto and by the iso-techniques (viz, with the patient supplying both the reacting blood or marrow cells and the active plasma or serum factor, or only the latter, the buffy coat being furnished by another, if possible group compatible, individual, or even by an animal such as the dog or the horse [hetero test]). In the admittedly rare non lupus positive tests, good photomicrographs clearly demonstrating at least a couple of typical L E cells would also be desirable, since so much information as to the reliability of the report may be gained by simply inspecting these cells. Proof of this may be found in the reported finding of L E cells in the ascitic fluids of cirrhotic patients by Leoni,[12] while nothing more than tart cells and the like are depicted in his original article.

Lastly, I agree with Dr Joske and Dr King that the L E phenomenon may be the end product of an auto immune mechanism resulting from true auto-sensitisation, or perhaps simply from antibody-like globulin synthesis with an excessive and disordered immuno allergic background. In fact, I considered this working hypothesis in 1951[13] and submitted it more fully in 1952,[14] 1953,[15,16] and 1955[7,17] This immuno allergic reaction would seem to develop spontaneously (though it is often precipitated by drugs, stress, or infections), and to be self-perpetuating in genuine

and extreme weakness In some of our cases after a few months the clinical signs of myxoedema are beginning to appear and radio-iodine uptake studies confirm the presence of hypothyroidism

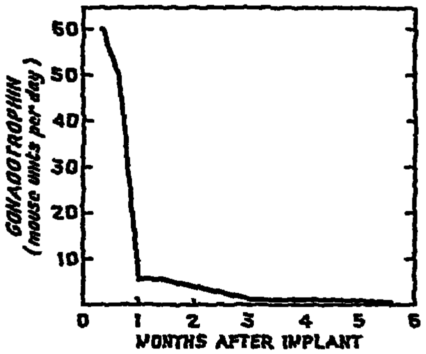

Fig 1—Case 6 urinary excretion of gonadotrophin after pituitary implantation

One of the earliest and most constant hormonal effects has been the development of diabetes insipidus which appears within a few weeks after implantation The severity of the polyuria depends on the amount of cortisone administered, and is usually not great if the dose can be restricted to 25 mg per day It can, moreover be controlled readily by pitressin given either as a snuff or as the tannate in oil The polyuria tends to diminish after a few months

Results

In the 8 cases of malignant disease other than cancer of the breast the treatment has been entirely ineffective This group included 4 patients with malignant melanoma, 3 with advanced carcinoma of the uterus and 1 with sarcoma of the breast All have died of progressive malignant disease Of the 25 patients with breast cancer 9 have died of progressive malignant disease while 9 others have shown no improvement though possibly some of them have been too recently treated for assessment The remaining 7 cases have sustained benefit as follows

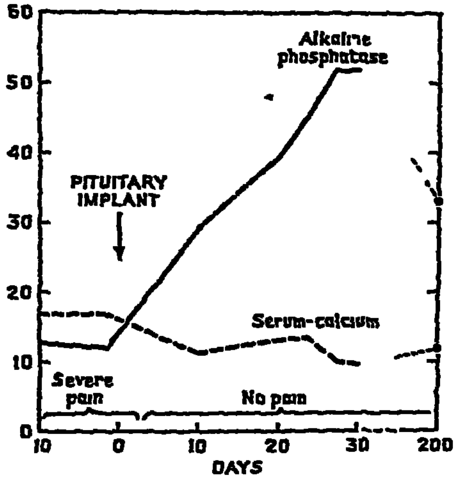

Fig 2—Case 1 blood-levels of alkaline phosphatase (King-Armstrong units) and calcium (mg per 100 ml) before and after pituitary implantation

Case 1 — A woman, aged 48 was admitted bedridden and in great pain from spinal metastases Implantation (10 mC) was performed in February, 1955 Within two days the pain had almost disappeared and within a week she was ambulant Biochemical evidence of bone regeneration was provided by the rising blood level of alkaline phosphatase and the falling level of calcium (fig 2) This patient remained well for six months free from pain and carrying out her household duties In October, 1955, she had new metastatic nodules in the mastectomy scar Bilateral adrenalectomy has now been performed

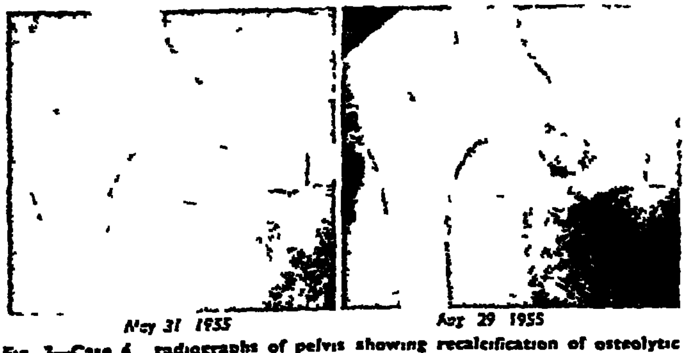

Fig 3—Case 6 radiographs of pelvis showing recalcification of osteolytic metastases following pituitary implantation on May 30 1955

Case 2 —A woman aged 49 with an untreated ulcerating breast cancer of two years duration, abruptly developed jacksonian convulsions originating in the hand area of the motor cortex The convulsions recurred repeatedly with deepening coma Seven days after the onset in March, 1955, 10 mC of radon was implanted The convulsions have not recurred, though she has frequent minor cramps and twitchings The primary growth has shown no change We recognise that there is no indisputable evidence of a brain metastasis, and, if a brain metastasis is present, symptoms due to haemorrhage into it may have undergone spontaneous arrest

Case 3 —A woman, aged 35 with multiple metastases in lymph nodes and bones, was treated by implantation of 1[illegible] mC radon in April 1955 The pain, of vertebral origin, is greatly improved Radiographs demonstrate undoubted recalcification of the vertebra, and the lymph glands appear to be smaller

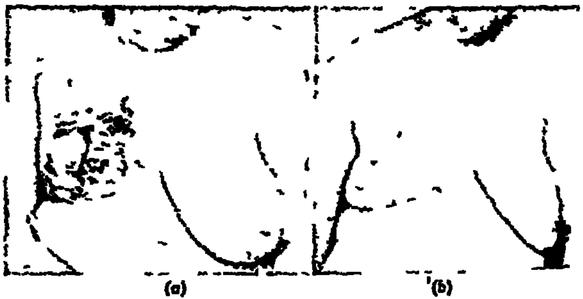

Fig 4—Case 7 clinical condition of breast before pituitary implantation (a) and four months after implantation (b)

Case 4 —A woman aged 53, with multiple pulmonary metastases, was submitted to implantation of 20 mC of radon in May, 1955 The cough of which she complained has ceased and radiographic examination appears to indicate reduction in the size and number of the metastases

Case 5 —A woman aged 63 with ulcerating nodules in a mastectomy scar and enlarged supraclavicular lymph glands was submitted to implantation (20 mC) in May, 1955 The ulcers have healed, and the underlying skin nodules have almost disappeared, and we believe that the supraclavicular glands have become smaller

Case 6 —*A woman, aged 50, with skeletal metastases,* was submitted to implantation (15 mC) in May, 1955 She gained much relief from her severe pain Radiographic examination shows undoubted recalcification of the bones (fig 3)

Case 7.—A woman, aged 66, was admitted with an untreated massive growth of the breast ulcerated over an area 6 in in diameter and with enlarged axillary and supraclavicular glands 15 mC of radon was implanted in July, 1955 The tumour is now half its original size and the ulcer has healed (fig 4) The glands have regressed

Discussion

There is no doubt that in some cases destruction of the pituitary gland by this method results in relief of pain (particularly from skeletal metastases) in recalcification of the affected bones in shrinkage of soft-tissue deposits, and even in a reduction in size of the primary growth We cannot yet determine the extent to which these responses depend on individual variations in 'hormone dependance' of the tumours or on the completeness of the pituitary destruction In all but 1 of the 7 cases described here the 17-ketosteroid excretion has fallen to below 1 mg in the twenty-four hours (see table) which suggests a fairly complete functional pituitary destruction Unfortunately in the unsuccessful cases our data morphological or functional aberrations in structures derived from this source the gonad, the adrenal cortex, and the kidney. Of course, this hypothetical unitarian concept though supported by several facts, must await further investigation and confirmation.

In 1952 Huddleston Slater[8] described an entirely comparable case in which the patient was later found to have male type nuclei[9]

> The patient was of normal male habitus, had an empty scrotum, and had been submitted to repeated plastic operations for hypospadias. Laparotomy revealed a normally developed uterus and fallopian tubes and, at the site of the ovaries, bilateral tumours. The right tumour was diagnosed as a differentiated arrhenoblastoma (Pick's adenoma tubulare testiculare ovarii), the left as a dysgerminoma with a separate dermoid cyst. Hormonal findings suggested adrenal insufficiency.

Thus, in this case dysgerminoma was associated with another quite rare tumour, which may arise in ovary or in testis and is thus again associated with undoubted developmental anomaly of the gonads in a male. In males adenoma tubulare has been reported almost exclusively in cases of cryptorchidism or hermaphrodism. In females it is said to exert no virilising effect, but some doubt seems now justified as to whether this tumour is ever found in normal females.

Quite recently Greenblatt[10] described a patient (case 6) with feminine appearance and male skin sex, in whom a testis was removed that contained, amid non-tumorous areas of immature testicular tubules, nodules of adenoma tubulare. The gonadal structure in this case is of special interest, as it seems to represent a transition between the entirely neoplastic right gonad of the foregoing case, and the non-tumorous, immature, œstrogen producing testes of the so called "intersex males with purely feminine external genitalia"

These three cases thus present a logical sequence, extending clinically, from almost completely male to almost completely female habitus, and histologically from complete aplasia through tumorous aberration to almost normal immature structure. These facts seem to suggest that early intra-uterine injury to the male fœtus may cause either complete destruction with aplasia, or variable damage with eventual tumour formation, or only functional disturbance with no gross morphological aberration of the testis.

Another rare tumour, described as common to ovary and testis, which, in the light of the foregoing, deserves our attention is primary chorionepithelioma of the gonad. The nuclear sex of patients with such a tumour should be carefully studied. This tumour, too, has been reported in conjunction with dysgerminoma, and like dysgerminoma it is often found in young patients.

We can now firmly conclude that some tumours, formerly termed ovarian, are in fact testicular. Some light is thus thrown on the curious identity of dysgerminoma and seminoma. Future studies should be directed to the question whether, taking nuclear sex as a dividing-line, histological difference may be found between tumours that were formerly thought to be identical. On the other hand the evidence points strongly to a close pathogenetic relationship between dysgerminoma and adenoma tubulare.

This seems to represent a new step towards the understanding of various morphological and functional sexual deviations. Male individuals in whom a female or pseudohermaphroditic sexual pattern has developed should be carefully investigated for dysontogenetic tumours.

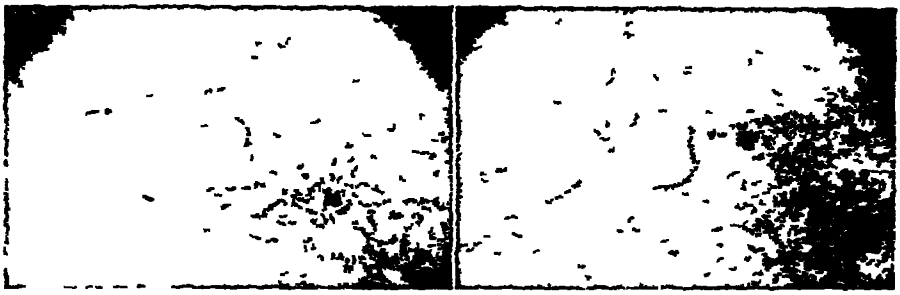

Fig 1—Retinopathy in a case of chronic type-2 nephritis A before treatment, showing papillœdema, retinal œdema, and macular star, B, after treatment with serpasil only

standing pressure was recorded as well, another three readings were taken; and in each case the lowest reading was recorded The pulse-rate was noted while the patient was recumbent

The dispensary held inert tablets corresponding to the three strengths of serpasil employed, and also made some sugar-coated phenobarbitone tablets each containing gr $^1/_2$, and some similar sugar-coated inert tablets In 9 of the cases the patients were watched for several weeks during which they took inert "serpasil" tablets and the sugar-coated phenobarbitone These tablets were then changed over to serpasil proper and inert "phenobarbitone" In all the other cases serpasil itself was given initially (to avoid delay in treatment), and if the blood-pressure fell significantly inert "serpasil" tablets were substituted in the middle of treatment Great care was taken that no patient should know when there was a change of tablets

In all cases, except those already on pentolinium or hexamethonium injections, each patient received initially serpasil 1 mg daily in divided doses, and thereafter the amount was varied according to the response Few patients required less than 0 5 mg a day, and none received more than 2 mg a day The dosage of phenobarbitone, when used, was gr $^1/_2$ t d s In the 12 patients already receiving injections of ganglion-blocking drugs the starting dose of serpasil was usually smaller than 1 mg daily and was gradually increased, according to its effect

Results

Serpasil Only

Of 41 patients to whom serpasil only was administered, the result was good in 17 (41 5%), there was no effect in 16 (39%), and the effect was doubtful or cannot yet be assessed in 8 (19 5%)

In the 17 patients who responded well to treatment, the mean diastolic blood-pressure before treatment was 145 8 mm Hg and during the trial the mean fall in this pressure was 47 4 mm Hg The highest and lowest figures ever recorded for each patient would show an even more impressive fall in pressure, but we have taken the average of readings at several consecutive attendances The use of inert tablets seemed to show without reasonable doubt that the results were in fact due to serpasil

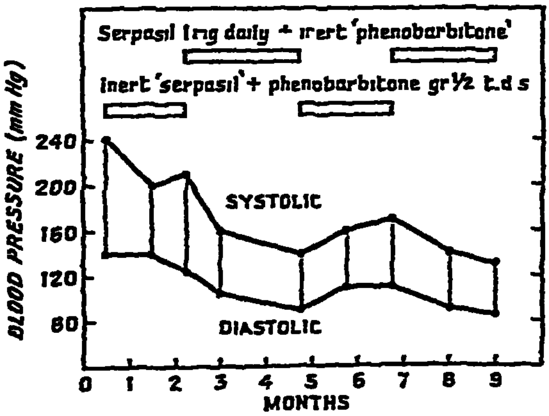

Fig 2—Blood-pressure of a patient receiving serpasil and inert tablets alternately

Serpasil Added to Ganglion-blocking Drugs

Of 13 patients in which administration of serpasil was added to that of ganglion blocking drugs, the result was good in 9 (69 2%), there was no effect in 3 (23 1%), and the effect was doubtful or cannot yet be assessed in 1 (7 7%)

These patients were all being treated with pentolinium or hexamethonium by subcutaneous injection, and their blood-pressure was therefore showing considerable diurnal variation At the time of attendance, the mean diastolic pressure *of this group, taken while recumbent* was 153 3 mm Hg After the addition of serpasil the mean fall in diastolic pressure was 29 4 mm Hg This fall is not so great as in the first group, but in 2 of these cases involved it has been possible to discontinue injections of ganglion-blocking agent, and in 3 others the dose of ganglion-blocking agent has been reduced considerably

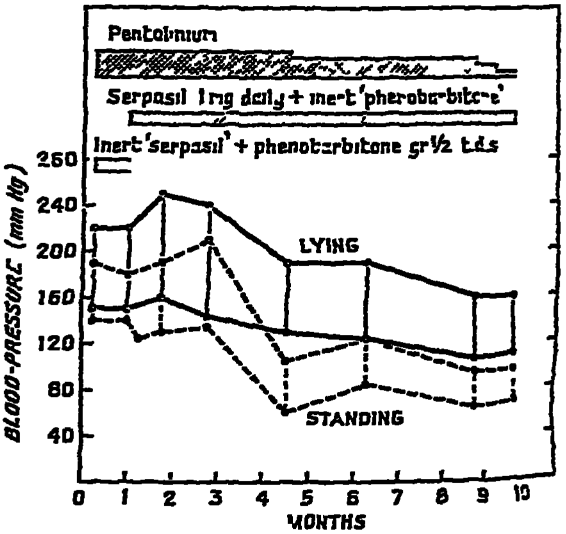

Fig 3—Blood-pressure, showing the effect of adding serpasil to pentolinium.

Further Findings in the Two Groups

Subjectively, most of the 54 patients have felt better after the treatment was started, and headaches have either been relieved completely or considerably lessened. This relief was not always clearly related to a fall in the blood pressure Vision has improved in cases where retinopathy was present, and patients unable to read a newspaper at the start of treatment have later been able to do so We have not been impressed with the objective improvement in retinopathy except in one or two cases, but cases of acute retinopathy most likely to respond to treatment were usually treated with pentolinium and are not included in this series Fig 1 illustrates severe retinopathy with papillœdema in a case of chronic (type-2) nephritis treated with serpasil only before treatment and four months later In this case the initial pressure in hospital was 190/140 mm Hg After in the duodenum. Gas under pressure, free fluid, and pus were present in the peritoneal cavity, and the presence of surgical emphysema in the mediastinum was confirmed. A careful search was made for the route of escape of the gas, but no completely conclusive evidence was discovered. There was a tiny tear in the attachment of the right coronary ligament to the diaphragm, though it was impossible to be quite sure that this was not a result of post mortem manipulation. There did seem to be a concentration of gas bubbles along the inferior vena cava. It must be presumed that the gas had in some way reached the retroperitoneal tissues through a small tear, and then tracked up along the vena cava.

The source of the intraperitoneal gas remains unknown. It could have been swallowed—which seems unlikely in view of the considerable intraperitoneal tension. It could have arisen by bacterial action in the peritoneal exudate—but no gas-forming organisms were cultured. Or it could have escaped from the bowel, the rising pressure in the lumen having possibly contributed to the breakdown of the perforation.

My thanks are due to Mr H A Haxton for permission to publish this account.

Crumpsall Hospital,
Manchester. P B LACY

INGUINAL HERNIORRHAPHY

SIR,—May I examine Mr Haxton's exposure (Feb 11) of the "fallacy" contained in my article? He states that my argument is undone by a failure to note that the linea alba is elastic in its length.

Although I do not believe it, I propose to accept Mr Haxton's suggestion for the sake of argument. The argument is that if the linea alba is elastic the whole of the lower third of the abdominal wall can descend, thus collapsing the "arch" of the conjoined tendon on to the inguinal ligament. Elasticity, however, is a passive quality needing the action of a dynamic force to demonstrate it. In this case the muscles provide the dynamic force. To achieve the desired effect a muscular mechanism for stretching the linea alba longitudinally in its lower half is needed; but I cannot invent such a mechanism. The lower half of the rectus abdominis, the most hopeful mechanism, fails because although stretching from the pubis to the lowest intersection, at the umbilicus, its pull is balanced by the upper half of that muscle, which, as far as I know, is not relaxed synergistically. In the upright position, therefore, the elasticity of the linea alba would be unused, as I am unaware of any evidence showing that the lower half of the rectus abdominis can overpower the upper half.

Let us assume, however, that the lower half of the rectus abdominis can overpower the upper half and stretch the linea alba downwards from the umbilicus, the active stretch occurring between the umbilicus and the xiphoid. This action is opposed by the contraction of those fibres of the internal oblique arising from the anterior superior spine and running horizontally to be inserted into the linea alba—unless it is suggested that they are synergistically inhibited. If these internal oblique fibres contract they will tend, as they become taut, to fix the point on the linea alba into which they are inserted, in both the coronal and the sagittal planes. Whether they are powerful enough to balance the rectus abdominis I do not know, but they would embarrass its action. The only muscle that could act without this embarrassment is the pyramidalis—a puny fellow. Therefore, even though the linea alba could be stretched very easily, it would avail the "arch" of the conjoined tendon little or nothing. As far as I know the pull of the external oblique and the internal oblique, above the level of the anterior superior spines, balance each other, and, therefore, can be discounted.

The last possibility of utilising the hypothetical elasticity of the linea alba is to return to Keith's original concept—that as the muscle fibres in the "arch" contract, it must approximate in length and position to the inguinal ligament. From observation I can state that the power of these "arch" fibres is so poor that they are unable to act in the way needed, even when stimulated alone, with the rest of the abdominal muscles relaxed.

Although the linea alba stretches with pregnancy it scarcely "twangs" back to "normal" with parturition, and I am sure that if Mr Haxton repeats my simple experiments he will find my observations substantially correct.

MEMORIAL TO SIR HUGH CAIRNS

SIR,—The Society of British Neurological Surgeons has decided to commemorate the name and work of the late Sir Hugh Cairns. The memorial will take the form, in part, of a lecture to be given in London or Oxford from time to time by eminent men whatever their country. For this it is necessary to provide an endowment fund to cover an honorarium and travelling expenses.

Our society, knowing the high esteem in which Sir Hugh Cairns was held by people in many walks of life, believe that these might wish to show their respect and, where appropriate, their gratitude by subscribing to this object. The magnificent work done by Sir Hugh in organising, with the warm coöperation of the Army authorities, the special neurosurgical skills to be applied immediately behind the battle marked a lasting advance, we venture to believe, in military surgery.

Subscriptions should be sent to the hon treasurer of our society, Mr J B Pennybacker, the Radcliffe Infirmary, Oxford.

GEOFFREY JEFFERSON
President
D W C NORTHFIELD

Parliament

QUESTION TIME

Unemployed Doctors

Replying to a question, Mr JOHN BOYD CARPENTER, the Minister of Pensions and National Insurance, said that on March 19 there were 35 doctors registered at appointments offices in receipt of unemployment benefit.

Lung-Cancer and Smoking

Mr W D CHAPMAN asked the Minister of Health what action he had now decided to take, following the reports of his advisory committees, to inform the public about the dangers of lung cancer from smoking.—Mr R H TURTON replied: I have this very important subject under urgent review. Mr CHAPMAN: Will the Minister try to tell us how quickly he can make up his mind on this very important issue and try to give us a date? Will he also take note of the feeling which exists that there should be a national campaign and that the matter should not be left to small bodies and local authorities but should be officially sponsored by his Ministry? Will he make a note of the fact that he should try to emphasise in propaganda that one of the things which people can best do to help themselves is to give up smoking in the dangerous years between 40 and 50 when they become more susceptible to the disease?—Mr TURTON: I am studying the very points which the hon Member has mentioned.

Dr BARNETT STROSS: Has the Minister yet consulted the Minister of Education to ensure that the facts are taught throughout all schools, and not only to boys but to girls as well? Will he bear in mind that this might well be the most fruitful field if the facts as we have received them are correct? Mr TURTON: The first step is to find out exactly what the facts are at present as regards research.

Overtime for Nursing Staffs

Mr ARTHUR BLENKINSOP asked the Minister what representations had been received from regional hospital boards regarding extra payments for overtime for staffs in mental and mental deficiency hospitals.—Mr TURTON *replied*: Two regional boards have expressed concern at the failure to reach agreement on overtime rates for nursing staff. Mr BLENKINSOP: Does the Minister not agree that in view of the expressed willingness of the regional hospital boards to make some extra payments for this purpose it is vital that the procedure of the Whitley Council should be speeded up?—Mr TURTON: I understand that the claim for enhanced overtime rates has been rejected by the management side of the Whitley Council.

head is slightly raised and turned to the side away from the operator

The head is draped, and an incision is made ½ in posterior to the outer bony margin of the orbit, upwards to the outer end of the eyebrow, and then along the margin of the origin of the temporalis muscle for approximately 3 in This incision is carried through the galea, and the scalp flap is reflected downwards and backwards The temporal fascia and temporalis muscle are then incised with the diathermy knife and the muscle is reflected in the same way as the scalp flap, by means of a rugine Up to this point the operation follows the lines already described in our lateral approach to the frontal sinus (Rowbotham, Clarke, and Hammersley 1955) With the perforator and burr an opening is now made into the orbit through the orbital plates of the sphenoid and zygomatic bones, thus exposing the layer of periorbital fascia Mr Hammersley's drawing (fig 1) shows the operation field at this stage

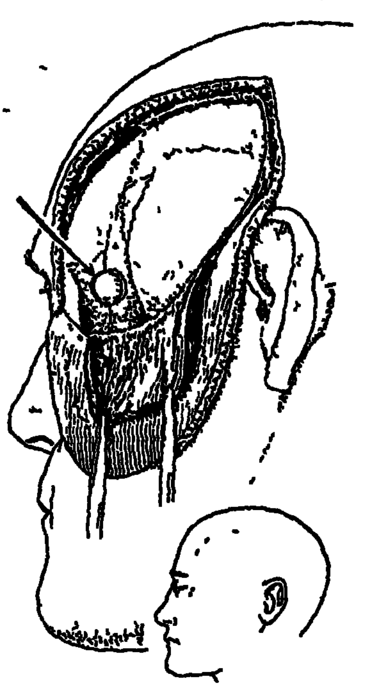

Fig 1—Exposure of periorbital fascia through burr-hole opening Small drawing shows line of skin incision

The bony opening is then enlarged with nibbling forceps, so that the roof and lateral walls of the orbit are removed In this process the dura mater of both anterior and middle cranial fossæ is uncovered The margins of the *superior orbital* fissure are preserved as is the annulus of Zinn In mild cases no more bone is taken away, but if the exophthalmos is severe the outer bony margin of the orbit is unhesitatingly removed The periorbital fascia is now freely incised, allowing the orbital contents to bulge out, and, after complete hæmostasis has been secured, the temporalis muscle, galea, and skin are closed in layers with interrupted silk sutures The wound is drained for twenty four hours

Using standard neurosurgical techniques, the operation is not difficult and can be quickly performed

During operation, and for a few days afterwards, great care is taken to protect the eye, and a pressure pad over the closed lids should be kept in position The help of an experienced ophthalmologist is of great value at this stage

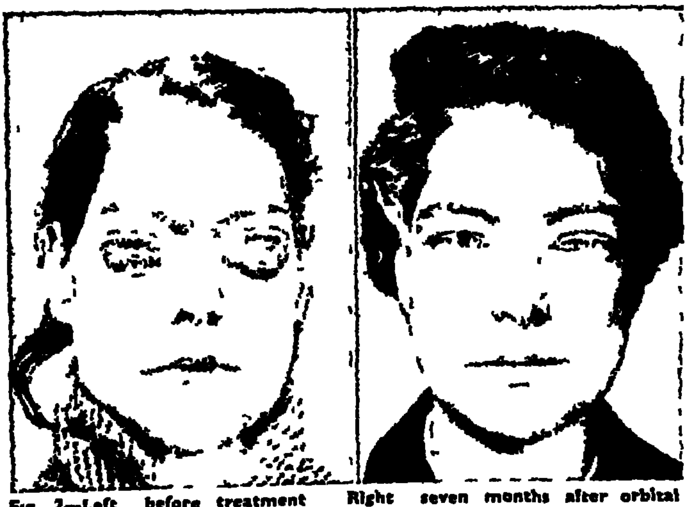

Fig 2—Left before treatment Right seven months after orbital decompression

Results

In every case the exophthalmos receded and has not recurred, no eyes have been lost A very striking finding has been the complete relief of pain in every case All our patients have commented enthusiastically on this and have considered the operation well worth while on this ground alone In no case did ophthalmoplegia progress after operation, in the 6 instances of severe ophthalmoplegia associated with diplopia there was some improvement after operation, but demonstrable ophthalmoplegia is still present This finding agrees with that of Poppen (1950), who found in his series of cases that long standing severe ophthalmoplegia was not dispelled by decompression

One of the most satisfactory cases is shown in fig 2

This woman, aged 38, first noticed exophthalmos, a small goitre, and symptoms of thyrotoxicosis in February, 1954 In August of that year thyroidectomy was performed, but despite alleviation of most of her symptoms, the eye condition progressed and she was referred to us in March, 1955 She was led into the clinic in great pain, with tears pouring down her cheeks The left cornea was completely opaque, and the right was in a similar condition except for a very small part of each upper quadrant (fig 2) The resting pulse rate was 120 per min and the basal metabolic rate +58% She was seen by Dr G O Richardson, who advised that she should be given thyroid gr 4 daily Mr J M L Howat performed immediate bilateral tarsorrhaphy

Three days later the right orbit was decompressed and after an interval of five days the left orbit was similarly treated Reduction in the exophthalmos was immediate and striking, with accompanying complete relief of pain The patient's condition in October, 1955, is shown in fig 2 The visual acuity in the right eye is 6/18, and the left cornea is clearing A few adhesions between the lids—the result of tarsorrhaphy—are still present but she can see to do her housework and look after her young family The thyrotoxicosis is controlled with carbimazole

One patient, a man, died during operation on the left orbit, the right having been decompressed a few weeks earlier

He was 67 years of age, with very severe exophthalmos Thyrotoxicosis had been treated with thiouracil to the point where myxœdema had developed Auricular fibrillation was under treatment with digoxin. Death was attributed to heart failure

This patient was an acknowledged poor operative risk, but in retrospect we feel that the myxœdema may not have been taken sufficiently into account We now do not operate in such cases until we are satisfied about the control of the thyroid deficiency

Pathology

Orbital biopsies have been carried out only occasionally, because of the danger of inflicting serious damage and because of the difficulty, in many of these cases, of identifying structures accurately In every case at operation the tissues within the periorbital layer of fascia were found to be under great tension The extra-ocular muscles were bulky and pale and there seemed to be an excess of orbital fat

In 5 patients pieces of *lacrimal gland* were removed 3 of these specimens showed chronic inflammatory changes with lymphocytic infiltration

In 5 specimens of *levator palpebræ superioris* muscle there was infiltration by lymphocytes, plasma cells, and mast cells The sarcolemma nuclei were proliferating 1 specimen of muscle had undergone replacement by fibrous tissue

Orbital fat was examined in 6 cases with normal findings in 5 In the 6th case the fat was œdematous

Our findings therefore agree with the generally accepted view that in this condition there is in life was to give ungrudgingly of his best a loyal friend, in whose company one could never be dull "

Brigadier Sinton is survived by his widow and their only child, who is the wife of a medical research-worker in West Africa

FREDERICK JAMES FITZMAURICE BARRINGTON

M S Lond , F R C S

Mr Barrington, of University College Hospital, who died on March 23, was a remarkable man He was an outstanding genito-urinary surgeon, to whom colleagues turned for help in difficult cases yet his writings were almost confined to his physiological researches He hardly ever wrote about surgery, nor did he speak publicly at meetings But the keen observation which enabled him to establish a reputation as an experimental worker was applied to every clinical case just as sharply , and, with his impeccable memory, it formed the basis of his immense clinical knowledge

The combination of laboratory research with practical surgery is often held up to young men as an ideal, but it is seldom persisted in by surgeons as they get older The picture of such a combination does not call to mind the idea of a good practising doctor but Barrington was a very good doctor His private practice was never large he was not much interested in it, and a shy abrupt manner did not help But he gave regular and devoted care to his hospital patients "To deputise for him in the outpatient department when he was away was a humbling experience Every old patient whose need was not too urgent used to get up and go away" Students saw him as a rather remote and monosyllabic personality , but to anyone who wanted to learn, and was prepared to listen, he was an exciting instructor Formal speech came to him with difficulty, and his lectures were dry in manner, lacking the vivacity of his conversation But the material of his lectures was magnificent, and notes of them were really valuable, because there was no book to take their place His operating technique was swift gentle and confident, and his cases did remarkably well The regularity of his success seemed to be based on the extreme care taken at every stage—the decision what to do, when and how to do it, followed by the aftercare never deputed

In the period 1914–41 he published what Fulton has called a series of classic papers on the physiology of micturition. These provided the foundation and most of the superstructure of our knowledge of this function and consisted in an able experimental analysis of the chain of reflex reactions that together subserve micturition Barrington never received the academic recognition these researches deserved, though those who have worked in this field have never doubted their originality and their importance "Though an unselfseeking man, he was acute enough to know this but great enough not to fester about it " His industry was immense and his knowledge of the genito-urinary anatomy of the mammalia extensive F M R W recalls how, from the pathological department of the Zoo, he used to return to the medical school "proudly bearing trophies of terrifying dimensions and of surprising origins '

Having qualified in 1907 and held a Beit fellowship, Barrington served during the first world war in cruisers in the Royal Navy, and then returned to a post on the surgical unit at University College Hospital, shortly afterwards being elected to the staff as urologist He was also appointed to St Peter s Hospital. On the outbreak of the second world war he joined the Emergency Medical Service staff at Colindale Hospital and lived at The Woodlands ' As air-raid casualties were admitted in only small numbers, a large genito-urinary unit was developed, drawing patients from University College Hospital and St Peter s and St Paul's Thus he was able to carry on his usual activities in comparatively rural surroundings, and living there with other medical staff proved congenial to him , characteristically he would remark that he had not been "so comfortable since the last bloody war " He was difficult to get to know, but once he had established a link—and usually one relating to some outdoor pursuit—that person, whatever his age, became his friend he was thereafter referred to by Barrington as "old so and so," and however youthful was treated from then on as an equal

Though his main interest outside medicine was in ornithology, he was also a keen botanist and zoologist

' During the late war," writes W E S , " he made detailed annual lists of birds and wild flowers seen at Colindale, which it was possible to print on the patients' press Characteristically he took no interest in garden flowers, regarding them as false and artificial He also enjoyed shooting and sailing and was always glad to accept an invitation for a cruise when he would spend long hours at the tiller observing sea birds, or to visit some place of interest in the country

"Apart from good dining, he cared little for personal comforts, and there was much of the ascetic in his nature five centuries earlier he would no doubt have been a monk He never drove a car, and walking even in London, was his favoured mode of transport His spare figure, with cropped head always hatless and coatless, carrying an attache case containing cystoscope, binoculars and macintosh, striding along in the Harley Street area, was familiar to many Although undemonstrative, his was a generous nature, as many hospital servants and the like in trouble well know '

It will be evident that Barrington was a many-sided man To some he was the experimental physiologist To U C H students he was " Snorker ' , he was " Fitz " at St Peter's , and he was known to many through his love of natural history He had, in fact, innumerable interests—though these did not include committees and administration

' Shy with strangers, he enjoyed with gusto meeting his friends, and there are many who will find life duller and less interesting because no longer will they see that shy angular figure One met him perhaps after a long time his face lit up some pertinent characteristic greeting would be followed by some tale or observation and after parting one had another memory of Barrington and almost always with laughter in it '

F M R W writes of the " generations that have come to know him, love him and trust him over the forty years of his association with University College Hospital and since

' Despite his somewhat farouche manner, and an occasionally alarming vocabulary drawn from the more vernacular variants of the special terminology of his branch of surgery, and at times liberally adorning his postprandial conversation no-one could be more gentle, kind, and thoughtful than he was There was neither guile nor malice in him In a sense he remained a boy all his life He loved the open air, was a keen bird watcher, and an enthusiastic, if, at times a frightening shot At a memorable Christmas shooting party at Sir John Rose Bradford s hospitable home in Wales many years ago he and I tied for bottom place "

" Although in a sense a lonely man, he was nevertheless a friendly and a happy one, and inspired great affection in very many who knew him We shall miss him deeply *Requiescat in pace* ' "

He died suddenly, in the company of friends A memorial service will be held at St Pancras parish church at 12 noon on Thursday, April 19

JOHN EDWARD O'LOGHLEN

L R C P I

Dr O'Loghlen, who died on March 8, had been in practice in South London for over twenty years and was a founder member of the College of General Practitioners After qualifying in Dublin in 1912 he continued his studies in London, Vienna. and Budapest, and he held hospital posts in Winnipeg and under the Metropolitan Asylums Board before he settled in practice in Clapham. As the stimulating letters which he contributed to our columns showed, he still found time to read widely and shrewdly in Continental as well as English journals

A K H. writes " Characters are rarer now in Medicine One of these (and a good friend) was lost to us when J E O Loghlen died It was he who taught me the importance of a close and wide knowledge of anatomy to a general practitioner, who more than anyone needs it for dealing with pain in all its moods and tenses, whether treating a disease himself or passing it on appropriately O'Loghlen felt acutely the discouragement that four changes in nomenclature have laid on those of our generation who wish to renew their anatomical youth

" Our own debt to him is great Seven years of postgraduate study in Vienna had sharpened his clinical eye and his knowledge of innumerable wrinkles One of these—his use of ethyl

DETAILS OF 14 INFANTS WHO DIED BEFORE THE AGE OF 7 DAYS WITH INTERSTITIAL EMPHYSEMA OF THE LUNGS AN MEDIASTINUM

Case no	Maturity at birth (weeks)	Condition at birth	Labour	Meconium or mucus on face at birth	Duration of symptoms	Symptoms	Age at death (hr)	Pn- thra
1	43	Normal covered with meconium	Normal	+ +	15 hr	Cyanotic attacks	24	L F
2	40	Normal	Normal		Found dead	Nil	12	L
3	40	Cried well	Normal	?	16 hr	"Whimpering"	48	L
4	40	Normal	Normal		10 hr		14	
5	42	Covered with meconium, recovered spontaneously	Normal	+ +	3½ hr	Cyanosis	21½	L - I
6	41	Asphyxia	Normal	+ +	30 min	Restless	7½	L
7	40	Normal	Normal	+	?		22	L - I
8	40	Normal	Normal		24 hr	Sloughy breathing	49	I
9	40	Normal	Normal	?	23½ hr	Cyanosis	24	
10	42	Cried spontaneously	Normal		3 hr	Cry less strong	4	L - P
11	40	Mouth full of meconium	Difficult	+ +	24 hr	Cyanosis	24	L
12	40	1–2 min before cry	Normal		Found dead	Vomited ? meconium	36	L - I
13	40	Cyanosed	Normal		30 min	"Grunting"	5½	!
14	40	Cried well after short interval	Normal	+	4 hr	"Queer noise"	10	L

were on "premature" infants and 52 on "full term" or "postmature" infants None of the premature infants died of spontaneous interstitial emphysema, although several had small amounts of emphysema produced by artificial respiration The following list shows what was considered to be the major cause of death in the 52 full term infants

Cause of death	*No of cases*
Gross congenital deformity	22
Hæmolytic disease	2
Obstetric and birth trauma	6
Thrombotic lesions	2
Infection	1
Hyaline membrane	3
Interstitial emphysema	7
Single causes	3
Cause not found	6
Total	52

This list demonstrates the known relative importance of congenital deformities and the now small importance of primary infections in the newborn Interstitial emphysema of the lung and mediastinum was the commonest single cause of death among the normally formed mature infants

Clinical History

Details of the 14 infants who died of interstitial emphysema, pneumothorax, and air block are recorded in the accompanying table

Some typical individual histories follow

Illustrative Case-reports

Case 1—A first male child, normal delivery, maturity 43 weeks At birth he was covered with tenacious meconium After being "cleaned up" he was thought to be fit, and his condition did not disturb the hospital attendants At 9 hours of age he had a cyanotic attack Three further cyanot attacks occurred before he died at the age of 24 hours This infant had no artificial respiration At necropsy a left sided pneumothorax was found The nasal passages and the trachea contained much greenish meconium like material There was bilateral interstitial emphysema of the lung, with much a at the hilum and around the vessels in the mediastinum Microscopy confirmed the presence of meconium in the alveolar ducts

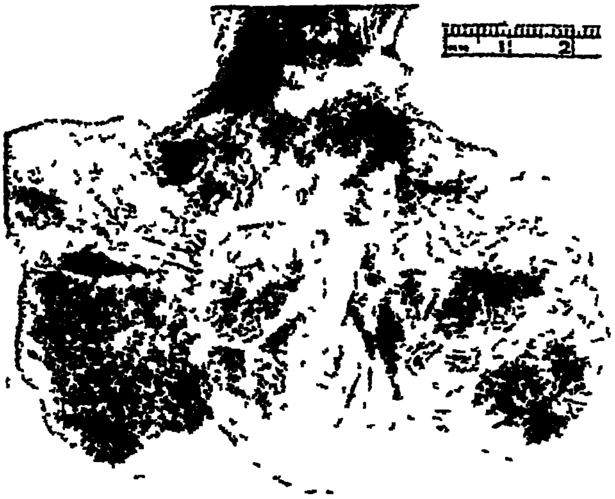

Fig 1—Heart and lungs showing extensive interstitial emphysema in both lung and large vesicles at root of left lung

Case 2.—A full term child born naturally The liquor was slightly green At birth the baby cried normally and appeared

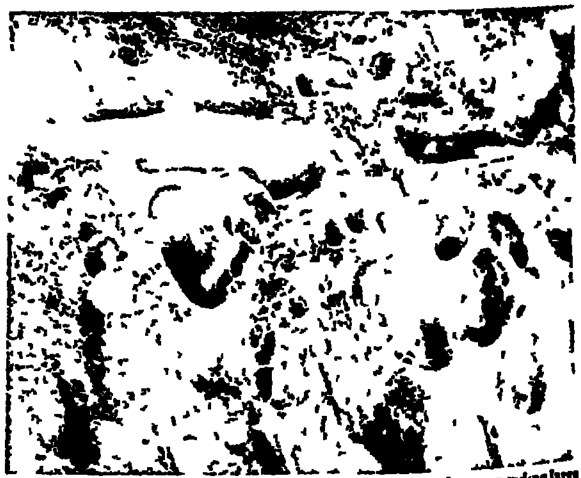

Fig 2—Transverse cut across root of lung, showing air surrounding large vessels

normal, but there were small amounts of meconium stained fluid over the face The infant was left in its cot and was considered to be completely normal, but was found dead at the age of 12 hours Necropsy revealed a left sided pneumothorax and extensive interstitial emphysema of both lungs and the hilum Microscopy showed keratinised squames obstructing the air passages

Case 3—The family doctor in sending the infant to hospital wrote "Baby born 8 P M Sunday night, second of twins born very quickly, vertex presentation Alleged to have cried well, but when seen by me at 9 P M was only whimpering was blue in hands and feet Improved in a few hours Today he has become increasingly blue *I hope it reaches you alive*" The child was dead on admission, then aged 2 days

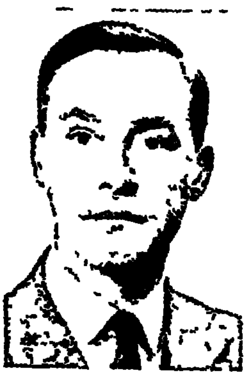
Case 4—A mature infant delivered naturally after normal labour attended by a private doctor The infant cried immediately after birth and in a few moments gave what the doctor described as "*a good yell*" Neither the doctor nor the midwife was in any way worried about the infant Three hours later the mother noticed that the infant was moaning After a further three hours, when she went to change the napkin, she saw that the infant was pale and blue When the infant was 13 hours old, she noticed a little blood

COLIN MACKAY KESSON

M D Glasg, F R F P S

Dr Kesson, assistant physician to Stobhill Hospital, Glasgow, died on March 8 He qualified from the University of Glasgow in 1939, and proceeded to the degree of M D in 1944 Four years later he became F R F P S

S A writes



[Elmore

In Colin Kesson there was something of the inscrutable, an element of mystery which created the impression of aloofness His demeanour was grave and his habit thoughtful beyond his years Such were his inherent qualities and upbringing that his name became synonymous with the virtues of deep earnestness and complete integrity His personality revealed in startling fashion the kinship of antagonistic emotions—when a gust of laughter would sweep him away and bring release from the thraldom of sombre reality In conversation he was an intent listener, but he showed , extreme diffidence in offering his own opinions unless given time for mature consideration Only those who were near him realised his intense interest in clinical medicine and the shrewdness of his judgment He had the gift of identifying himself with the patient's hopes and fears with great deftness he could strip a problem of its academic trimmings and place the patient as an individual—human and unique—in the foreground of the clinical picture For a few years he watched with philosophic calm the ebbing away of his cardiac reserve and he died in the moment when he was attaining to full maturity as a senior physician But his courage was in keeping with his record of service at Stobhill General Hospital, and it will be remembered as a fitting memorial to a gentle personality a patient teacher, and a doctor who was devoted to his calling

BERTRAM SAUNDERS

M D Aberd

Dr Saunders, who died in the Middlesex Hospital on Feb 21 at the age of 91, graduated M.B at the University of Aberdeen in 1894 After taking his M D in 1897 he came to London where he was a contemporary of Sir John Bland-Sutton as a postgraduate student at the Middlesex Hospital He held resident appointments at the North East Hospital for Children, Hackney Road and the City of London Hospital for Diseases of the Chest For many years he practised in Foley Street, a few yards from the Middlesex Hospital, and G D H, one of his younger colleagues there writes "With his old-world courtesy and kindly smile Dr Saunders was a familiar figure in the neighbourhood Towards the end of his life he had known hard times, but his great fortitude and optimism helped him to make little of this and remained with him until the end"

JOHN GORDON

M D Leeds, M R C P, D P H

Dr Gordon, reader in clinical bacteriology in the University of Leeds, died on March 6 He qualified at Leeds in 1918 and took the D P H three years later In 1925 he graduated M D with distinction A year earlier he had become lecturer in bacteriology in the university Most of his work was done in association with Prof J W McLeod, F R S He carried out many original investigations and published a large number of papers, particularly on complement and bacterial respiration He leaves a widow and two daughters

R A H writes

John Gordon was a man who was widely loved by his medical colleagues and also by the hundreds of students who passed through his hands In all his dealings he was strictly honest and thus his advice was always sought and listened to with deep respect At first sight he appeared to have a rather shy personality, quiet in speech and manner and sometimes diffident, but at heart he was a warm and likeable character In his subject he was a remarkable man He had a phenomenal memory, and having read widely in bacteriology he possessed a wealth of information which was always at the disposal of those who worked with him

Dr ARTHUR FELIX

Prof A Pijper, who met Dr Felix at the Lister Institute in 1928, writes

I can still see him, waving a paper of mine in which I had advocated complement fixation for typhoid diagnosis and taking me to task because I had not seen that my complement fixators were practically the same as O agglutinins and "why don t you people read what I write ?" The next few days I had private tuition in the mysteries of H and O and I went back to spread the gospel of receptor analysis in Africa This led to much correspondence between us, at first in German, which in the early '30s somewhat abruptly changed into English The correspondence became even more voluminous when I tried to sort out tick bite fever and murine typhus and louse typhus in South Africa, I could never have done it without Felix's constant advice and his invaluable cultures Then came his finding of the Vi antigen and the carrier that had Vi agglutinins and I hurried to confirm this on the few carriers I knew When I told him this he wrote back with characteristic generosity ' better publish quickly, I have a paper ready with several times the number of your carriers, and I shall hold back my paper, for if yours comes out after mine, it might fall rather flat '

Felix felt at home in Britain the local humour suited him, witness the remark in one of his publications that his earlier papers had "genossen allgemeiner Nicht Beachtung ' He was quick to adapt himself I remember a meeting of a research club in London where his work came under fire and the chairman asked him to say something Felix got up, smiled, shook his head, and said ' I have not the English" He acquired "the English" very rapidly ' In his last years he devoted himself with great enthusiasm to Craigie s discovery of phage typing and again we had many years of the most pleasant coöperation Personally I always looked upon Felix as an inspired man That was the only way in which I could explain how and why he collected and hung on to those famous cultures Ty 901, Ty 2, X 2, X 19, and many others, without which modern bacteriology is unthinkable And he did this, with his remarkable tenacity, through a whole world war, in a laboratory in a railway carriage, through a home coming to a totally disordered Austria, and through many years of a somewhat roving existence with scanty recognition until the Lister Institute gave him what was due to him He greatly enjoyed working there in the same way as he was quietly very proud of his election as an F.R S

Mr **FRANCIS JARDINE**, consulting surgeon to the Edinburgh Royal Infirmary and a former president of the Royal College of Surgeons of Edinburgh, died on March 27 at his home at Elie

Births, Marriages, and Deaths

BIRTHS

BINNS—On March 27, at Kingsbury Maternity Hospital London, N W 9, to Mary wife of Dr T B Binns—a daughter

JEFFERSON—On March 26 at the Radcliffe Infirmary, Oxford to Eirlys (formerly Hughes), M R C P D C H wife of Antony Jefferson F R C S a sister for Ann and Jane

SHARPEY SCHAFER—On March 28, at St Thomas s Hospital S E 1 to Dr Sheila Howarth wife of Prof E P Sharpey Schafer—a daughter

DEATHS

ROBSON—On March 22, at Bournemouth Thomas Robson M D M R C P senior physician Royal Victoria and Bournemouth Hospital and Christchurch Hospital (Corrected notice)

SANDS—On March 10, at St Ebba's Hospital, Epsom, Dalton Eric Sands, F R C P E

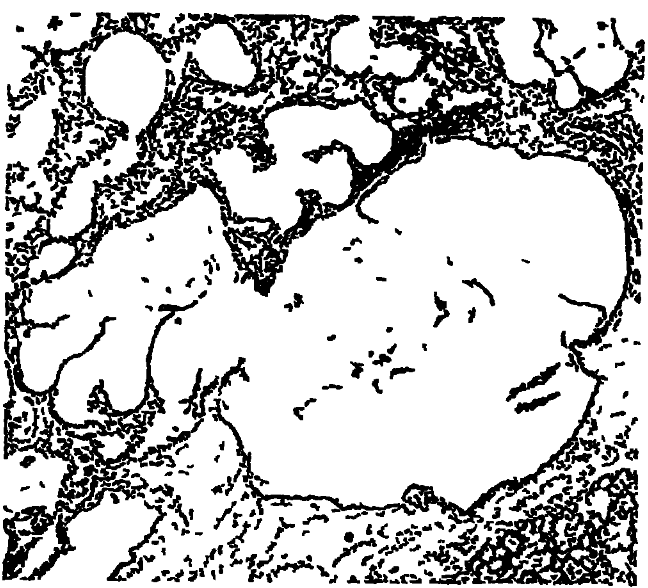

Fig 6—Distended alveoli at site of rupture into interstitial tissue of lung

found radiographic evidence of pneumothorax in 6 children in a series of 702 consecutive normal babies Holt and McIntosh (1953) state that "about 10% of newborn infants have small collections of air in the mediastinum" On the other hand, Keeffe and Jones (1951) found no case of pneumomediastinum or of pneumothorax in the routine anterior and lateral radiographs of over 4000 newborn infants Possibly the incidence of interstitial air will vary with different obstetric practice, but a general impression is gained that a variable amount of interstitial air causing no symptoms may be expected in perhaps 1 in 200 normal infants

The interpretation of free air in the thorax is difficult, for, if one accepts the findings of Davis and Stevens (1930), it would be expected to be present and of no lethal significance in about 1% of all newborn infants However, apart from the numerically greater prevalence (about 10% at necropsy), the importance of air in the thorax largely depends on its position a relatively small amount of air choking the vessels at the hilum of the lung and producing "air-block" is of considerably greater importance than an extensive pneumothorax or a large mass of air extending widely through subcutaneous tissues

Though most workers agree that a small amount of air in the chest does no harm to the infant, DeCosta (1940) was able to review about 50 case reports where this air produced symptoms which required treatment 13 cases of pneumomediastinum were reported between 1941 and 1949 (Heald and Wilder 1949), and 2 of them were fatal

Though the number of cases of spontaneous interstitial emphysema, air block, and pneumothorax reported in this country is extremely small (Rothman 1937, Yudkin 1947), this disease appears to be increasing in relative importance in normally formed mature infants within the first week after birth

The relatively high prevalence in my series is undoubtedly due to the inclusion in my material of the majority of infants dying within the City of Sheffield and to the increasing cooperation of the home doctors by their sending infants into hospital for necropsy instead of certifying the cause of death as atelectasis or as bronchopneumonia

Clinical Manifestations

The clinical histories of interstitial emphysema and death from air block seem to be consistent The children are either mature or postmature Though they cause no alarm at birth they often have much mucus in and around the nose and mouth, and they usually cry lustily Death in these cases has been preceded by either cyanotic attacks or a change in respiration, which usually becomes noisy

These symptoms have previously been well described

One of the first cases ever reported (Ruge 1878) was just like the present series It was a full term baby requiring no resuscitation, it cried lustily during the night (8–12 hours after birth) but later became cyanosed, and died next morning on the way to hospital

Silver (1939), describing the 6th recorded case, pointed out the activity of the infants and observed that infection was not an important factor in causing interstitial emphysema until after this age group

Salmon and Forbes (1943) described 3 cases of pneumothorax, all in infants who cried spontaneously In 2 of the cases meconium and much mucus were a feature at birth

Strain and Connell (1950) described an infant with spontaneous pneumothorax at the age of 4 days The infant cried spontaneously at birth and had had no artificial respiration The symptoms were cyanotic attacks The child recovered

As Salmon (1947) pointed out, the clinical picture of air-block in the newborn is unlikely to be simple The condition is the result of another disorder producing interstitial emphysema In infants with spontaneous emphysema something has produced the excessive production of mucus or the discharge of meconium during labour, and thus, though these infants are clinically apparently normal at birth, they probably have received some subclinical stress during labour

Ætiology

In the present cases microscopy revealed in the small air-passages keratinised squames derived from the fetal skin There was no evidence of infection of the respiratory tract The rupture of the alveoli into the interstitial tissue appeared to be related to the presence of mucus-carrying squames in the terminal bronchioles and alveolar ducts The interstitial air appeared to be compressing blood vessels, particularly in the hilum of the lung No air embolism (Lindblom 1924) was seen in this series of infants

Fisher and Macklin (1940) described a girl dying with interstitial emphysema in which the vessel sheaths were "air burrows in which collapsed vessels look insignificant," and Macklin and Macklin (1944) followed this with their classic study of the mechanism of death in interstitial emphysema of the lung and mediastinum They consolidated the concept of "air block" whereby death occurs from heart failure due to the obstruction to pulmonary blood flow by the pressure of air round the vessels and in the vessel sheaths The production of interstitial emphysema requires the partial obstruction of a segment of the respiratory tree and an increased expiratory effort In the cases described here the respiratory blocking appeared to be due to mucus and inhaled amniotic debris, and the expiratory force that of lusty crying

Following the work of Macklin and his colleagues, Salmon et al (1947) described 6 cases of death from air block in the newborn An interesting observation in 1 of their cases was that "although the infant's mouth and pharynx were full of mucus and meconium, respiration was prompt and spontaneous" They observed that death in these infants was from acute cor pulmonale due to compression of the pulmonary vessels causing pulmonary hypertension

Published reports on interstitial emphysema in the newborn go back to Guillot (1853) but the more recent papers contain unjustifiable statements, such as "Pneumothorax in the newborn results from the trauma of birth" (Strongin 1938) Keeffe and Jones (1951) state that, in all published cases of pneumothorax some form of artificial respiration had been administered Salomonsen (1952) states that "interstitial emphysema of the lung and mediastinum (air-block) commonly

A HOSPITAL ROMANCE

The Feminine Touch, a film from Ealing Studios which opened in London last week, is an embarrassing mixture of a little fact and much fiction The original intention may have been to show, in a lighthearted way, how the student nurse lives and works—a subject likely enough to seize the interest of the many who have ever crossed a hospital's threshold But then it seems, the producer's heart misgave him this, he may have thought, is no subject to lure the public from their home screens Anyhow, almost all else is sacrificed to follow the romance between the blonde probationer and the house-physician Despite brave talk of vomiting patients a revealing glimpse of a sluice room and one or two trips into a ward to meet selected patients, this is simply another boy-meets girl story Perhaps after all, that was the producer s intention, but we should at least have been spared the matron s Nightingale voice in this incongruous setting Acting honours are shared by Diana Wynyard an old trooper who plays the winsome matron with a blush that may owe something to Technicolor and Mandy, a young one, whose stalwart sincerity is proof against this incursion into Ealingland

AN INTERNATIONAL POSTBAG

An international corresponding club has been formed by workers in preventive and social medicine Its 42 members are drawn from teaching and research departments in fifteen different countries The club publishes twice yearly a bulletin to which members send news of the work in progress in their departments Copies, which are available to non members at 5s or $1, are issued alternately from the Department of Social and Industrial Medicine, University of Sheffield, England, and from the Department of Preventive Medicine and Public Health Cornell University Medical School, 1300, York Avenue, New York U S A

D.P M—Dorothy J Galbraith Frank Lake L C Wilson

University of Sheffield

Dr Robert Kilpatrick has been appointed lecturer in pharmacology

University of Durham

Dr C H Tonge, senior lecturer in anatomy, has been appointed reader in oral anatomy in the Newcastle division of the university

The court has approved the creation of the new post of professor of dermatology in the division

University of Liverpool

On March 27 the degree of M D was conferred on Cynthia J Discombe and the degree of M CH ORTH on I K Sharp

University of Birmingham

On Thursday and Friday, April 26 and 27, Dr H L Kottmeier, head of the gynaecological department of Radiumhemmet, Caroline Institute Stockholm will give the Ingleby lectures on Carcinoma of the Cervix and Corpus On May 14 15, and 16, Prof P B Medawar, F R.S will deliver the William Withering lectures, on Transplantation and Immunology

University of Reading

Dr Alick Elithorn has been appointed part time lecturer in psychopathology

University of Edinburgh

On July 6 the honorary degree of LL D is to be conferred on Prof G R Cameron, F R S

University of Glasgow

On June 20 the honorary degree of LL D will be conferred on Dr H C Cameron, Dr Edward Glover, and Dr T J Honeyman

University of Dublin

At a recent examination for the diploma in gynaecology and obstetrics the following were successful

Ram Lal Chugh Surendra Nath Das Bimla Devi Dugal A M MacIntosh, Mira Vinayak Muzumdar Attiya Sabir Kantilal Manmohandas Soparkar

Royal College of Physicians of London

Prof F T G Prunty will give the Humphry Davy Rolleston lectures at the college, Pall Mall East S W 1, on Tuesday and Thursday, May 15 and 17 at 5 P M, on Chemical and Clinical Problems of the Adrenal Cortex

Royal College of Physicians of Edinburgh

Prof F H Smirk will deliver the George Alexander Gibson lecture to the college, 9, Queen Street, Edinburgh, 2, on Tuesday, May 8 at 5 30 P M His subject will be the Treatment of Hypertension

Royal College of Physicians of Ireland

On March 28 the following were admitted to the licence of medicine and midwifery of the college

R R Bazeley C J Curran Usha Devi Gautama P W A D Keating Margaret M Kelly O E McCutcheon Mary R. McLoughlin W M. Reid Harry Sternberg G R Withers

Faculty of Anaesthetists

The 8th anniversary dinner of the faculty was held at the Royal College of Surgeons of England on March 21 The Minister of Health Mr R H Turton, proposed The Faculty, and the dean Dr Frankis T Evans, replied The guests were welcomed by Dr Ronald Woolmer, director of the faculty s new research department and his toast was acknowledged by Mrs Pandit, High Commissioner for India, and by Lord Adrian, O M, F.R S

Transfusion and Hæmatology Congress

The International Society of Blood Transfusion and the International Society of Hematology will hold their congress in Boston between Aug 27 and Sept 5

Medical Artists' Association of Great Britain

Forms of application for the examination for membership of this association may be had from Miss Susan Robinson (medical artist), West Middlesex Hospital, Isleworth The last day for entries is Saturday, May 26

Medical Art Society

This society is holding an exhibition at Walker s Galleries, 118 New Bond Street, London W 1 Until April 21 it will be open from 10 A.M to 6 P M (Saturdays 10 A M to 1 P M)

International Association of Gerontology

This association is holding a congress at Merano, Italy, from July 14 to 19, 1957 In connection with the congress an international symposium will take place in Venice on July 20 and 21 on medico social aspects of senile nervous diseases. Further particulars of both meetings may be had from the secretariat, Viale Morgagni 85, Firenze, Italy

TABLE I—CLINICAL DETAILS

Case no	1	2	3	4
Age (yr)	4½	8	2½	9½
Sex	M	M	M	M
Duration of disease (mos)	4	56	3	24
Blood pressure (mm Hg)	110/75	120/70	100/70	120/80
Albuminuria (g daily)	1–4	1–2	1–2	1–4
Urine	Casts no blood cells	Occasional casts, no blood-cells	Occasional casts, epithelial cells	Occasional casts, no blood-cells
Degree of oedema	Severe + ascites	Severe + ascites	Severe + ascites	Severe + ascites
Dosage of prednisolone (mg daily)	60 × 5	60 × 10, 40 × 10 20 × 10, 10 × 10	60 × 10 40 × 10, 20 × 10, 10 × 10	60 × 10, 40 × 5 20 × 10 10
Weight before diuresis (lb)	40	72	29	67
Weight after diuresis (lb)	31	57	22	53
Time since diuresis (mos)	5	4	3	1

remain free from oedema sixty to a hundred and eighty days after diuresis

The serum-albumin level rose rapidly in all 4 cases (fig 2) During diuresis the serum-albumin level was below 1 g in all 4 patients, but the level rose rapidly thereafter The higher level has been sustained by each patient (table II), but in general the optimal electrophoretic pattern was reached at the end of prednisolone treatment, and somewhat lower levels persisted thereafter The gamma globulin level rose in each case during treatment and was sustained Blood cholesterol levels fell from above 260 mg to below 150 mg in all 4 patients and have remained within normal limits The nadir of weight loss having been passed, these patients gradually gained weight without any return of oedema, probably owing to eutrophy and protein anabolism

* Level before prednisolone treatment

Discussion

Nephrosis is not rare, during the past eighteen years (1938–55) 120 children with nephrosis have been admitted to the Royal Hospital for Sick Children, Glasgow In a long-term follow up of 208 cases Barness et al (1950) found an eventual mortality of 50%, and this mortality has probably been little affected by modern treatment (Barnett et al 1952) In dealing with such a chronic and unpredictable disease it would be foolish to place reliance on a small number of cases treated for a short time Nevertheless the immediate results of prednisolone treatment are encouraging and significantly superior to those obtained with either corticotrophin or cortisone The fact that prednisolone consistently reduced th albuminuria, and caused diuresis and thereafter clinic and biochemical improvement in these patients sugge that it may prove to be valuable in therapy Th treatment is given orally is of great advantage in dealin with small children, particularly when oedema is presen

The general impression is gained (figs 1 and 2) th the patient receiving the longer courses of prednisolo improved more rapidly The mode of action of predn solone is not known, but it seems likely that albuminur is decreased either by a direct action on the nephron by the blocking or destruction of an extrarenal fact (such as an abnormal antigen antibody reaction) pr voking albuminuria It is unlikely that the action is o of simple blocking or antagonism, since the clinic improvement may take place after the hormone treatme has been stopped In addition it is possible that predn solone, which has no salt retaining activity (Bunim et a 1955), may depress the endogenous production of adren hormone and cause sodium and water diuresis resemblin a temporary " addisonian crisis " The improvement i case 2, who had had nephrosis for five years, was unex pected and the persistence of slight albuminuria w surprise

Too much attention has been paid to altering th oedema, the ascites, and the blood cholesterol and serum

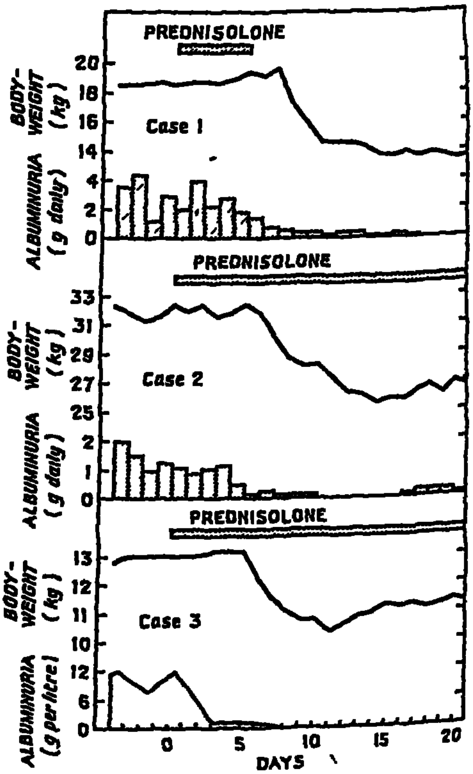

Fig 1—Relation of prednisolone treatment and albuminuria to loss of oedema and consequent loss of weight

PERFORATED ACUTE AND CHRONIC PEPTIC ULCER

CONSERVATIVE TREATMENT

HERMON TAYLOR
M A, M D, M Ch Camb, F R C S
SURGEON TO THE LONDON HOSPITAL AND KING GEORGE HOSPITAL, ILFORD

R P WARREN
M.B Lond, F R C S
LATE SURGICAL SENIOR REGISTRAR, LONDON HOSPITAL, AND KING GEORGE HOSPITAL, ILFORD

AFTER one of us reported 101 cases of perforated peptic ulcer treated conservatively at King George Hospital, Ilford (Hermon Taylor 1951), a further 99 patients (with 102 perforations) have been added to the total up to the end of 1954 We therefore had 200 cases in ten years, and the subsequent history of the majority of the survivors has been obtained

We review here the results, with special attention to the difference in behaviour between perforations of acute and of chronic ulcers, both immediately and with regard to the incidence of recurrent ulceration

Ten years ago the mortality of the aspiration method was lower than that of operative suture for which the figures at King George Hospital and elsewhere were rather unsatisfactory Since then the risk involved in surgical operations has become so small that the risk of death due to the operation itself, which the conservative method was designed to avoid, is no longer a factor in selecting treatment Indeed by 1951 the over all mortality of gastric aspiration in several hospitals was about equal to the best figures for operative suture (Hermon Taylor 1951)

The increasing safety of modern operations has led also to the practice of treating perforated ulcer cases by immediate partial gastrectomy This method averts not only the immediate complications of a sutured perforation but also the later ones from recurrence of the ulcer (Lowdon 1952, Noordijk 1953) But partial gastrectomy, though it has undoubted advantages in cases of chronic ulcers which have finally perforated, is an unnecessarily radical procedure for perforated acute ulcers, and these are generally still treated by simple suture

In our patients treated without operation, the distinction between acute and chronic ulcer at the time of admission has to be made entirely on the presence or absence of a history of dyspepsia On this criterion about a quarter of the perforations in our series have been of acute ulcers, and a clearcut difference has emerged between the results of treatment in the two groups In a word, *mortality, complications, and disability are confined almost entirely to the chronic ulcer group No patient with a perforated acute ulcer has died when treated by aspiration Only 1 has had a complication of any significance and nearly all have remained free of symptoms in the ten-year period of the trial*

Survey of Additional Cases

Errors

The serious consequences which theoretically might follow a mistaken diagnosis in a case of suspected perforated ulcer have been the focal point of opposition to the conservative method of treatment We have carefully collected all cases in which any error has been made, for however short a time

Errors have occurred in two directions (1) various other acute conditions have been diagnosed as perforations, and (2) perforations have been thought to be some other abdominal emergency

Under the first heading we have 2 cases of appendicitis and 2 cases of intestinal strangulation treated at the start by aspiration, but later by operation when the true diagnosis became clear the short delay did not prevent the full recovery of these patients 4 other patients were *not* operated on when the diagnosis was corrected Of these 4, 2 had biliary colic, 1 gastro enteritis, and 1 coronary thrombosis These patients may be said to have benefited from the conservative treatment of perforations adopted at the hospital In these 8 cases no harm has come to the patients The theoretical tragedies have not happened in practice

Under the second heading were 9 diagnoses—7 of acute appendicitis and 1 each of intestinal obstruction and perforated diverticulitis—in patients who actually had a perforated peptic ulcer They were all operated on because of the mistaken diagnosis, and 2 patients with widespread peritonitis died These 9 cases will not be included in the results tabulated here, which are those of conservative treatment only They are mentioned to complete the record of our fallibility

Mortality

93 patients were treated by gastric aspiration, with 11 deaths Of the 11 patients who died 7 were admitted moribund and could not be resuscitated, and the outcome was inevitable The 4 more debatable fatalities comprised 1 case of hæmatemesis followed by perforation 1 case *of severe bronchopneumonia with a per*foration and a small subphrenic abscess, 1 case of large subphrenic abscess, which perforated into the general peritoneal cavity, and 1 case of adrenal adenomata in a patient who was apparently convalescent but who collapsed after a simple operation to evacuate a collection of sterile fluid above the liver It is noteworthy that 10 of these 11 deaths were associated with chronic ulcers the 11th being a perforated carcinoma, none was a perforated acute ulcer The mortality is identical with that in the first 100 cases (Hermon Taylor 1951)

Complications During Treatment

Conservative treatment failed to seal the perforation in 5 cases and operation was undertaken for this reason, all 5 patients recovered Collections of peritoneal fluid were drained in 5 other cases, all during the second week after perforation This total of 10 intercurrent operations, compared with 12 such interventions in the first 100 cases, shows little change in this aspect of the treatment The important point is that in 21 of the 22 cases where operative interference was required, the perforations were of chronic ulcers An intercurrent operation was needed in only 1 case of perforated acute ulcer and that was for drainage of clear fluid from below the diaphragm on the twelfth day

Review of all Cases

In our cases, in the absence of any surgical exposure, the site of the ulcer is unknown at the time of perforation, but the history suggests whether it is acute or chronic Tables I and II, which have been drawn on this basis, show the results of treatment with regard to immediate mortality and to the incidence of recurrent ulceration in the survivors They do not include 4 cases of perforated carcinoma which occurred during the same period It will be seen (table I) that the mortality was nil in 47 patients who gave no history of previous dyspepsia

TABLE I—MORTALITY OF PEPTIC ULCER PERFORATIONS TREATED BY ASPIRATION OF STOMACH

—	Chronic ulcer	Acute ulcer
Total perforations *	143	47
Hospital deaths	20 (*14%*)	0
Survived	123 †	47

* Excluding (*a*) 4 perforations of carcinomas (2 deaths) (*b*) 9 cases treated by primary operation (3 deaths)

† 3 patients each had two perforations, patients in this group numbered 120

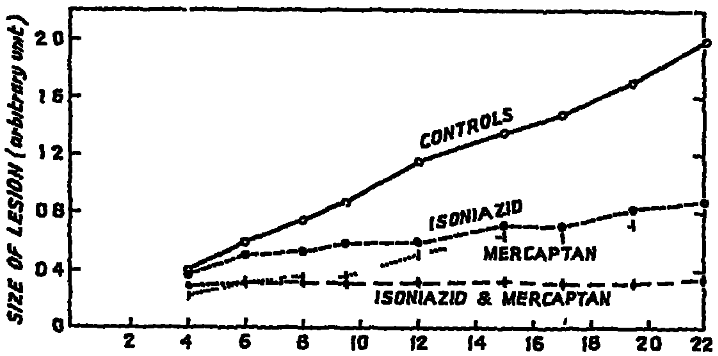

Fig 1—Development of corneal lesions in groups of mice under various types of treatment (experiment I)

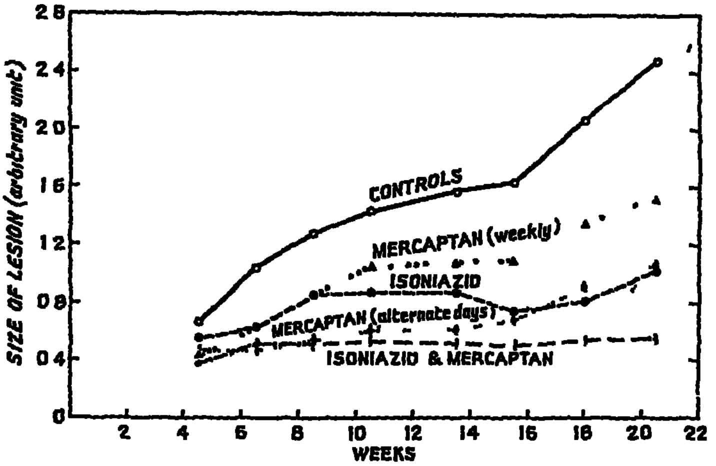

Fig 2—Development of corneal lesions in groups of mice under various types of treatment (experiment 2)

completely, because the true leprosy lesion became superimposed upon it after a latent period of 28–30 days Such a lesion first developed as a small dense focus in the area of the initial reaction, gradually progressed, became vascularised, and spread to involve more and more of the cornea Meanwhile its density further increased, and in 15 of 17 mice it spread to the sclera, which became thick and swollen

Treatment of the infected mice with the mercaptan, isoniazid, or a combination of the two resulted in lengthening of the latent period and slower development of the corneal lesions

The most striking effect was produced in experiment I *in the group of mice treated with isoniazid daily and the mercaptan every 2nd day* In this group no true lesions had developed in any of the mice up to 22 weeks after inoculation For this period only slight opacities equivalent to the initial reaction were seen in all the inoculated corneæ In the similarly treated group in experiment II, in which the mice received combined therapy of isoniazid daily and the mercaptan once a week, this complete suppression was *not* observed, yet the treatment was also strikingly effective Although true lesions developed in the cornea of all the mice and spread to the sclera in 7 of 8 mice they nevertheless remained small and progressed very slowly

In the two experiments 18 mice were treated with the mercaptan once every 2nd day In these mice there was significant delay in the development of the true lesions, which appeared after a latent period of $4^1/_2$–15 weeks They then progressed much more slowly than those of the controls, *but spread to the sclera in 15 of 17 surviving mice* (1 was killed for histology)

Administration of the drug once every week to 10 mice led to a short delay in the appearance of the true lesions, which progressed more rapidly (experiment II) than in the previous group and spread to the sclera in 9 mice

However, in comparing the activity of the mercaptan with that of isoniazid we found that the effect of isoniazid was similar to that of the mercaptan injected every 2nd day Although the lesions in the mice receiving the mercaptan every 2nd day progressed at first at a slower rate, at the 10th week in experiment I and the 14th week in experiment II they progressed more rapidly, and within about 2 weeks they were nearly as large as those in the isoniazid treated mice Since then there has been no difference in the progress of the lesions in the two groups The activity of the mercaptan injected once a week was less than that of isoniazid but still quite definite

Summary

The therapeutic effect of diethyldithiolisophthalate (compound 15688) alone and in combination with isoniazid on murine leprosy was studied in mice by the intracorneal technique

The most striking effect was obtained with the combined therapy of isoniazid daily and the mercaptan once every 2nd day, since no true lesions have developed up to the 22nd week after inoculation

Injection of the mercaptan alone once every 2nd day produced an effect similar to that obtained by the daily administration of isoniazid

We are greatly indebted to Dr G E Davies of Imperial Chemical Industries Ltd, for the supply of diethyldithiolisophthalate (compound 15688) used in this investigation, and to the Medical Research Council for defraying part of the expenses

AFIBRINOGENÆMIA IN OBSTETRICS

T B FitzGerald
D Sc , M B Birm , F R C S E , M R C O G
CONSULTANT OBSTETRICIAN AND GYNÆCOLOGIST

S H Jackson
B Sc , M B Manc
CONSULTANT PATHOLOGIST

ASHTON, HYDE, AND GLOSSOP HOSPITAL GROUP

SERIOUS depletion of the blood *fibrinogen* was first described in this country as an obstetric complication by Barnett and Cussen (1954) and Barry et al (1955), and was discussed at the 14th British Congress of Obstetrics and Gynæcology (1955) This condition is therefore *sufficiently novel and imperfectly understood to justify* the publication of further cases

Case-reports

Case 1 —Gravida 4, aged 39, admitted as an emergency in December 1953, 36 weeks pregnant by dates, blood pressure 180 100 mm Hg, with a trace of albuminuria, uterus small for duration of pregnancy Four days after admission spontaneous labour produced, by normal delivery, a live baby weighing 3 lb 11 oz Shortly before this the patient had a rigor with a temperature of 102 F The placenta

placenta, when the risk of further hæmorrhage would be greatest fibrinogen should be given in relatively large dosage just before and after completion of the third stage In case 3 the view was taken that it might be better to give fibrinogen as soon as afibrinogenæmia was confirmed by laboratory examination, to forestall any further bleeding into the uterus or into the uterine muscle, which would lead to a "Couvelaire uterus", fibrinogen was also given at delivery

Serial estimations of plasma fibrinogen taken after the first injection of fibrinogen 0 3 g gave interesting evidence of the speed with which it takes effect (two minutes or less) and of the rate at which defibrinogenation took place (from a plasma fibrinogen level of 100 mg per 100 ml to one of 46 mg per 100 ml in about two hours)

Though case 2 lost only $1^1/_2$ pints of blood by concealed hæmorrhage, whereas case 3 lost 3 pints, case 2 very nearly died whereas case 3 never reached such a serious pass It would be unwise to link this to the timing of fibrinogen injection alone, since there was delay in induction of labour in case 2, and we agree with Barry et al (1955) that such delay is harmful

The adverse effect of dextran or other plasma substitutes, which has been emphasised by Scott (1955), was not a factor in these 2 cases, because the condition was present on admission before transfusion of any kind had been given

Conclusions

In afibrinogenæmia associated with accidental hæmorrhage Schneider's views of thromboplastin induced defibrinogenation of the blood seem acceptable, but the main site of deposition may be in the intra uterine clot

The advice of Barry et al (1955) to use double strength plasma in the milder cases and pure fibrinogen in the severe case, together with the need for delivery without avoidable delay, appears very sound Our experience resembles that of Barnett and Cussen (1954) in that the massive theoretical dosage of fibrinogen may not be necessary to control hæmorrhage It seems best to administer the fibrinogen in smaller divided doses, or by continuous drip, to keep pace with the defibrinogenation, and to supplement this with a further dose just before delivery

Summary

3 cases of afibrinogenæmia in obstetric patients are described

In case 1 the patient died, and necropsy showed wide spread hæmorrhages but no clear evidence of fibrin emboli

Cases 2 and 3 were associated with severe accidental hæmorrhage, both were treated with pure fibrinogen by different methods, the merits of which are discussed

In case 3 the effect of administering fibrinogen was assessed by serial estimations of plasma fibrinogen The intra-uterine blood clot contained 63 g of fibrin, and this high figure suggests that the bulk of the fibrin may be deposited in the uterus rather than in the vascular tree

We wish to thank Dr F Stratton, Director, Manchester Regional Blood Bank, for the provision of the fibrinogen used in these cases, and Dr John Kench, of the department of pathology in the University of Manchester, for much helpful information

PREVALENCE OF CORONARY HEART-DISEASE IN ELDERLY COAL-WORKERS

ARTHUR J THOMAS
B Sc, M D Wales, M R C P, D P H
CONSULTING PHYSICIAN, UNITED CARDIFF HOSPITALS

J E COTES
M A, B M Oxfd, M R C P

I T T HIGGINS

MEMBERS OF SCIENTIFIC STAFF, PNEUMOCONIOSIS RESEARCH UNIT OF THE MEDICAL RESEARCH COUNCIL, LLANDOUGH HOSPITAL, PENARTH, GLAM

EVIDENCE is accumulating that coronary heart disease has become more prevalent in the past thirty years (Logan 1952, Ryle and Russell 1949) Some of the increase is more apparent than real, but the work of Morris (1951) leaves little doubt that the condition is commoner now than it was before the first world war The professional classes and sedentary workers are those mainly affected by the increase, and the prevalence is not generally thought to be high in miners

During the course of clinical studies of heart disease among miners and ex miners in East Glamorgan (Thomas 1956b) we have gained an impression, as have others before us (Cruickshank 1932, W E Hume cited by Cassidy 1946), that there is a high prevalence of coronary heart disease However, since the post mortem and clinical material on which such impressions have been gained may be biased by the method of selection, we have attempted to obtain a true estimate of prevalence by examining a representative sample of miners and ex-miners from a whole mining community of about 20,000 adults studied by Cochrane (1954)

We briefly describe the prevalence of coronary heart disease as shown by studies of hospital cases and necropsies, and, in greater detail, the results of the examination of a representative sample in the mining community

The phrase "coronary heart disease" is used to describe severe coronary artery disease of atherosclerotic origin, coronary thrombosis, myocardial infarction, and ischæmic heart disease due to chronic coronary insufficiency, when these conditions were of sufficient degree to produce heart disease detectable on clinical or post mortem examination

Prevalence in Hospital Cases and at Necropsy

In an analysis of 1000 necropsies on coal workers (James 1954) there were 244 cases of coronary heart disease Table I shows the age distribution of these cases

In at least two thirds of the cases (16%) the disease contributed to the cause of death

In 44 of an independent series of 134 cases of pneumoconiosis studied both clinically and at necropsy severe atheromatous lesions affecting a third or more of a major coronary vessel, myocardial infarction, or myocardial fibrosis were found at necropsy In 15 (11%) it contributed to the cause of death The condition was present in 37% of the 54 persons in the age group 55 64 and in 50% of the 26 persons aged 65 or more (table II)

Review of the clinical records suggested that an ante-mortem diagnosis was possible in 48% of these cases—i e, 16% of the total In the remaining 52% coronary heart disease was a silent condition (cf Boas and Boas 1949) This high prevalence of silent cases may have been due to the difficulty of diagnosing coronary heart disease in the presence of pulmonary disease Three factors—the character of chest pain, the presence of left ventricular enlargement without other cause, and the electrocardiographic findings—were therefore re examined with a view to improving the accuracy of diagnosis in these circumstances (Thomas 1956a) The findings suggested that

insufficient by themselves for the diagnosis of cardiac ischæmia in the presence of left ventricular hypertrophy *due to coexisting hypertension.* Left ventricular hypertrophy has been diagnosed by the criteria of Wilson et al. (1947) and of Sokolow and Lyon (1949).

Left ventricular enlargement and considerable left axis deviation, in the presence of massive pulmonary fibrosis calculated to produce a vertical heart with right preponderance, was ascribed to coronary heart disease where no other reason for enlargement of the left heart could be found.

RESULTS *

2 of the 55 men selected had died since the enumeration in the previous summer, one of pernicious anæmia and the other of heart failure and pneumoconiosis; they did not come to necropsy. 2 men had left the district, and 4 declined to participate; these 8 lapses had a mean age of 61·1 (range 56–64).

47 men, who form 85% of the original random sample (92% of those still living in the area), were examined (see table III).

Coronary Heart disease

18 cases of coronary heart disease were found, giving a prevalence of 38%. The mean age of these men (61·1), and the mean number of years they had worked underground (27, range 2–48) and at the coal face (12, range 0–37) did not differ significantly from those of the remaining men in the sample (60·6, 30, range 7–51 and 18, range 0–44, respectively).

Of the 18 men 10 considered themselves fit and were actively employed at the time of investigation. Of the remaining 8, 3 (nos. 3, 5, and 15) had taken up light jobs after episodes of heart failure or acute myocardial infarction, and 5 were out of work, of whom 2 (nos. 2 and 13) were in early heart failure, 2 (nos. 4 and 16) were convalescing from attacks of myocardial infarction, and 1 (no. 7) had lost an arm in an accident and was unemployed on this account. There was no material difference in mean age or mean systolic blood-pressure between the 7 men with and 11 men without disabling cardiac insufficiency. The disabled group was on average 14 lb. heavier, but the difference was not statistically significant (P≃0·3).

14 of the 18 cases of coronary heart disease were tentatively diagnosed as such by clinical and radiographic examination before recourse to electrocardiography. In 11 a provisional diagnosis was made.

4 of the 11 cases (nos. 4, 5, 15, and 16) gave a history indicating myocardial infarction; these and 4 others (nos. 1, 11, 13, and 14) gave a history of pain on effort typical of myocardial ischæmia. 1 man without pain (no. 2) had clinical heart block and left ventricular enlargement. 2 other men (nos. 17 and 18) *had radiographic evidence of left ventricular enlargement* for which no other cause could be found.

---

* An appendix describing findings in the 24 cases referred to here by number may be had from the Pneumoconiosis Research Unit.

TABLE III—AGE, WEIGHT, BLOOD-PRESSURE, DIAGNOSIS, AND PHYSIOLOGICAL FINDINGS

No	Year of birth	Wt (lb.)	Clinical grade of dyspnœa	Blood-pressure (mm. M V V, maximum ventilatory volume.
P H D, pulmonary heart disease.
P M F, progressive massive fibrosis of pneumoconiosis.
S, heavy smoker at some time (see text).

few weeks the diastolic pressure fell to 100–110 mm Hg, ut it rose later to 120 mm Hg

Nervous and tense patients have all experienced a ranquillising effect from serpasil, and in all cases the ulse-rate has decreased There seems to have been no ostural effect on the blood-pressure in patients taking erpasil only The interval between the start of treatment and significant improvement has been very varied—from two to twelve weeks—but it has usually been less than four weeks

We have been quite unable to forecast the probable effect on any patient before treatment was started, and are unable to correlate success or otherwise with ætiology, length of history, age, sex, or temperament Of the 17 patients who had good results with serpasil only, 3 had renal hypertension, and 1 had malignant essential hypertension Of the 9 who showed good results with serpasil added to pentolinium or hexamethonium, 1 had renal hypertension and 4 had malignant hypertension, 1 other had polyarteritis nodosa

Side effects were common, drowsiness and nasal stuffiness were experienced by over half the patients Diarrhœa occurred in 4 cases An unusual feature in 3 female patients was lactation

One is an unmarried woman, aged 29, who has never been pregnant Her breasts have enlarged and lactation has continued intermittently for six months, milk coming from both breasts at intervals of several days, unrelated to menstruation The quantity has not been recorded, but a 10 ml sample was obtained without difficulty, and was found to have the following composition total protein 2 8%, total fat 3 7%, lactose 6 5%, calcium 31 mg per 100 ml, phosphatase 11 5 King Armstrong units per 100 ml The protein content is higher than average but all figures are within accepted standards for normal human milk Microscopically the usual fat globules of various sizes were clearly visible This patient lives about 70 miles from Manchester and because of the difficulty of personally supervising her treatment she is not included in this series She has renal hypertension, the result of chronic type 1 nephritis, and her initial response to serpasil was excellent

The 2nd case is in a woman, aged 49, in whom swelling and tenderness of the breasts with secretion of small quantities of fluid occurred about a week before each of four menstrual periods The condition subsided and her periods ceased, presumably because of a natural menopause She has seven children

The 3rd case is in a woman, aged 38, who had continuous secretion for four weeks, unrelated to menstruation This ceased spontaneously although serpasil was continued She has one child, aged 10

We have had to stop treatment in 10 cases because of depression, one of these patients required admission for electroconvulsion therapy in a mental hospital, and one, we regret to report, committed suicide In nearly all these cases there was a history of previous instability One patient who was having injections of pentolinium and who was given serpasil developed moderately severe anginal pain at lunch time each day

We had had to reduce her dose of pentolinium gradually on account of hypotensive symptoms, and although she showed none of these symptoms at the time when angina developed, it was presumably caused by hypotension, as her blood pressure was found to drop from 190/130 mm Hg to 105/60 mm Hg on standing at midday Possibly she did not experience the usual symptoms of hypotension because she was seated on each occasion This patient's dosage of pentolinium had to be reduced by one third after the addition of serpasil

Illustrative cases —Figs 2 and 3 show the fall in blood-pressure in 2 successful cases, one patient receiving alternately serpasil and inert tablets, and the other patient having serpasil added to pentolinium treatment

Conclusions

As a result of this study of 54 patients treated with reserpine (serpasil), we conclude that the drug has a significant, and sometimes a profound, hypotensive effect in at least 40% of cases of severe hypertension, but it is obviously wasteful and useless to continue its administration in cases which do not respond

We have not been able to find any means by which the response may be foretold

In the most severe cases reserpine is probably better used in combination with other drugs

Reserpine is a dangerous drug The immediate side effects are not usually dramatic, but it may cause severe depression, and this led to suicide in one of our cases

Administration of reserpine to women occasionally results in lactation

We are grateful to Mr H Varley, biochemist to the Royal Infirmary, Manchester, for the milk analysis, to Mr J B Lloyd, chief pharmacist, and his staff for their coöperation in this investigation, and to Ciba Laboratories Ltd. for supplying inert tablets simulating 'Serpasil'

PROGRESSIVE EXOPHTHALMOS TREATED BY ORBITAL DECOMPRESSION

G F Rowbotham
B Sc Manc, F R C S
REGIONAL CONSULTANT IN NEUROLOGICAL SURGERY

P R R Clarke
M B Lond, F R C S
SENIOR REGISTRAR, DEPARTMENT OF NEUROLOGICAL SURGERY
GENERAL HOSPITAL, NEWCASTLE UPON TYNE

We describe here 30 cases of progressive exophthalmos treated by a type of orbital decompression not previously reported Other methods of treatment have lately been fully discussed elsewhere—notably by Naffziger (1954) and by Dobyns (1950)

Material

All 30 patients were treated in the department of neurological surgery of the General Hospital, Newcastle upon Tyne In 15 cases the disorder was unassociated with disease elsewhere in the body, and in the other 15 cases the patients had been treated for thyrotoxicosis

Progressive exophthalmos unassociated with disease elsewhere —The ages of the 15 patients (10 men, 5 women) in this group ranged from 28 to 71 years The disorder was unilateral in 12 cases and bilateral in 3 cases, and in each of these 3 cases bilateral decompression was carried out

Progressive exophthalmos associated with thyrotoxicosis —The ages of the 15 patients (7 men, 8 women) in this group ranged from 28 to 67 years In each of the 15 cases the disorder was bilateral, and in 9 bilateral decompression was carried out The disorder was related to previous treatment as follows first appeared after thyroidectomy, 3, increased after thyroidectomy, 6, first appeared after thiouracil, 1, increased after thiouracil, 3, improved after thiouracil, 1, increased after radioactive iodine, 1

All patients complained of pain in the orbit, this varied from a feeling of "grittiness" and irritation in the milder cases to very severe discomfort in the most severe In every case there was some ophthalmoplegia, but in 6 this was severe and was associated with diplopia. Corneal ulceration necessitated bilateral tarsorrhaphy in 2 cases and unilateral tarsorrhaphy in 3 cases

The Operation

After the scalp has been shaved and prepared the patient is placed on the operating table in the supine position The

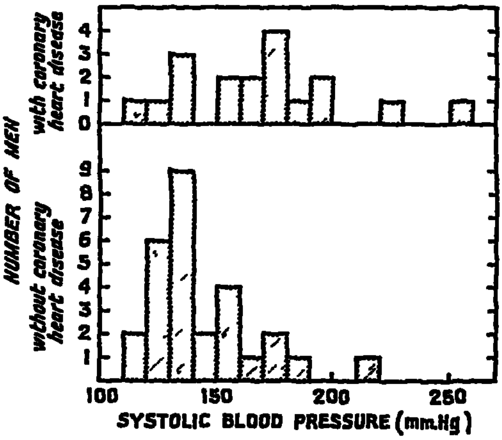

Fig 2—Distributions of systolic blood-pressure in men with and without coronary heart-disease

Of the 3 remaining men in whom coronary heart-disease was suspected on clinical or radiographic grounds 1 (no 9) had left ventricular enlargement and developed a paroxysm of auricular tachycardia on exercise, 1 (no 3) was in heart failure of recent origin and had radiographic evidence of left ventricular enlargement in the presence of massive pulmonary fibrosis, and 1 (no 1) had a moderate apical systolic murmur

4 men (nos 6, 7, 8, and 12) had no symptoms and no clinical signs of heart disease 1 of these men (no 6) did give a history of six months' illness two years previously, which may have been cardiac

Electrocardiograms proved, in our opinion, coronary heart disease in 17 men and strongly suggested it in 1 other (no 18), who had complicated pneumoconiosis with left ventricular enlargement but normal blood pressure

The commonest electrocardiographic pattern was that of left axis deviation with depression or deformity of the ST segment in leads I, II, VL, V_4, and V_6, with flat or inverted T waves in some of these leads

The electrocardiographic identification of possible coronary heart disease in the presence of gross signs of left ventricular hypertrophy presented a diagnostic problem in the case of 1 man (no 13) who had severe angina of effort Here a steep downward inclination of the ST segment in V_4 with no T wave was considered to clinch the diagnosis (cf Holzmann 1952)

In another case with pain on effort typical of cardiac ischæmia (no 10) some aortic stenosis was also present The blood pressure was 112/50 mm Hg, peripheral pulsation was good, and the electrocardiogram showed signs of cardiac ischæmia without left ventricular hypertrophy Coronary heart disease was considered the principal lesion This man died ten months after the survey, and necropsy revealed coronary thrombosis associated with severe atherosclerosis

The detailed electrocardiographic findings are shown in fig 1

Atherosclerosis

Generalised atherosclerosis of considerable degree was present in 4 of the 18 men who had coronary heart disease (nos 10, 13, 16, and 17) and in 4 other men who did not show electrocardiographic changes of myocardial ischæmia

In addition to greatly thickened and tortuous peripheral arteries, unfolded aorta, and irregular narrowing of the retinal arteries, 1 of these 4 men (no 19) had intermittent claudication and evidence of a previous cerebral thrombosis, 1 (no 20), who also had massive pulmonary fibrosis was orthopnœic had attacks of giddiness, and was in early congestive heart-failure, 1 (no 21) was hypertensive (blood-pressure 210/95 mm Hg) but had little subjective disability, and 1 (no 24) had pulmonary heart-disease

Coronary Heart disease, Blood pressure, and Body w

The mean blood-pressure recorded lying down w 150 0/84 1 mm Hg for all the men (average age 6 This agrees well with the values of 145/85 and 14 mm Hg reported for men of the same mean age b Hamilton et al (1954) and Miall and Oldham (195

The mean blood-pressure was 165 8/89 4 mm Hg f the 18 men with coronary heart disease and 139 mm Hg for the remainder The two groups were exactly comparable ages, and the 26 4 and 8 7 mm H mean differences in systolic and diastolic blood pressu are statistically significant (0 01>P>0 001 and 0 05> P>0 02 respectively) (fig 2)

The average body-weight of the men with corona heart-disease was 156 9 lb (range 120–220 lb) and f those without 133 8 lb (range 102–173 lb) The variatio in body-weight was significantly greater in the men with coronary heart disease (P<0 02) Thus the significan of the higher average is uncertain, though it appears reach the 5% level (fig 3) Coronary heart disease w present in 13 of the 22 men with systolic pressures 150 mm Hg or above, and in the 5 men whose bod weight exceeded 13 st, which was 40 lb more than mean weight for the whole group The systolic blo pressure ranged from 158 to 180 mm Hg in the men, but this is likely to be an overestimate of the t pressures because no allowance was made for arm g (cf Ragan and Bordley 1941)

Pulmonary Heart disease

Pulmonary heart disease was diagnosed on the elect cardiographic findings in 3 men 1 (no 22), who h worked underground for 28 years, had progressive m sive fibrosis and an unproductive winter cough with acute exacerbation The 2 others, neither of wh had pneumoconiosis, gave a history typical of chro bronchitis, one of these (no 24) had worked 11 ye as a collier and the other (no 23) 44 years as a repai underground

Ballistocardiography

The average amplitude of the I–J wave of the ballist cardiogram was obtained over the first 5–6 cardiac cycl after the start of breath-holding with the chest the inspiratory position Satisfactory measuremen were obtained in all except 1 man (no 2) with coron heart disease and heart-block, whose tracings were ve abnormal The mean value for the ballistic impulse w 13 5 (range 30–4) arbitrary units for the cases w coronary or pulmonary heart disease and 16 3 (ran 29–8) units for the remainder This difference is statistically significant (0 10<P<0 20) If, however, men with significant associated pulmonary disease excluded, the mean ballistic impulse of those remaini with coronary heart disease was 12 9 (range 4–25) un compared with 17 7 (range 8–29) units in those witho This difference, which is significant at the 5% level

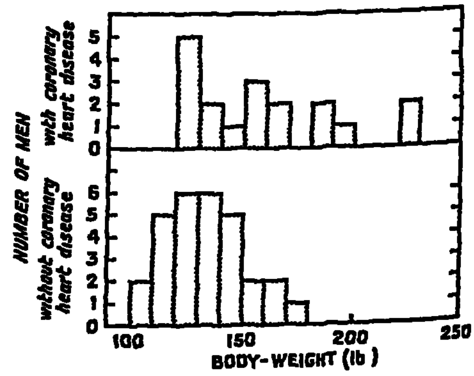

Fig 3—Distribution of body weight in men with and without coron heart-disease.

robably an increase in orbital fat, that the muscles are rge and infiltrated by lymphocytes, and that in the later tages in untreated cases the muscles may be replaced by brous tissue

Discussion

-Etiology

In some of our cases treatment of thyrotoxicosis had een followed by onset or exacerbation of exophthalmos The *general consensus of opinion* seems to be that an nterior-pituitary-gland hormone is responsible for the evelopment of the condition Experimentally this has een shown to be the case in many animals, Friedgood, or example, has demonstrated that in guineapigs nterior-pituitary extract will produce thyrotoxicosis and xophthalmos initially, and that after two to three weeks, lthough the thyrotoxicosis wanes, the exophthalmos continues to increase (Friedgood 1934) Dobyns and Wilson (1954) have demonstrated the presence of "exophthalmos-producing substance" in the serum of patients with progressive exophthalmos

-Treatment

All our cases were referred by physicians or ophthalmologists either because they felt that methods of treatment other than orbital decompression were unlikely to help or because other methods had been tried without success The condition is in many cases self-limiting and can be subject to remarkable remissions Our cases, however, were all truly "progressive"

The medical treatment of this disorder consists in measures to inhibit the secretion of thyrotrophic hormone by the pituitary gland Despite the theoretical basis for administration of thyroid gland, results seem to be poor Friedgood (1941) describes them as "notoriously unsatisfactory," and Dobyns (1950) has come to the same conclusion Russell Brain (1952), reviewing 150 cases, stated that 45% were unchanged by medical treatment and 15% were exacerbated Œstrogens and *p*-hydroxypropiophenone (H365) have also been tried (Okie et al 1952) The effects of cortisone and corticotrophin in the control of progressive exophthalmos appear to be disappointing (Medical Research Council 1955)

Radiotherapy applied to the pituitary gland is credited with some successes (Dobyns 1950), but in our opinion it is not justifiable to submit the pituitary gland and neighbouring structures, in particular the hypothalamus, to the effects of X-irradiation for this condition Orbital irradiation seems to be more successful in the non-thyrotoxic group (Jones 1951)

Laurent and Scopes (1955) have reported 1 case treated successfully by subconjunctival injection of hyaluronidase This method clearly needs further trial

The discovery of some reliable method of endocrine control may not be long delayed, but at present it seems that the only method of treatment that can be relied on to give consistently good results is adequate surgical decompression Most surgeons still use the operation described by Naffziger in 1931

Thus entails raising a coronal scalp flap and one or two frontal bone flaps, after elevation of the dura mater, the roof and lateral wall of the affected orbit or orbits are removed from above This operation has been extended by Poppen (1950) to include removal of the walls of the frontal and ethmoidal air sinuses

Dickson Wright (1948) has described a direct approach to the orbit, using an incision across the forehead and *temporal fossa*

We believe that the operation here described fulfils the need for adequate decompression while observing cosmetic considerations, furthermore, it is simple to perform

The indications for operation that we follow are severe exophthalmos unresponsive to medical treatment, threatened or actual corneal damage, pain, chemosis, papillœdema, and ophthalmoplegia causing diplopia

Because the results of decompression have proved so satisfactory, we enter a plea that patients should be referred before the cornea is damaged and before irreversible changes have taken place in the optic discs, extrinsic ocular muscles, or conjunctiva

Summary

An operation for orbital decompression in patients with progressive exophthalmos is described, and the results in 30 consecutive cases are reported The operation and pathological findings are analysed

We wish to thank our medical and ophthalmological colleagues for referring the patients to us, Mr J M L Howat for his help in the management of our patients, and Miss M E Bousfield for assistance

INTERSTITIAL EMPHYSEMA, PNEUMOTHORAX, AND "AIR-BLOCK" IN THE NEWBORN

JOHN L EMERY
M D Brist, D C H
PATHOLOGIST, CHILDREN'S HOSPITAL, SHEFFIELD

INTERSTITIAL emphysema of the lung and mediastinum presents in the first few weeks of life in three fairly definite clinical categories

(1) The first group of cases appears to be the direct consequence of violent artificial respiration directly after birth Resuscitative emphysema occurs in asphyxiated infants and is often only a terminal event due to "heroic" attempts to maintain life Such infants are extremely ill from birth

(2) A second and well recognised group occurs in infants who have infection, often staphylococcal, of the respiratory tract In our experience these infants are all over the age of 6 days at the time of death and have various associated pulmonary conditions—e g, "bronchiectasis," pneumatoceles, and recurrent tension pneumothorax

(3) The third group is in several respects quite different from the others Interstitial air arises spontaneously without artificial respiration in infants that have been lusty at birth It occurs within a few hours or days after birth and is often rapidly fatal

This last group is the subject of this study The purpose of this paper is to demonstrate the incidence, the clinical features, and the apparent cause of this condition

Present Study

14 cases of interstitial emphysema of the lung and mediastinum, with death apparently due to air-block, were seen in the necropsies that I have done in the last five years Until 1954 the necropsies were almost entirely from a highly selected group of teaching hospital admissions, so the numbers gave little idea of the over-all prevalence of the disease Since 1954 the infants coming to necropsy have comprised the majority of deaths in Sheffield in this age group Thus the recent cases provide a guide to prevalence

Prevalence

Of the last 100 necropsies that I have done in 1954–55 in Sheffield on infants dying within 7 days of birth 48

STRESS FRACTURE OF RIBS IN PREGNANCY

DAVID SAVAGE
M B Lond , F R C S , M R C O G
REGISTRAR, CHARING CROSS HOSPITAL, LONDON

FRACTURE of a rib due to coughing was first described by Graves (1833) Since then 144 cases have been reported (Malgaine 1859, Gurlt 1862, Tunis 1890, Bähr 1894, Seilin 1917, Popischill 1921, Kleiner 1924, Halliwell 1929) Webb and Gilbert (1923), Palfrey (1924), and Swineford and McKinnon (1945) emphasised that these fractures might easily be missed and that they were far commoner than was generally supposed The great majority of reported cases were in patients with pulmonary tuberculosis (Oechsli 1936, Richardson 1936, Sakka 1938, Cohen 1949), but Mitchell (1951) reported that of 720 non tuberculous patients referred to him on account of chest symptoms 106 had pleural pain, and of these 14 had stress fractures of ribs

There are 13 recorded cases of stress fracture of the ribs in pregnancy In only 1 of these cases did the fracture occur in labour, and in this instance the fracture was due, not to the patient's expulsion efforts, but to a fit of coughing (Ahern 1894) In all cases the fracture occurred in the last months of pregnancy and in the present series all had fractures after the 36th week

In the 4 cases described by Paulley et al (1949) serum calcium and phosphorus levels were within normal limits

Case-reports

The 3 cases reported here attended Queen Charlotte's Maternity Hospital in the first two months of 1953

Case 14 —Multigravida (one previous normal pregnancy), aged 30 years At the 37th week of pregnancy the patient had an irritating, unproductive cough During a particul severe bout of coughing she felt a sudden snap in the low part of her left chest, and this pain persisted and was ag vated by coughing Radiographic examination revealed a transverse fracture of the shaft of the 11th rib at the junct of its middle and outer thirds

Case 15 —Primigravida, aged 33 years At the 42nd week of pregnancy the patient was sitting in a chair when she tur and coughed She felt a click in the right side of her ch and this was followed by a persistent pain Radiograph examination showed a transverse fracture of the shaft of th 11th rib at the junction of its middle and outer third

Case 16 —Primigravida, aged 30 years At the 36th week pregnancy a pain developed gradually in the left side of th patient's chest This was not initiated by coughing but wa aggravated by coughing and deep breathing The p gradually subsided in the following 3 weeks At the 3 week of pregnancy the patient felt a similar pain on the ri side, and again this was not initiated by coughing Rad graphic examination revealed a fracture of the shaft of 6th right rib, with minimal disalignment in the ant axillary line, and, immediately below it, a greenstick fract of the 7th right rib On the left side there were fracture *longer standing involving the left 6th and 7th ribs in* anterior axillary line, with slight callus formation

Discussion

More than a century ago Hilton (1852) taught th a rib fracture might give rise to pain indistinguishabl from that of pleurisy This erroneous diagnosi strengthened by the absence of displacement of fragments on physical or radiographic examinati

coming from the nose. She called the midwife, who called he doctor, who ordered its immediate removal to hospital. The infant died in the ambulance aged about 14 hours.

Case 5.—The following is the letter that the family doctor sent with the child when the child was brought in for necropsy. "The child (a boy) was postmature and born at 4 P.M. The confinement was normal. There was a lot of meconium in the amniotic fluid. He recovered reasonably quickly and cried normally. Birth weight $8^1/_2$ lb. He appeared well at 10 A.M. today, but at 11 A.M. the midwife noticed that he was a little cyanosed. This cyanosis was when he cried. I was called to see him at noon, and again at 12.45 P.M., when arrangements were made to admit the child to the Children's Hospital." The infant died before it could be admitted, at about 1.20 P.M., aged $21^1/_2$ hours.

These histories illustrate the features of the whole series. All the infants were mature or postmature. In 7 there was a spontaneous remark on the presence of an abnormal amount of mucus or meconium on the face of the infant. Only 1 of the infants had "asphyxia" at birth. All cried spontaneously and did not require artificial respiration. 5 of the cases came to me by way of the coroner but many of the others could well have come the same way but for the enlightened outlook of the local coroner.

Pneumothorax was present in 11 of 13 in this series in whom the chest was opened under saline—on the left side in 10, and on both sides in 5.

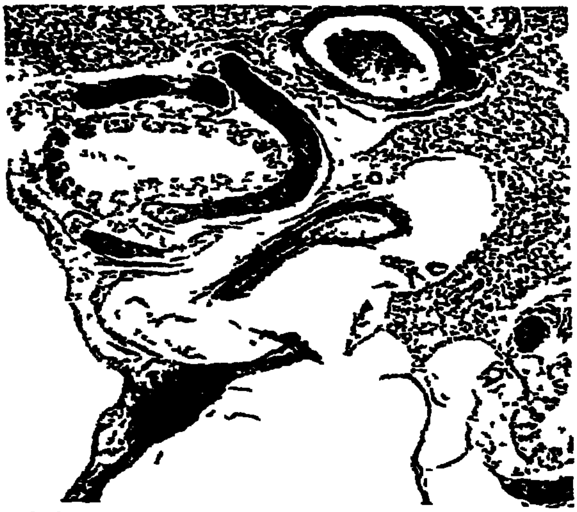

Fig 3—Low-power view of lung showing interstitial air compressing a vessel near a bronchus.

The ages of the infants at death were 4–49 hours. 2 had shown no abnormal symptoms and were simply found dead. The others had symptoms lasting from about half an hour to twenty-four hours consisting either of cyanosis or of a notable alteration in the character of respiration.

Pathology

The trachea and main bronchi in these cases did not appear to be obstructed.

The air vesicles in the interstitial tissue of the lung were larger as the hilum was approached, those at the hilum and junction of the lung and mediastinum often forming a sort of tense collar round the root of the lung (fig 1).

After fixation, the presence of air surrounding the vessels in their sheaths was usually obvious to the naked eye (fig 2) and more easily seen in sections (fig 3).

Microscopy revealed the presence of masses of mucus usually containing either whorled plugs of keratinised squames (fig 4) or small sheets of similar squames in the smaller bronchi and bronchioles. These keratinised non-nucleated squames are the cells found in vernix. Beyond many such masses of mucus small areas of dilated alveoli were often found (fig 5), and in some cases actual points of rupture of such acini into the connective tissue could be seen (fig 6).

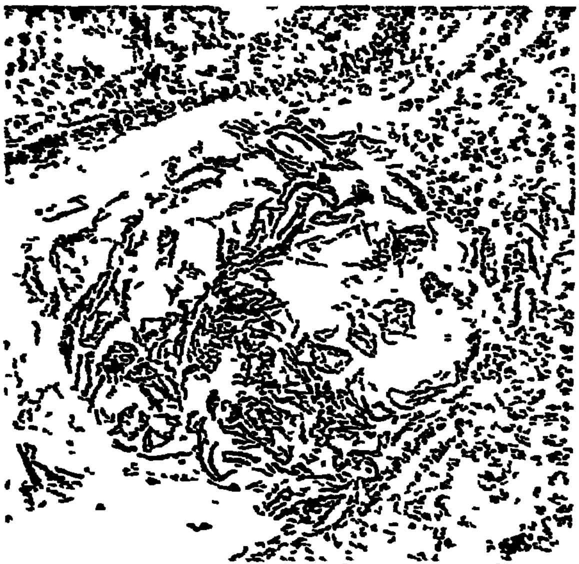

Fig 4—Bronchiole obstructed by non-nucleated keratinised squames—i.e., a mass of vernix.

No air-embolism was seen in this series of infants, and in no case was pneumonia or infection of the respiratory tract found.

None of these infants showed any developmental abnormality of the respiratory tract and mediastinum, and no pathological lesions were found outside the chest. The right hearts in the infants appeared to be unusually distended, but no significant enlargement of the liver was noted.

The immediate cause of death in all these infants was air in the pleural cavity and mediastinum with apparent compression of the vessels at the roots of the lungs, producing "air-block." The interstitial emphysema in all the cases appeared to be due to mucus, with amniotic debris and vernix, causing differing degrees of obstruction in the smaller air-passages of the lungs.

DISCUSSION

Prevalence

The recorded incidence of interstitial air in the chest in normal infants varies. Davis and Stevens (1930)

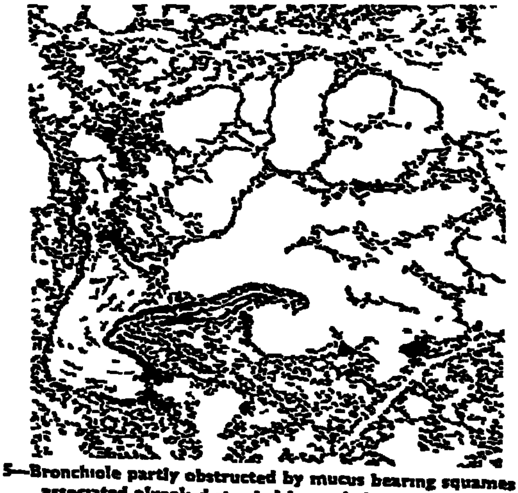

Fig 5—Bronchiole partly obstructed by mucus bearing squames, and associated alveoli distended beyond the obstruction.

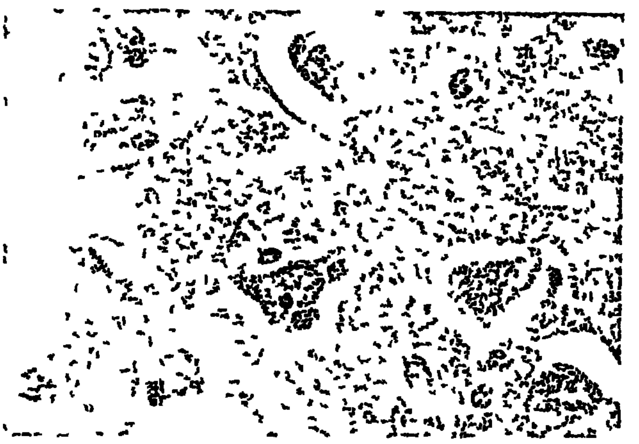

Section of brain containing Negri bodies (×275)

for an hour or two He was seen again at 6 P M, when he was sitting up in bed eating an orange with some difficulty He complained of some tingling in the right arm for the last three or four days, and there was wasting of the interossei in the first and fourth spaces of the right hand Both arms appeared wasted compared to their condition a year ago, and the grip although equal, was not that expected in a man of his occupation Tuinal gr 3 was given for the night At 9 45 P M his father in law telephoned to say that the patient was as bad as ever, wandering in speech, restless, and frightening his wife

On re examination he was restless, with a tendency to dyspnœa He became calm when questioned, and admitted that he had been bitten by his dog while in Pakistan, where rabies is endemic It was only a scratch on his right forearm, and the dog died next day with fits His mates said it died of distemper Pressed to remember when he was bitten he said finally that it must have been at the end of February or the beginning of March Rabies was diagnosed and the patient was admitted to hospital that night

On admission there was slight weakness of his right arm, and the circumference of the right forearm was $^1/_2$ inch less than that of the left forearm His temperature was 100 2°F, pulse rate 120, and respirations 22 a minute He refused a glass of water vigorously but was not at all upset when the water taps were turned on Rabies was provisionally diagnosed, and intramuscular penicillin 500,000 units and phenobarbitone gr 3 were given

Investigations —On May 10 chest radiography showed that the lung fields were clear A blood count showed Hb 120%, white cells 22,100 per c mm (polymorphs 79%, lymphocytes 15%, monocytes 6%) No tubercle bacilli were seen in the sputum Lumbar puncture was not done

Treatment and Course —Intramuscular phenobarbitone gr 3 was given six-hourly The patient's general condition seemed a little improved, and the attacks of breathlessness, in which he threw back his head, jerked an arm, and complained that he could not breathe, decreased He stated that "belching wind" warded off attacks He refused fluids vigorously On May 11 he ate sections of orange, had one or two teaspoonfuls of tea, and was given a rectal saline drip Rhonchi and râles were present at both bases He was very loquacious A barium swallow was attempted, but he rejected the barium mixture His temperature was 99°F On May 12 he was mentally confused and still had spasms in which he complained that he could not breathe His temperature was 101°F At 5 P M he became more disoriented and restless He was given intramuscular paraldehyde 8 ml At 10 P M he became much more restless and was given another dose of intramuscular paraldehyde 8 ml His temperature had risen to 102°F At 1 20 A M on May 13 he became irrational, noisy, and abusive, and was given intramuscular paraldehyde 10 ml and intramuscular chlorpromazine 50 mg with effect The rectal drip was continued His general condition deteriorated, and he died at 5 A M

Necropsy Findings —Good physique, no scar on right forearm or elsewhere *Heart* myocardium pale and cloudy, a few petechial hæmorrhages beneath the visceral pericardium on the posterior aspect of the left ventricle *Larynx, trachea,* and *bronchi* contained much mucopus *Lungs* much co gestion *Mouth, pharynx,* and *œsophagus* normal L congested and swollen *Brain* congested, with scat petechial hæmorrhages *Spinal cord* not examined Portio of the right hippocampus and the right submaxillary g were fixed in formol saline solution, and other pieces w frozen in 50% glycerin The Group Laboratory report that sections of brain showed the perivascular lympho c collections of encephalitis with, in the hippocampus n the Negri bodies of rabies (see figure) The Central Pu Health Laboratory, Colindale, reported that sections of bra direct smear, Seller's stain, contained scanty Negri bodi The specimen fixed in formol saline solution appeared to b mainly white cortex, and sections of it showed no obvi abnormality The virus of rabies was isolated by inoculati of mice No Negri bodies were seen in the salivary gla but the rabies virus was isolated by inoculation of mice

Contacts

The case was notified to the Medical Officer of Heal the day after admission to hospital On his advice, a immediately the diagnosis was confirmed, the patient wife and child were given a light course of anti rab vaccine, because there is believed to be a slight risk infection by kissing The vaccine was supplied by th Lister Institute Daily injections of 2–4 ml into th abdominal wall were given for fifteen days, and n reaction was suffered by either patient Nine mont after contact both are well

One dog and three cats, pets in the household, we destroyed, two dogs were put into quarantine, and a now freed.

Discussion

Rabies is a disease of dogs, jackals, wolves, a vampire bats in Trinidad, transmitted to other mammal including man, by bites from infected animals T disease is ordinarily non existent in the United Kingdo having been eradicated originally by muzzling orders a subsequently by strict quarantine of dogs entering t country The cause is a neurotropic virus with a incubation period of from ten days to a year—usual not more than five months, and commonly from one t three months This variation is said to depend on bot the situation of the bite and the dose of virus inoculated A fresh abrasion licked by a rabid animal can b dangerous, and intact mucosa can transmit rabies

The virus spreads along the nerves from the site inoculation, hence bites on the face and hands, w rich in nerves and usually uncovered, are particula dangerous From the spinal cord the virus spreads bo distally and to the higher centres, hence all the nerv tissue in the body may be infected Infection reac the salivary glands along the nerves and not thro the blood-vessels

The necropsy findings are those of encephalitis, a the only typical laboratory findings are Negri bodies the nervous tissue on section and reproduction of t disease in animals by inoculation of infected tissue

The established disease falls into three phases

(1) The prodromal state, lasting from two to three da with malaise, fever, irritability, loss of appetite, and pa irritation at the site of the bite

(2) The stage of excitement, lasting from two to three da with difficulty in swallowing fluids, alternate rational a irrational periods, severe muscular spasm particularly affect the muscles of the pharynx and larynx, and an undue s ceptibility to stimuli—e g, noise and draughts Heavin on the chest, difficulty in breathing, and hydrophobia manifestations of the muscular spasm

(3) The paralytic stage, lasting about twenty four hour less, leads to death The patient commonly remains clea his mind until near the end

The paralytic type of disease ("dumb rabies") is ra There is no excitement, and the course is usually lon than that of the "furious" type follows infection of the lung in the newborn" Much misconception has been due to the attempt to consider immature, mature, and postmature infants as a single entity

DeCosta (1940) distinguished two types of pneumothorax in the newborn One, "pneumothorax abrupta," occurred at birth in debilitated infants and had a 42% mortality, and a second, "pneumothorax lenta," occurred hours or days after birth Of the 34 infants with the latter type of pneumothorax that he could find reported 2 had received artificial respiration Though he did consider that mucus, vernix, and coughing were important, he discussed also congenital deformity of the lung, trauma, and infection

Rothman (1937) described 2 cases in this country and considered that enlargement of the thymus, collapse of the epiglottis, and congenital pulmonary defects were of more importance than obstruction of the respiratory tract by inhaled material The reason for his inclusion of multiple defects appears to be that many cases of inspiratory obstruction accompanied by the most laboured inspiratory efforts do not produce emphysema or pneumothorax This view is based upon a misconception that interstitial emphysema is due to excessive inspiratory efforts, it not being generally realised that it is only by increased expiratory effort that air can be spontaneously expelled into the connective tissue

Prevention

The shortness of histories and the present poorly studied symptoms of the newborn suggest that interstitial emphysema will remain either a post mortem or radiological diagnosis for a little while Furthermore, the bronchi and bronchioles that are obstructed and responsible for the interstitial emphysema are, by the time the lesion has developed, too small to permit surgical aspiration Thus the clinical approach must be entirely towards prevention

Since amniotic debris and mucus were inhaled in all the cases, the clinical problem lies in dealing with a child showing meconium or excess mucus on the face and in the upper respiratory tract

There is a tendency to think that careful and complete removal of mucus is of major importance only in a weak immature infant, yet it seems that mucus can be, if anything, more dangerous in a mature child who cried lustily soon after birth It is possible that respiratory stimulation and enthusiastic methods to make a child give a "good yell" as soon as possible after birth are sometimes misplaced A mature child can probably withstand small areas of atelectasis better than it can interstitial emphysema

Summary

Clinical and pathological data are presented of 14 infants who died as a result of spontaneous interstitial emphysema of the lung and mediastinum within the first 6 days after birth

This condition appears to be due to excessive expiratory effort following inhalation of meconium or mucus

In a recent necropsy series this condition was apparently the commonest single cause of death in normally formed mature and postmature infants

It is a pleasure to acknowledge the coöperation of Dr T Colver Dr L P DeAbrew, Dr K F Garside, Dr R R Gordon, Prof R S Illingworth, Dr E Miller, Dr A J N Warrack, and Dr J D Young

TREATMENT OF NEPHROSIS WITH PREDNISOLONE

GAVIN C ARNEIL
M D Glasg, M R C P F R F P S, D C H
LECTURER IN CHILD HEALTH IN THE UNIVERSITY OF GLASGOW,
PÆDIATRICIAN, ROYAL HOSPITAL FOR SICK CHILDREN,
GLASGOW

THE treatment of nephrosis is unsatisfactory Cation-exchange resins (McChesney et al 1951), artificial infection with malaria (Gairdner and Shute 1955), and hormones such as cortisone and corticotrophin (Arneil and Wilson 1952, 1953) have proved of limited value All these treatments can provoke diuresis on occasion but fail to reduce the albuminuria consistently The results of cortisone and corticotrophin treatment are confused by the retention of sodium during treatment and the loss of sodium when the treatment is stopped, since such electrolyte fluctuations materially alter the degree of œdema

With the advent of 'Deltacortril' (prednisolone) a synthetic hormone with a cortisone like action but little or no sodium-retaining property (Bunim et al 1955), it seemed possible that a potentially useful form of treatment was to hand Accordingly this substance was used to treat 4 œdematous patients with nephrosis at this hospital

Methods and Material

Albuminuria—The urine passed in every twenty four hours was collected and the absolute loss of albumin calculated by the Esbach method

Serum proteins—Total serum-proteins were estimated, and electrophoretic fractionation was done by a modification of the method described by Cremer and Tiselius (1950) Readings were made with a scanner of the 'EEL' type

Blood cholesterol Level—This was estimated by the method described by Dutton (1932)

Erythrocyte sedimentation Rate (E S R)—The standard Wintrobe method was used

Diet—The patients were allowed the normal ward diet but with the sodium content restricted to less than 2 g daily No additional potassium was given

Details of the 4 patients are given in table I The history, clinical findings and biochemistry (table II) were typical of nephrosis in each case

Results

Within six days of the start of treatment the albuminuria decreased strikingly in all 4 cases The daily loss of albumin decreased from 1–4 g to less than 0 25 g in each patient two weeks after the start of treatment Albuminuria disappeared completely in cases 1, 3, and 4 but reappeared (for a few days only) in case 3 six weeks after treatment had stopped The relationship of the alteration in albuminuria to the start of treatment and to the onset of diuresis for the 3 cases in which complete records were obtained is shown in fig 1 In all 4 patients diuresis began within eight days of the start of treatment and lasted from six to eight days During diuresis these nephrotics lost fluid amounting to 26–31% of their non-œdematous body-weight While œdematous they had seemed plump and well nourished, but this sudden fluid loss revealed the underlying wasting All 4 patients

Recent work indicates that intestinal bacteria can affect the absorption of iron Stern et al [18,19] say that rabbits given oxytetracycline (terramycin) and penicillin absorbed no iron, but absorption was restored by adding *Escherichia coli* or enterococci to the diet Subrahmanyan et al [20] state that in man the extent to which phytates are broken down and their phosphorus is made available depends on a number of factors, the most important of which are intestinal bacteria and the calcium content of the diet

Megaloblastic anæmias in the tropics and subtropics are related to the diet [4,5] Some types of diet affect the ecological balance of the intestinal flora and upset the synthesis and absorption of essential factors, and the cure of these anæmias by penicillin is due to its destroying competitors for vitamin B_{12} and restoring the bacterial balance in the gut Similarly, imbalance of the intestinal flora caused by unsuitable diet, may be partly responsible for iron-deficiency anæmias

Loss of Iron

The view that the iron of the body is tenaciously held, and that it is mainly regulated by intestinal absorption through the ferritin-apoferritin/mucosal-block mechanism, is being modified Recent work shows that iron balance is maintained partly by controlling dietary iron absorption and partly through losses, and that the latter can contribute materially to the maintenance of iron balance Serum-iron levels are not necessarily an index of iron absorption [21–23]

The main routes by which iron is lost to the body are the bile (very small quantities), the urine (very small quantities), and the skin, saliva, and hair Mitchell and Hamilton [24] and Adams et al [25] estimated that the losses in cell rich sweat are high Stewart et al [26] concluded that they are insignificant, but their work was done on dogs, which have no eccrine sweat-glands and in which cell desquamation is low as in most fur bearing and hair-bearing animals Using radioactive ^{59}Fe, Dubach and her colleagues [27] found in man that the total quantities lost were between 0 5 and 1 0 mg per day Our own estimations have shown that losses by the dermal route (cell-rich plus cell-poor sweat) vary from 0 3 to 2 3 mg per day

The iron intake of the food is generally estimated in Britain and America as about 13–18 mg per day Of this the proportion absorbed is not more than 10% and probably nearer 8% Thus 15–18 mg in the diet would yield to the body not more than 1 5–2 0 mg daily

It will be evident that if (because the diet is unsatisfactory) absorption of iron from the gut is reduced, and (because the climate is hot and humid) loss of iron in the sweat is increased, the body may easily begin to lose more iron *than it gains* With a daily absorption of, say, 0 7–1 4 mg of iron, and a total loss at the lowest estimate of 1 0–1 5 mg (sweat, urine, fæces), an iron deficiency anæmia will sooner or later develop, even though the diet is adequate in iron

In the areas in which we worked malaria was not of much significance, and we did not regard it as an important cause of iron loss The iron liberated from the red cell by the malaria parasite is available for the resynthesis of hæmoglobin and the acute anæmia that sometimes occurs in severe malaria infection will generally respond to antimalarial drugs alone, no iron being required

TREATMENT

Our work in India showed that a large proportion of the microcytic anæmias respond simply to adequate doses of oral iron (20–35 grains of the ferrous salt daily)—even when the amount of iron in the diet is sufficient (It is known that checks to intestinal iron absorption can be overcome by greatly increasing the amount of dietary iron)

Some of these hypochromic microcytic iron deficiency anæmias failed to respond fully to oral iron alone In these cases we found that the total serum proteins were lower than normal, or the serum albumin was lower, or the marrow contained giant stab cells, indicating dyshæmopoiesis Cases with abnormally low serum proteins or serum albumin required protein in some form generally given as skimmed milk, before they made a full hæmatological response Those which failed to respond to iron and protein, and had giant stab cells in the marrow, made a normal recovery if given 5 mg of folic acid daily for one week, and/or 80 µg of vitamin B_{12} In some patients with normal serum-protein levels and no stab cells in the bone-marrow, iron treatment led to a fall in serum-protein level, reversal of the albumin/globulin ratio, and/or the appearance of stab cells

Many other workers have found low serum proteins and/or reversed albumin/globulin ratios in tropical anæmias Mitchell and Hamilton [24] state that dermal losses of nitrogen and even of amino acids can be considerable and that at high humid temperatures nitrogen loss is 5–7 times greater than at "comfortable" temperatures We have no information on this other than the failure of some of our Indian cases to make a complete hæmatological response unless given proteins It is possible that dermal losses of nitrogen may be affecting the synthesis of hæmoglobin

These tropical anæmias in many cases have multiple deficiencies which are not apparent while there is little blood regeneration The increased hæmopoiesis that follows iron treatment makes increased demands on the stores of protein, vitamin B_{12}, and folic acid, hence the fall in serum-proteins that frequently occurs during iron treatment, and/or the appearance of giant stab cells in *the marrow, or other signs of dyshæmopoiesis*

CONCLUSION

Microcytic anæmia is a very common and serious cause of ill health in most tropical and subtropical countries

It is seen in areas where the diet contains a *sufficiency* of iron

Our observations in India and Africa suggest that the two main causes of iron deficiency anæmias in such areas are (1) failure to absorb iron, because of the type of diet, and (2) excessive loss of iron

Even in normal adults on a normal diet, the maintenance of iron balance is more tenuous than has generally been supposed, on an unbalanced diet with excessive losses *the margin of safety* is even less

Iron is not the only substance needed for hæmoglobin synthesis The occurrence of abnormal serum-protein values the failure of some cases to respond to iron alone and the appearance of other deficiencies during iron treatment indicate the complexity *of the problem*

protein levels in nephrosis It seemed likely that little progress would be made in treating nephrosis until some method of diminishing albuminuria could be found Prednisolone seems to have this property, if so, it should be used primarily to attack albuminuria High initial dosage could be used to eliminate albuminuria followed by such dosage as keeps the urine clear thereafter In this way the method of treating nephrosis with prednisolone would parallel the use of cortisone in suppressing the symptoms of disease, such as acute rheumatism Nor does it seem sensible to delay the start of treatment in the hope that the albuminuria will clear up spontaneously If the albuminuria of nephrosis were as painful as the arthritis of acute rheumatism, we would not stand idly by Yet the nephrotic albuminuria is a sign of much graver prognostic significance than the arthritis which obtains urgent admission and immediate treatment

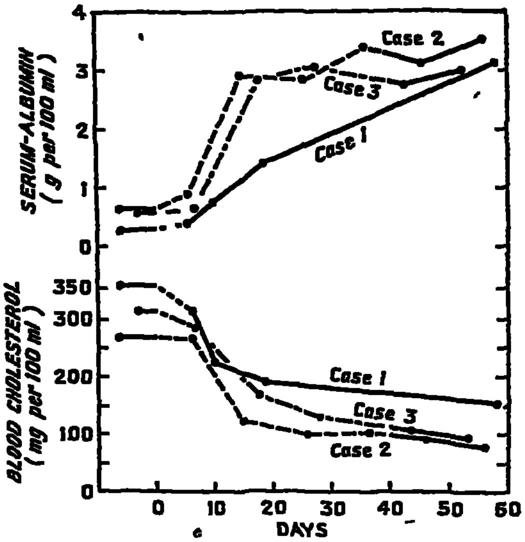

Fig 2—Blood-cholesterol and serum albumin levels in relation to prednisolone treatment.

Summary

Prednisolone treatment of 4 children with nephrosis led to reduction of albuminuria, considerable diuresis, a rise of serum-albumin and gamma globulin levels, a return to normal of the blood cholesterol level and the E S.R , and striking clinical improvement in all 4 cases In 3 patients albuminuria is no longer present, and in the other 1 it is greatly reduced

I wish to thank Prof Stanley Graham and Dr J H Hutchison for allowing me to treat patients in their wards, and Dr H Ellis C Wilson and staff for the biochemical investigations Messrs Pfizer Ltd provided generous supplies of 'Deltacortril'

ADDENDUM

A 5th successive case has now been treated A boy, aged $2^3/_4$ years, with a typical clinical and biochemical picture, began a course of prednisolone (as for cases 2 and 3) six days after the onset of signs Albuminuria lessened on the fourth day and was absent seven days later Diuresis occurred on the seventh day and no œdema has been detected since then Serum-proteins, blood cholesterol, and E S R all returned to normal within the treatment period of forty days

THE ACTIVITY OF DIETHYLDITHIOLISOPHTHALATE ALONE AND COMBINED WITH ISONIAZID IN THE TREATMENT OF MURINE LEPROSY IN THE MOUSE CORNEA

M NAGUIB
M V Sc Cairo
SENIOR LECTURER IN PHARMACOLOGY IN THE EGYPTIAN UNIVERSITY, CAIRO

J M ROBSON
D Sc, M D Leeds, F.R S E
PROFESSOR OF PHARMACOLOGY IN THE UNIVERSITY OF LONDON

THE antituberculous activity of ethyl mercaptan and some of its derivatives was first described by Davies and Driver (1956), who found the most favourable compound to be diethyldithiolisophthalate (compound 15688) In view of the similarity between tubercle bacilli and leprosy bacilli and the fact that certain chemotherapeutic agents which have proved effective against tuberculosis are also of value against leprosy, it seemed possible that ethyl mercaptan compounds might produce a favourable effect on leprosy The present investigation was therefore undertaken to estimate the activity of compound 15688 alone and in combination with isoniazid, and the effect of isoniazid alone was also determined

Methods

The chemotherapeutic activity of the drug was investigated by the mouse corneal technique originally described by Rees and Robson (1950) in experimental tuberculosis and later applied to murine leprosy, details of the technique are given by Goulding et al (1953) and Naguib et al (1956)

The leprosy material for the present investigation was obtained from mice which, inoculated intracorneally with *Mycobacterium lepræmurium* (Douglas strain) from a rat leproma had developed generalised leprosy One mouse was killed 124 days, and the second 135 days, after inoculation, and their organs were used in preparing the suspension used in the two experiments as follows

The liver and spleen of each mouse were excised with sterile precautions and ground with a few ml of 0 05% 'Tween 80' in sterile physiological saline solution The suspension so obtained was first lightly centrifuged for 5 minutes at 500 r p m to precipitate the coarse material, and the supernatant fluid was centrifuged at 5500 r p m for 20 minutes to bring down the lepra bacilli with a very small amount of fine tissue debris This last precipitate was suspended in tween 80 saline solution and used for intracorneal inoculation

Diethyldithiolisophthalate, supplied as a transparent liquid, was used as a 50% solution in arachis oil in a dose of 5 mg per mouse every 2nd day or once a week Isoniazid was always given in a daily dose of 0 3 mg per mouse mixed with 5 g of M R C diet 41

Results

Two experiments were made on groups of 7–10 albino "C" mice In each experiment there was a control group, a group treated with isoniazid, and a group treated with the mercaptan once every 2nd day In addition to these three groups there was a group treated with isoniazid daily and the mercaptan every 2nd day in the first experiment, and in the second experiment there were two other groups one treated with the mercaptan once weekly, and the second receiving combined therapy with isoniazid daily and the mercaptan once a week The results of these experiments are shown in figs 1 and 2

In the control groups there was, soon after inoculation, an initial traumatic reaction consisting of an opaque corneal area equivalent to the site of inoculation This initial reaction faded gradually but never disappeared

The work described up to this point in the book includes Dr Wells's more important contributions to the understanding of airborne infection, and a clear account and interpretation would have been valuable Unfortunately much of the discussion is hard to follow and there are long and unnecessarily detailed descriptions of laboratory apparatus Most air bacteriologists in this country have found the slit sampler to be the most satisfactory instrument for sampling air Dr Wells apparently prefers the air centrifuge *in spite of its inferior performance with small particles*

Dr Wells then goes on to describe, in the second part of the book, his efforts to prevent airborne infections by means of "*sanitary ventilation*" *For this purpose he prefers* ultraviolet irradiation to ventilation in its generally accepted sense, and he records bacteriological and epidemiological experiments to support his claims for the efficacy of the method Some epidemiologists may not be satisfied with the statistical methods During one experiment infections occurring in an irradiated room were excluded from the results because the ultraviolet tubes had not been dusted

The chapter on dust borne infection is the best in the book Another useful feature is the comprehensive bibliography

In spite of these several criticisms, the book will be useful to the bacteriologist working on air hygiene because it provides, in one place, a record of Dr Wells's notable contributions to the subject

"STITCH-GUN" FOR SUTURING ATRIAL SEPTAL DEFECTS

OF the various closed methods of repairing atrial septal defects the most versatile is the atrial well, first described by Gross et al,[1] but placing sutures under blood by means of a needle-holder is difficult

I have devised an instrument to overcome this difficulty, it has been used in closing experimentally created atrial septal defects in animals, and suturing the margins has proved rapid and easy

The instrument consists of a head and a barrel housing a removable needle, mounted on a pistol grip (figs 1 and 2) At the pointed end of the needle is an open eye, at the other end is a thumb-plate and spring The spring prevents the needle from projecting beyond the barrel until the thumb-plate is pressed, and when the thumb-plate is released the needle automatically returns to the barrel On the pistol grip near the barrel are two spring catches to hold the thread

The suture is threaded into the grooves on the head (fig 3A), and the two long ends are secured in the spring catches The edge of the defect is palpated through the well with the left index finger, while the right hand holds the gun and places it so that the edge of the defect is in the U on the head of the gun (fig 4A) The thumb plate is then pressed and released, one end of the thread is held (fig 2), and the other *is allowed to slide through the spring catch The needle passes through the septum* at the margin of the defect, catches the thread in its eye and then pulls it back through the septal margin (figs 3B and C) With the left hand the needle is then pulled right out of the barrel, drawing with it the loose end of the thread, which now occupies the barrel (figs 4B and 3D) The fixed end of the thread is then released and the instrument removed from the heart

The stitch-gun may also be used for placing stitches elsewhere in the heart, or in other parts of the body where visibility or room to manœuvre are lacking

I should like to thank Mr A E Christmas who made the prototype for me The instrument has been made for me by Messrs Down Bros and Mayer & Phelps, 92, Borough High Street, London, S E 1

[1] Gross, R E, Watkins E, Pomeranz, A A, Goldsmith, E I *Surg Gynec Obstet* 1953 96 1

was easily expressed twelve minutes after the baby's birth but was incomplete; the patient then complained of nausea and upper abdominal pain, but her general condition was satisfactory. Some thirty minutes later there was a post-partum hæmorrhage of about 18 oz., and a succenturiate lobe was passed; the blood pressure decreased to 65/40 mm. Hg, and a dextran drip was set up, followed by blood and oxytocin in saline solution to counteract a tendency of the uterus to relax with continued slight hæmorrhage. The patient continued to deteriorate in spite of methylamphetamine hydrochloride, nikethamide, and continuous oxygen, and died three hours after delivery. The total estimated blood loss was 50 oz., and the blood did not clot.

Necropsy Findings.—Subarachnoid hæmorrhage, hepatic subcapsular hæmorrhage, pulmonary bronchial and alveolar hæmorrhages. The lungs showed numerous small infarcts with areas of collapse and emphysema. There was general congestion, with many pigment-laden phagocytes, but no evidence of fibrin emboli. Pancreas, kidneys, and adrenal glands were normal. An especially interesting feature was the failure of the blood to coagulate either before or after death; the fibrinogen content of the plasma taken before death was less than 100 mg. per 100 ml.

Case 2.—Gravida 2, aged 26, admitted as an emergency at 10 A.M. on July 9, 1955, with abdominal pain at the 35th week of gestation. The history was of swelling of the ankles and headache with the sudden onset of pain in the lower abdomen nine hours before admission. Her general condition was good, blood pressure 120/70 mm. Hg, pulse-rate 120; the uterus was larger than the dates suggested and was tense and tender; the fœtal heart was not heard. There was no vaginal bleeding; slight ankle œdema and heavy albuminuria were present. Blood taken for cross-matching did not clot; bleeding-time $3^{1}/_{2}$ minutes. At 8.30 P.M. no plasma fibrinogen could be found; labour was induced at this time, and a stillborn child was delivered at 3.20 A.M. next morning. The placenta was retained in spite of the administration of intravenous ergometrine, and a steady trickle of blood continued; the patient's general condition, which had begun to deteriorate even before delivery, now became serious in spite of the intravenous administration of 'Dextraven' and blood; by 5 A.M. improvement had taken place, and fibrinogen 0.75 g. was given intravenously, followed by manual removal of the placenta. About $1^{1}/_{2}$ pints of clot came away with the placenta, but bleeding continued, and the uterus was packed. Fibrinogen 0.75 g. was also given with the sixth pint of blood, and the patient began to improve slowly and had no further loss. Albuminuria was present in the puerperium, but there was no oliguria, and the fibrinogen level on the tenth day was 250 mg. per 100 ml. (i.e., normal). Bruising at the site of the intramuscular injections was observed up to the fourth day of the puerperium but not afterwards.

Case 3.—Gravida 3, aged 26, 36 weeks pregnant, admitted as an emergency on July 16, 1955. She had had slight backache on the previous night, since when she had felt no fœtal movements; at 9 A.M. before admission the backache recurred, followed by severe abdominal pain and vaginal bleeding. She was admitted at 4.30 P.M. with blood-pressure 130/80 mm. Hg, pulse-rate 92, typical signs of accidental hæmorrhage, fœtal heart sounds absent, and heavy albuminuria.

5.15 P.M.—Blood taken for cross-matching did not clot. No plasma fibrinogen was present.

7.5 P.M.—Artificial rupture of membranes.

9.4 P.M.—Fibrinogen 0.3 g. was given intravenously.

9.6 P.M.—Plasma fibrinogen 100 mg. per 100 ml. The blood clotted after ten minutes, but this was soft and began to disintegrate slowly though not completely.

10.7 P.M.—Plasma fibrinogen 80 mg. per 100 ml. Clot after ten minutes but soft, non-retractile, and partly redissolved.

11.15 P.M.—Plasma fibrinogen 46 mg. per 100 ml.; soft gelatinous clot, which completely dissolved in thirty minutes.

July 17, 12.15 A.M.—Oxytocin drip set up; contractions started within fifteen minutes.

2.5 A.M.—Precipitate delivery of stillborn infant; intravenous ergometrine given, and placenta expelled with about 2 pints of watery blood and 1 pint of clot. At the time of delivery fibrinogen 0.45 g. was given into the blood drip. The patient's condition remained good, without any post-partum hæmorrhage. The placenta showed a crater covering half the surface with adherent dark red clot.

Two days after delivery the plasma fibrinogen was 250 mg. per 100 ml. (normal), and Hb 50%; there was heavy albuminuria but no oliguria. By the fifth postpartum day there was only a trace of albuminuria, and Hb was 63% as a result of transfusion and intravenous iron. The patient was discharged later in good condition.

So far as possible the whole of the blood evacuated from the uterus at the delivery of the placenta was collected for estimation of its fibrin content; the extraordinarily large amount of 63 g. was found, which is very much greater than that normally present in the circulating blood at any time.

Pathology

The plasma fibrinogen levels were estimated by the micro-Kjeldahl method (King's modification). The amount of fibrin in the clot from the uterus in case 3 was estimated as follows:

The clot was washed with water, expressed, and dried as far as possible, and weighed. An aliquot portion was digested with 30% NaOH, and the protein was estimated by the biuret method; the result was expressed as grammes of fibrinogen.

The estimate is probably high but not more than +15%. The normal value for fibrinogen in the pregnant female is about 300 mg. per 100 ml. The blood volume of a healthy woman by the congo-red method is 70–100 ml. per kg. of body-weight, and a little higher in pregnancy. If the patient's blood volume was 6 litres, this amount would be equivalent to 18 g. of fibrinogen.

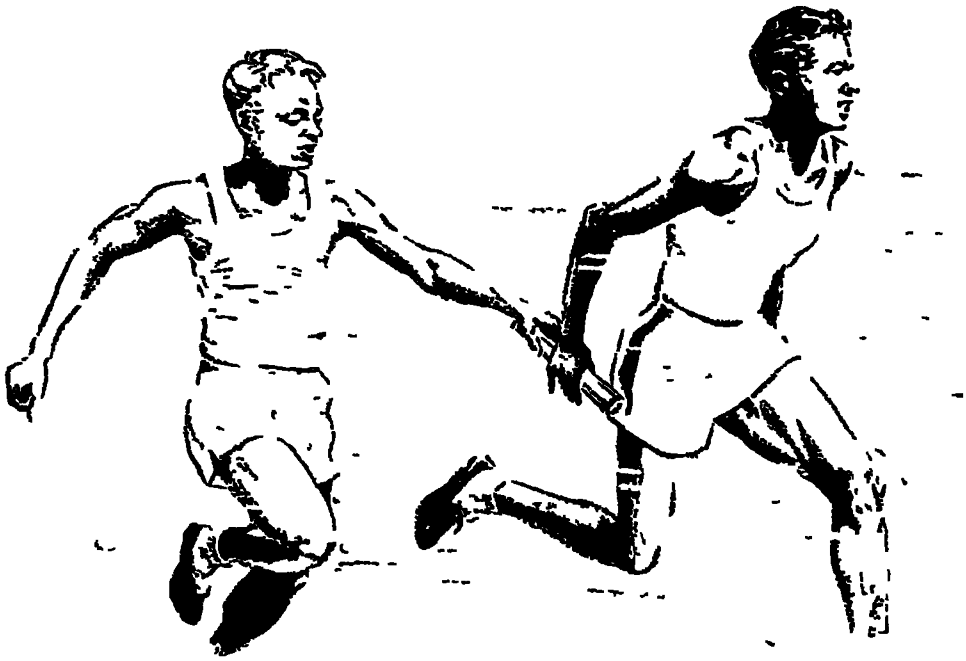
All fibrinogen is made in the liver (Tarver and Reinhardt 1947), and it is likely that there is a rapid turnover of the blood-proteins. Experiments on rabbits show that, when the fibrinogen is reduced as much as 90%, regeneration takes place in five or six hours (Drury and McMaster 1929). Greenberg (1951) estimates that there is a complete turnover of the blood-protein in from four to ten days. In case 3 about twenty-four hours elapsed between the original hæmorrhage and delivery, and at a rough estimate the patient may have replaced her fibrinogen at the rate of 1.5 g. an hour. If the mechanism for the production of fibrinogen was unimpaired, this would allow for the formation of an additional 36 g. of fibrinogen. With the 18 g. originally present this totals 54 g., which might have been serially deposited in the uterine clot. Our estimate from the clot was 63 g.

Discussion

These three cases present interesting contrasts and raise theoretical and practical problems. Cases 2 and 3 had partially concealed accidental hæmorrhage, which Schneider (1951) has shown to lead to the release of thromboplastin, causing the conversion of fibrinogen to fibrin. Case 1 had a retained succenturiate lobe and a postpartum hæmorrhage; she was toxæmic and pyrexial before delivery. We are therefore uncertain whether the cause was failure of fibrinogen formation owing to toxæmic or infective liver damage or to the liberation of thromboplastin from the uterus.

A second problem is the fate of the precipitated fibrin; Schneider (1951) suggests that it is deposited within the arterioles, especially of the lungs. Histological examination of the lungs in case 1 failed to show these "fibrin emboli," though the numerous small infarcts discovered might be connected with such a phenomenon. The amount of fibrin in the intra-uterine clot in case 3 suggests that, in some cases at least, the fibrin is deposited in the uterus more or less completely.

A third problem of great practical importance is the speed and duration of the defibrinogenation process; this is linked with the question of the best method of replacing fibrinogen. In case 2 it was argued that, since defibrinogenation continued at least until delivery of the



Smooth take over

Bidormal provides the ideal answer to the management of insomnia It's two-phase action ensures steady sedation throughout the night

As the effect of the short-acting barbiturate pentobarbitone, contained in the outer shell of Bidormal, begins to fade, the action of the butobarbitone, contained in the inner core, takes over smoothly ensuring calm uninterrupted sleep for approximately eight hours

TABLE I—AGE-DISTRIBUTION OF CORONARY HEART DISEASE IN 1000 NECROPSIES

Age (yr.)	No.	Coronary heart disease
<50	200	23 (11.5%)
50–59	297	66 (22.2%)
60 or more	503	155 (30.8%)

characteristic pain of cardiac ischæmia (Evans 1948) could usually be distinguished from the chest pain found in chronic pulmonary disease. The latter, though sometimes related to dyspnœa on exertion, was usually sharp and knife-like and of more variable onset, distribution, and duration in the same patient than the pain of cardiac origin.

Cardiac hypertrophy may be a feature of coronary heart disease (Boas 1951, Master 1954, Yater et al. 1948); in at least 37 of the 1000 necropsies the heart weighed more than 380 g. (range 380–880 g., mean 460 g.), but the kidney structure showed no evidence of hypertension, and no cause could be found other than coronary heart-disease. The increase in weight was largely due to left ventricular hypertrophy. By contrast, cardiac hypertrophy developing in pulmonary heart disease in the absence of coronary disease is mainly right ventricular in origin. Otherwise unexplained left ventricular enlargement in association with pulmonary disease, we think, is usually evidence of coronary heart-disease.

Study of the 134 cases which came to necropsy confirmed the diagnostic importance of the accepted criteria and of the lesser electrocardiographic signs described by Evans and McRae (1952) in the presence of massive fibrosis of pneumoconiosis, even in the absence of cardiac pain. ST–T changes with left ventricular preponderance in the presence of massive pulmonary fibrosis were found to be reliable evidence of coronary heart disease where other causes of left ventricular preponderance could be excluded.

TABLE II—AGE DISTRIBUTION OF CORONARY HEART DISEASE IN 134 CASES OF PNEUMOCONIOSIS STUDIED CLINICALLY AND AT NECROPSY

Age (yr.)	No.	Coronary heart disease
<55	54	11 (20.4%)
55–64	54	20 (37.0%)
65 or more	26	13 (50.0%)

These preliminary studies suggested a high prevalence of coronary heart disease in coalminers who came to necropsy. We recognised, however, that only limited conclusions should be drawn from such necropsy material (Mainland 1953) because no allowance could be made for the effects of differential mortality-rates and of case selection. The main study was therefore designed to find out if the observed 22–37% prevalence of coronary heart disease was typical of all miners and ex-miners in the older age group living in the area.

Prevalence in a Representative Sample of the Community

Method

55 names were selected at random from the Hollerith cards relating to the population of 1160 miners and ex-miners who were aged 55–64 on Jan. 1, 1954, and were living in the Rhondda Fach valley at the time of a private census conducted the previous summer (Cochrane 1954).

The men were visited in their homes and invited to attend as outpatients for an investigation of breathlessness. Transport was provided and loss of earnings made good. 4 men were seen on three afternoons in each week and subjected to clinical and electrocardiographic examination and assessment of respiratory function. A history of smoking habits was also taken. The method and findings of the physiological assessment are presented in detail elsewhere (Cotes et al. 1956).

Standard limb leads, unipolar limb leads, and chest leads V_1, V_4, and V_6 of the electrocardiogram were obtained at rest during quiet respiration and during full inspiration and expiration. The ballistocardiogram was recorded with a critically damped table having a flat frequency response curve and fitted with a mechanical oscillator to provide a dynamic calibration (Timbrell 1956). The standard electrocardiographic leads were recorded simultaneously.

Criteria for Diagnosis of Coronary Heart-disease

The criteria used for the diagnosis of coronary heart disease were those recognised in normal clinical practice but expanded and modified in the light of the preliminary studies described above.

A history of cardiac infarction and the diagnosis of it in retrospect were both accepted as evidence of coronary heart disease. It was recognised, in view of the high proportion of silent cases found in the preliminary study, that attacks of coronary occlusion might be atypical or silent in patients with pneumoconiosis (as in others) and would only be revealed by electrocardiography.

Left ventricular enlargement detected radiographically, in the absence of any other cause for its presence, was regarded as supporting evidence of coronary heart disease, particularly in the presence of pulmonary disease.

Electrocardiography

The electrocardiogram will show evidence of the effect of coronary insufficiency on the myocardium. The coronary insufficiency may be transient or prolonged, and the damage to the myocardium minimal or great, diffuse or localised. Changes indicating infarction of the heart are accepted as evidence of coronary heart disease. Signs of chronic or protracted ischæmia, with or without cardiac pain, may be present, in which part or whole of the insufficiency is due to coronary artery disease although there may be other disease—e.g., pulmonary disease—present at the same time. The presence of aortic-valve disease must also be detected and assessed.

Certain changes in the electrocardiogram are readily acceptable as evidence of this myocardial change resulting from ischæmia if other causes are excluded. These changes are often superimposed on an electrocardiogram showing left axis deviation, and this is important when pulmonary disease is also present.

The ST segment may be depressed in one or two standard leads and in one or more chest leads. There may be preterminal negativity of the T wave. These changes are seldom absent over some part of the left heart in coronary heart disease, and the peculiar shape of the tracing must be regarded as more important than the absolute degree of the depression of the ST segment (Holzmann 1952).

The presence of deep notching by a Q wave in lead I is abnormal. This does not apply to lead III, but the criteria for abnormality of the QIII or QSIII deflections, and their frequent association with coronary-artery disease, have been described (Ungerleider and Gubner 1947). The effect on lead III of deep held inspiration may also be of diagnostic value (Evans 1951); persistence of the Q wave for 0.04 sec. or more is considered abnormal.

Depression of a portion of the ST segment to form a trough, claw, or wing deformity, with low or blunted T waves in leads over the left ventricle, has been described in early myocardial injury associated with cardiac pain (Evans and McRae 1952). The significance of these signs in the diagnosis of coronary heart disease was confirmed in the preliminary study. These and other changes in the ST–T segments of the electrocardiogram are, however, tion of the Masters of the Supreme Court, and it would be a simple matter for the Master who examines the pleadings to order the reference of disputed medical matters to an independent expert The only real advantage of the informal pre-trial conference as used in the United States is its conscious search for the basis of a settlement out of court Even where settlement is impossible, the use of independent reports would help to remove at least the medical issues from the area of dispute Where the medical issues cannot be resolved before trial, an independent witness will be above any suspicion of partiality (suspicion of partiality by expert witnesses is probably not so great in this country as seems to be the case in New York, but it exists to some extent) But it is unavoidable in such cases that the expert should be called to give oral evidence and be liable to cross-examination, and that, in its turn, must give counsel the right to call other medical evidence That course may not be welcomed by those who feel that there is something discreditable about a clash of expert opinion in open court But English judges and lawyers are not likely to concede (any more than their colleagues in New York have done) that only one expert should be heard

There remains the question whether the British taxpayer would or should pay the bill for such a system of expert testimony The New York scheme was financed in its early stages by a grant of $20,000 each from the Alfred P Sloan Foundation and the Ford Motor Company Fund, but the cost is now borne by public funds If a similar arrangement was introduced here, it would hardly be feasible to limit it geographically, as has been done in America And the cost of a scheme applying to the whole country could probably be met only by the Exchequer The New York report suggests, however, that the cost of the project there was more than offset by savings in other ways The British reader may wish that the report had analysed this aspect more fully, but it does at least seem probable that a comparable plan in this country would be by no means as costly as it seems at first sight

Recurrent Dislocation of the Shoulder

Is recurrent dislocation of the shoulder largely preventable? It is surprising that we do not yet know the answer One school of thought holds that after reduction complete immobilisation with the forearm across the chest for 3-4 weeks is essential if recurrence is to be avoided, only thus, they say, will the torn structures in front of the shoulder-joint heal adequately The other school maintains that this immobilisation is an unnecessary imposition on the patient and that early movements are harmless In their view, recurrence or otherwise depends on the damage done by the original injury, if there is an avulsed glenoid labrum or a depressed fracture of the humeral head the patient is bound for later trouble, and immobilisation will not heal the one or restore the other to normal contours Neither side really knows, and one of them must be wrong it should not be hard to decide which Figures derived from series of patients treated at the time of original injury by one or other method are of very little value on this point the high proportion previously treated by early mobilisation is suggestive, but not significant unless we also know what proportion of *all* primary dislocations are treated by each method in that surgeon's particular "catchment area" In spite of the influential teaching of WATSON-JONES and others, it is probably true to say that most primary dislocations in this country still have less than one week's immobilisation and that often very incomplete McLAUGHLIN and CAVALLERO [1] recorded a high recurrence rate after early movement, but they included no adequate control group in which the joint was rigidly immobilised A definite answer would be given by a follow up study of a few hundred cases treated by each method Dislocation of the shoulder is common, recurrence when it comes, usually strikes within a year, and it is not so rare that a great many patients would have to be followed before getting at least a helpful indication

The primary treatment is, of course, not the only factor determining recurrence Age does not seem to be of much importance, and there is now less support for BANKART's view that the *mechanism of the original dislocation* in patients who have recurrences is always a fall backwards on to the shoulder or elbow so that the humeral head is driven directly forward Many workers, such as ADAMS [2] and DU TOIT and ROUX,[3] have reviewed this question and all the evidence indicates that there is no essential difference in the liability to recurrence, however the original dislocation was produced But there may well be anatomical abnormalities that predispose to recurrent dislocation, particularly variations in the attachment of the glenoid labrum and the size of the glenoid cavity, and it is significant that in GALLIE's series [4] of 200 cases there were three pairs of brothers and two pairs of twins Furthermore the condition is quite often bilateral, and this, for different reasons, is particularly so in epileptics There will always be some recurrent dislocations of the shoulder which start insidiously, or with trivial strains producing momentary subluxations, and then, with repetition, eventually progress to true recurrent dislocation

In the established case all the basic pathological changes have been known, though not always appreciated, since the 19th century, later workers have varied only in their opinion of the frequency and importance of the lesions from an ætiological standpoint There seems no doubt whatever that in most patients the vital factor is inadequate support for the humeral head at the anterior glenoid margin, whether due to *avulsion of the glenoid labrum* (BANKART's lesion), stripping of the capsule itself from the neck of the scapula, or even a stretched and lax capsule. BANKART's lesion is certainly not always present, in modern series its incidence varied from 65% to 100%, and it is interesting to note that in a recent review by DICKSON and DEVAS [5] of patients operated on by BANKART himself, or strictly according to his technique, only 32 of the 50 cases available for follow up had been found at operation to have the classical lesion With any lesion of this type there may be secondary atrophy and rounding off of the bony glenoid margin The second important site of abnormality is the posterolateral part of the humeral head, where a defect may be found which is apparently due

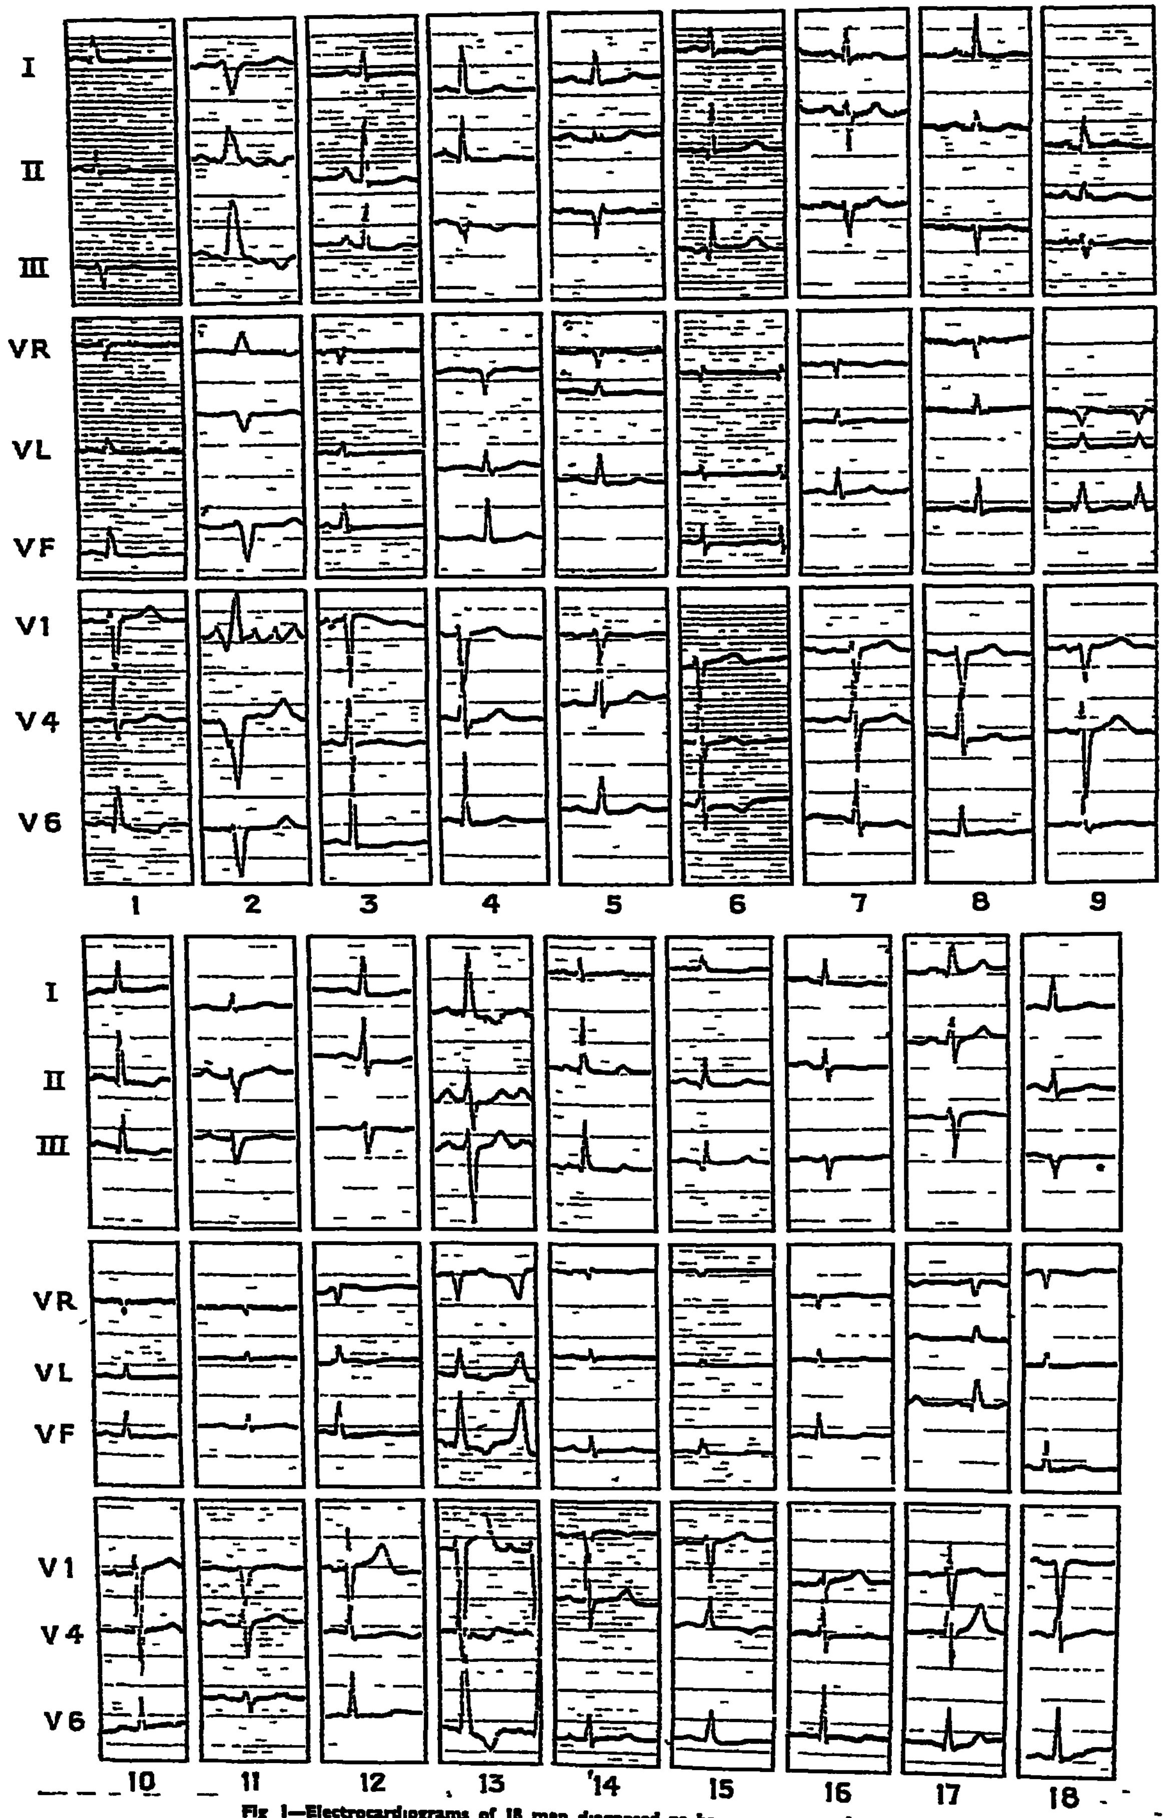

Fig 1—Electrocardiograms of 18 men diagnosed as having coronary heart disease

The ackee was studied again by HASSALL and REYLE,[8] and they isolated from extracts of its seeds two new polypeptides, hypoglycin A and B, which could produce fatal hypoglycæmia in laboratory animals This discovery not only was of importance to the possible rôle of the ackee in vomiting sickness, but suggested a new search for other plants of equal pharmacological interest ASPREY and THORNTON [9] made a valuable survey of medicinal plants of Jamaica, and their lists made it possible for the first time to identify accurately the scores of different local plants used regularly in bush teas by the Jamaican peasants HUGH-JONES [10] clinically tested the efficacy of some of these bush teas that were claimed to cure diabetes, but none was found to have a direct hypoglycæmic action like the extract of ackee seeds This ackee extract was not tested in man, partly because adequate quantities were not then available for clinical trial, but particularly because further animal work was judged to be necessary before the extract could be said to be safe for use in man The study of these hypoglycins may be as important to the fuller understanding of carbohydrate metabolism and diabetes mellitus as the investigation of the hypoglycæmic action of certain sulphonamides by JANBON and his associates,[11] to which we referred in a recent leading article [12]

Meanwhile the exact cause of vomiting sickness is still a mystery The circumstantial evidence against the ackee is high But ackees are a nutritious, cheap, and attractive food eaten with impunity by tens of thousands Rather than vainly attempt to ban the ackee, we must determine under what conditions hypoglycins appear in the arillus, whether preliminary starvation is necessary for the development of toxic hypoglycæmia, and whether other Jamaican plants ever contain these dangerous, but fascinating, substances

Annotations

WOUNDS WITHOUT DRESSINGS

WHILE the major risks of surgery have steadily diminished over the past fifty years, many of its minor inconveniences have remained as irksome to the patient as ever Surgeons who have been subjected to surgery themselves must have been struck by the many trivial but painful procedures that follow the main performance in the operating-theatre Unlamented the bedpan is on its way out, and early ambulation seems to be on its way in Palumbo et al [1] have lately questioned once more the need for another uncomfortable feature of the postoperative routine—namely, the dressing of wounds

Earlier supporters of the "no dressing" school were Berkeley and Bonney [2] and several workers in America [3 4], but many surgeons remained unconvinced Palumbo et al have now treated 222 clean surgical wounds, in half of which the dressings were left in place for several days while in the other half they were removed after 6–24 hours The wounds included a wide variety of thoracotomy, laparotomy, and hernia incisions, and the investigators believe that complications were slightly less common in the group exposed to the air from the first day

It is perhaps a testimony to the profession's frequently unquestioning conservatism that there will be few to whom this will come as a surprise We have all learnt that cleanly incised wounds are sealed off by fibrin within a few hours of surgical closure, and that granulation tissue bridges the gap with astounding rapidity We have come to appreciate in the exposure treatment of burns that coolness, dryness, and light are bacteriostatic agents not to be despised, even in an era of antibiotics We know, or should at least suspect, that most wound infections are due not to stray staphylococci but to inadequate hæmostasis Thus, persistence with the ritual of prolonged wound dressing may spring more from deference to tradition than from scientific reasoning

Palumbo and his collaborators feel that "in these days of shortages in trained professional personnel, increasing living and hospital costs and need for economies it is necessary to develop and place in operation any method that will be beneficial to the patient, to the hospital, and to the trained personnel " Obviously much nursing time and effort can be saved More important, however, the patient can be spared changes of dressing—an unpleasant business even in the gentlest hands In the past such minor ordeals may have seemed trivial compared with the paralysing struggle under the anæsthetic mask or the nauseating discomfort of the immediate postoperative period Today, when even major operations leave but few unpleasant memories, they linger on in the mind—especially in the minds of children

The no-dressing method does, however, raise at least one problem which is mentioned and dismissed by Palumbo "There was no apparent opposition by the patients, relatives or visitors to seeing the incisions without dressings In fact, most patients were eager to watch their wounds during the healing process" This may be more true in America, where the layman is encouraged to take a much more active interest in his body's welfare than in this country

The method also invites comparison with the plastic 'Nobecutane,' an acrylic resin which, when dissolved in a mixture of acetic esters,[5] can be sprayed on wounds and forms over them a strong, thin, elastic, and transparent covering It can stay on until stitches are removed, and, being freely permeable to air and water (though not to bacteria), shares with the no-dressing technique the merit of allowing frequent inspection, a daily bath before the removal of stitches, and greater freedom for the patient to move about Over the no-dressing technique nobecutane has the advantage of making even an initial gauze and wool dressing unnecessary, of actually helping to hold the skin edges together, and (most important) of being applicable to a wide variety of outpatient and casualty procedures Rob and Eastcott,[6] who have used it to their satisfaction, do, however, mention some minor disadvantages The material is inflammable in the liquid form (though not after it has dried on the skin), the removal of stitches may be slightly painful because their ends catch on the plastic, its application is somewhat uncomfortable on an unanæsthetised raw surface, and, owing to the vasodilator properties of the solvent, it causes considerable oozing of blood As for this last disadvantage, Ellerker [7] feels that, though the accurate hæmostasis and skin apposition necessary to overcome it may be time consuming to the surgeon it is time well spent in the patient's interest probability, is in agreement with the observations that the ballistic impulse may be reduced below normal in coronary-artery disease (cf Scarborough et al 1952) The abnormalities in the form of the tracings were similar to those reported by these workers

Smoking Habits

No significant relationship was obtained between the consumption of tobacco and coronary heart-disease when the consumption was expressed as the present intake or the average intake over life However, 7 of the 10 men who volunteered an intake or more than 25 g of tobacco daily for any period had coronary heart-disease

Discussion

Coronary heart-disease was diagnosed in 38% of the men in a sample drawn at random from the population of miners and ex-miners, aged 55–64, living in the community Half these men were known cases or presented with positive clinical findings, the other half had no symptoms attributable to coronary heart-disease, and this was only detected after a special search for its presence The total prevalence and the proportion of silent cases are similar to those found in the preliminary clinical and pathological investigation A higher prevalence might perhaps have been expected among these cases than in the random sample (cf Kilpatrick et al 1954, Mainland 1953) because coronary heart disease was a contributory cause of death in some instances

The sample of the population studied, and the men with and without coronary heart-disease, were typical of the whole as regards the prevalence of pneumoconiosis and chronic bronchitis, for which other estimates were available (Cotes et al 1956) Those with coronary disease had worked underground and at the coal-face for periods similar to those of the remaining men, and we found no evidence that the sample was in any way unrepresentative

The 38% prevalence of coronary heart disease might be compared with the 38% prevalence of all types of heart disease found in a group of men, aged 55–64, undergoing annual medical examinations in a United States industrial concern (Franco 1952) Not all of these men had coronary heart disease, however, and the method of selection in Franco's series may have increased the proportion of early cardiac cases while excluding those with much disability Gover (1948) obtained a 21% prevalence of clinical heart-disease in white men, aged 55–64, who formed part of the families of, or were, applicants for loans under a U.S farm rehabilitation programme All types of heart disease were included, but electrocardiograms were not recorded, and the number of men with a positive medical history is likely to have been underestimated Data comparable with our own on the total prevalence of coronary heart disease in a living population are not yet, but should soon become, available from studies in progress both in this country and in the U S—e g, Boas and Epstein (1954), Dawber et al (1951), Fales (1951), and Hilleboe et al (1954) Our findings on the relationships between coronary heart-disease and blood-pressure, body-weight, and consumption of tobacco are in agreement with the findings of other investigators—e g, Doll and Hill (1954), Hammond and Horn (1954), Keys (1954), and Parkinson and Bedford (1928)

The standardised mortality-rates in 1950 of deaths due to coronary heart disease in men aged 20–64 (Registrar General 1954) for coal hewers and getters (social class III) and other mine workers in coal (social class IV) were respectively 90 and 78, or 107 and 84 if deaths classified under myocardial degeneration are included These data suggest an average prevalence of coronary heart-disease among coal-workers In the absence of other figures for comparison the apparently high prevalence found in the present investigation is not necessarily remarkable, in view of the proportion of silent cases and the known high prevalence of coronary atheroma at this age A relatively low prevalence of disabling myocardial ischæmia might be anticipated in this population if the relationship between coronary heart-disease and physical activity which is found among workers in the Post Office and in London Transport (Morris et al. 1953) is also applicable in heavy industry Heavy work may, however, be in a class by itself in this respect (Rentoul 1951) In fact, at least 7 of the present 47 men had been in bed at some time through myocardial ischæmia, giving a 15% prevalence of active or latent coronary-artery disease sufficient to cause absence from work This figure may be compared with a 7% prevalence found in medical practitioners in the same age group (Morris et al 1952) This apparent difference is unrelated to pneumoconiosis or to "bronchitis" It is unlikely to be due to differences in smoking habits because miners are likely to consume relatively little tobacco This expectation has been confirmed in other studies in the Rhondda Fach (Higgins 1956)

The difference we have found could be explained on a survival basis if, as has been suggested—e g, Stocks (1954)—manual workers have a lower case fatality rate from cardiac infarction than those in other occupations, in these circumstances, even with the same attack-rate, a higher prevalence of coronary heart disease might be expected

Conclusions

A detailed clinical and physiological study was made of a sample drawn at random from a complete population of coal-workers aged 55–64

The 8% lapse rate for men living in the area at the time of survey was no higher than that for the preceding X-ray survey of the same population

The 38% prevalence of coronary heart-disease in this population of elderly coalminers and ex-miners is higher than that previously reported, and underlines the need for further investigations of this type

Summary

The prevalence of coronary heart disease was investigated in 47 of 55 men selected at random from a whole community of coalminers and ex-miners aged 55–64 Ballistocardiography was also done

38% of the men were found to have coronary heart-disease as defined, half of these (19%) had symptoms and the remainder (19%) were silent cases 15% of the men had at some time been in bed through myocardial ischæmia

The mean systolic and diastolic blood-pressures for the men with coronary disease (165 8/89 4 mm Hg) were higher ($P<0$ 05) than those for the remaining men in the sample (139 5/80 7 mm Hg)

The mean body-weights for the two groups were 156 9 lb and 133 8 lb respectively. The variation in body-weight was significantly greater in the men with coronary disease ($P<0$ 02), hence the significance of the higher average is uncertain, though it appears to reach the 5% level

We wish to thank Dr William Evans for his advice and criticisms, Dr Richard Doll for help in formulating the smoking questions, Dr W R L James for collaboration in the preliminary investigation, Dr J N Morris for reading the manuscript, our colleagues at the Pneumoconiosis Research Unit, especially Dr J C Gilson, director, Mr P D Oldham Dr T G Morris, and Mr R G Carpenter, for coöperation in the various stages of the survey, Mrs G M Budd and Mr G Jonathan for home visiting, and to Mrs J Newman and Mr A J Merrick for technical assistance

operation in any individual depends mainly on his general condition and the type of arterial lesion , and the lesion is best analysed by arteriography, which has now become essential before any major surgical step is contemplated

PNEUMOCONIOSIS

IN a new Medical Research Council report[1] Dr J C Gilson and Dr P Hugh-Jones, of the council's Pneumoconiosis Research Unit in South Wales, describe the investigation they began in 1949 into the variations in lung function during particular stages of coalworkers' pneumoconiosis They are especially concerned with the cause of the disproportionate breathlessness associated with the condition, and the relation between the severity of the breathlessness and the *appearances of the chest* radiograph As we noted in a recent leading article,[2] Browne and his colleagues have lately cast doubt on the value of radiography in the assessment of pneumoconiosis , and these findings suggest that the existing compensation machinery for miners' pneumoconiosis should be reconsidered

From a review of work done in various countries Gilson and Hugh-Jones show that although much has been learned about lung-function tests neither the cause of the breathlessness nor the relation of its severity to the radiographic appearances has been properly established The report is concerned with the effects of prolonged inhalation of coal dust alone, which can cause a disabling form of pneumoconiosis different from silicosis The disease consists of two distinct pathological processes which may be distinguished radiographically "simple pneumoconiosis" due to the retention of coal dust, and progressing only if dust exposure continues , and "complicated pneumoconiosis" characterised by a superimposed infection with progressive massive fibrosis and advancing independently of any further dust exposure

Gilson and Hugh Jones studied 40 normal non-miners and 118 miners between the ages of 23 and 60 All the miners had had at least ten years at the coal face , and they were grouped into four different radiological stages of coalworkers' pneumoconiosis There was also a control group of normal working miners All the subjects were divided into age classes so that the effects of age and X-ray category could be separated The experiment was designed to determine the nature of the disturbance of lung function in pneumoconiosis, and to decide which combination of tests provided the best measure of disability The tests used were chosen for simplicity repeatability, discrimination (between normal and diseased states), and validity and they included besides clinical and electrocardiographic examinations, standard exercise ventilation and blood oxygen saturation, the total lung capacity *and its subdivisions diaphragm* movement, maximum voluntary ventilation, and intrapulmonary gas mixing and transpulmonary gas transfer by a new technique of recording the uptake of helium and carbon monoxide simultaneously

The exercise test was standardised for differences in weight, and age was taken into account , the exercise ventilation, taken as a percentage of the maximum voluntary ventilation (the "dyspnœic index") was the best index of breathlessness and compared well with independent clinical assessment The results show *that* breathlessness on exertion in coalworkers' pneumoconiosis is mainly caused by a reduction in the ventilatory capacity of the lungs The increasing air requirement associated with exercise accounts for only a small proportion of exertional dyspnœa it is the lung reserve which becomes severely limited with *increasing radiological abnormality* Gilson and Hugh Jones conclude that "in coalworkers' pneumoconiosis the excessive feeling of breathlessness on exertion results primarily from a diminution of the maximum ventilatory capacity of the lungs, and only to a relatively small extent from increase in the ventilation required for exercise"

But, especially in advanced disease, there is some increase in air requirement evidence of right heart strain shows that the pulmonary circulation is disturbed and, combined with ventilatory inequality between different parts of the lungs, as shown by helium mixing tests this suggests that the gas transfer deficit responsible for the increased ventilation is the result of changes in ventilation perfusion ratios The inequality of ventilation in the lungs increases with the degree of pneumoconiosis, the presence of massive shadows does not further increase the inequality until the latest stage of complicated pneumoconiosis, when it becomes much worse—although even then not *as severe as in advanced non industrial* emphysema A moderate degree of undersaturation of the blood with oxygen may often be found in complicated pneumoconiosis, but it is rarely severe , it is related to the inequality of ventilation, and in the latest stage to failure of the circulation also, with disturbed ventilation perfusion ratios Men in this stage have considerable functional emphysema, as measured objectively by a combination of several tests Those with simple pneumoconiosis have more evidence of emphysema than miners without the disease, but this functional change is severe only in the complicated form

As for the relation between the radiographic appearances *and breathlessness, in simple pneumoconiosis* it is age rather than the extent of the disease which is important in predicting the degree of disability In general, there is some breathlessness in simple pneumoconiosis, but this form of the disease causes only slightly more breathlessness than that which develops in *normal men* as they grow older In complicated pneumoconiosis on the other hand, breathlessness is nearly always severe, it increases with radiological abnormality , and it is augmented by increasing age

Gilson and Hugh Jones discuss the importance of the prevention of disability by periodic medical examination of miners In this respect *it is significant that* simple pneumoconiosis progresses only whilst exposure to dust continues, the extent *of* the disease being determined by the total dose of dust , and massive fibrosis arises only in the presence of considerable simple pneumoconiosis and then progresses in the absence of further dust inhalation Therefore, if dust suppression is adequate, and simple pneumoconiosis does not progress too far, little disability is caused , hence the necessity for periodic examination and removal *from* exposure to dust of those men who show signs of the disease

The report contains detailed accounts of the physio*logical function tests, together* with theoretical treatments of gas distribution and exchange in simple models and examinations of the basis of the methods used There is also a discussion of open and closed spirometry *tech*niques, and much else that is primarily of interest to the physiologist A factor analysis of the *results* shows to what extent supposedly different tests of lung function overlap The results of the various tests are finally represented most ingeniously on a three dimensional model so that partial correlations between tests may be readily seen, and those tests which measure practically the same thing are easily picked out On the usefulness *of tests, Gilson and Hugh Jones* declare "If an effort is made to find a combination of tests with minimum overlap, each one does not necessarily measure disability, since they may not be limiting factors It would appear that the best *combination* is likely to be some measure of maximum ventilatory capacity, possibly associated with tests to determine factors such as air flow resistance and lung viscance which limit the function together with a test of both non absorbed and absorbed gas uptake"

They are *to be* congratulated on the valuable contribution they have made *to the study of pneumoconiosis*

Anterior oblique radiographs of the chest, repeated to show callus-formation, may reveal the fracture (Richardson 1936, Cramer 1943, Swineford and McKinnon 1945, Bodenheimer 1948, Douthwaite 1949, Mitchell 1951)

Case 15 fractured a rib when she turned in a chair and coughed simultaneously This association of asymmetrical posture with coughing was noticed by Seilin (1917), whose patient sustained a right sided rib fracture when she coughed with her right arm outstretched to close a window Atkinson (1898) reported a cough fracture in a patient who was hanging a heavy overcoat on a hook when an attack of coughing occurred

Case 16 is unusual in that there were bilateral multiple symmetrical fractures (the right ribs were fractured 3 weeks after the left) and in neither instance did the fractures follow a bout of coughing Mitchell (1951) declared that pain often came on gradually and many of his patients were surprised to learn that they had broken a rib

Site of Fracture

In the cases reported by Oechsli (1936) the fractures occurred "on a line extending from a point 4 cms from the costo chondral articulation of the 4th rib, obliquely caudally and laterally to the 9th rib in the mid-axillary line" This is the site of interdigitation of the external oblique and serratus anterior muscles Oechsli's series included no fracture below the 9th rib, and none of the patients were pregnant Richardson (1936) noted that the majority of fractures were at approximately the junction of the anterior and middle third of the rib

In the 4 cases in late pregnancy reported by Paulley et al (1949) the fractures involved the 9th–11th ribs and continued in a caudal direction the line described by Oechsli (1936)

In the 16 cases of stress fracture reported in pregnancy, the 6th–11th ribs have been involved, in 13 cases the fracture was on the left side, in 1 case on the right side (see accompanying table) and in 2 cases bilateral, in 2 cases the side is not recorded

Mechanism of Fracture

The earlier workers (Tunis 1890, Seilin 1917) suggested that the muscular pull of the diaphragm accounted for stress fractures of ribs This is clearly not so, since the fracture line lies well above its costal slips of origin

The line along which stress fractures occur corresponds to the interdigitation of the external oblique muscle inferiorly (ribs 6–12) and of the serratus anterior (ribs 1–8) and the costal slips of latissimus dorsi (ribs 9–12) superiorly Quiet expiration is normally passive, but in forced expiration additional expulsive effort is provided by the muscles of the abdominal wall and by the latissimus dorsi muscle, which contract suddenly and energetically.

In late pregnancy the costal margin is everted, owing to the enlarged uterus, and evidence that the lower ribs are then normally under stress is provided by the frequency of pain and tenderness of the interchondral joints between the 8th and 10th costal cartilages during the last 4 weeks of pregnancy An additional shearing stress brought about by the upward pull of the latissimus dorsi and serratus anterior (especially if the arm is abducted) and the downward and medial pull of the external oblique, on a rib already under strain, could provide conditions for stress fracture

Summary

13 reported cases of stress fractures of ribs in pregnancy are reviewed and 3 further cases are described Of these 3, 1 was unusual in that coughing was not responsible for the fracture

When a patient in late pregnancy suddenly has pleural pain, possibly initiated by coughing, with tenderness over the lower ribs, stress fracture should be considered and the patient should be examined radiographically

My thanks are due to Mr G F Gibberd, under whose care these patients were confined at Queen Charlotte's Maternity Hospital, for permission to publish

A CASE OF RABIES IN SURREY

J Laughlin
M.A, M B Camb
GENERAL PRACTITIONER

D J C Ross
M.R C S

LATE HOUSE PHYSICIAN, REDHILL COUNTY HOSPITAL, SURREY

Rabies is rare in this country, it is only seen in people who have become infected in countries where it is endemic and have travelled here during the incubation period In the past ten years two Servicemen have died of rabies in this country; the last civilian to die of rabies did so in 1911 Increased travel, particularly by air, may well raise the incidence of rabies here

Case-report

A man, aged 32, a bulldozer driver who had last been seen in March, 1954, with subdeltoid bursitis returned from Pakistan on April 27, 1955 He had been feverish on May 6 with a distaste for drink since May 7 He collapsed on May 9 and was behaving irrationally When seen at 3 15 P M he was sitting up in bed, was breathing rapidly, and sweating profusely He complained chiefly of a feeling of heaviness on his chest and inability to drink water or any other fluid for the past twenty four hours

On examination his temperature was 97°F, pulse rate 130, and respirations 60 a minute His tongue was coated and dry, and his throat red, with white viscid sputum round the fauces His pharynx and sclera were anæsthetic to touch When he was asked to breathe deeply, the tachypnœa ceased A few scattered rhonchi were found in his chest, and he had a loose cough He was given a capsule of 'Tuinal' gr 3, which he preferred to swallow dry Asked to drink some milk he became apprehensive, and his terror increased as the milk approached his mouth He took a mouthful and spat it out, his face and neck went into general spasm, the tachypnœa began again, and he complained of heaviness on the chest The tachypnœa ceased when he was told it was unnecessary He then remarked that he did not know before that he had such a vivid imagination He was left to rest -

TABLE I—AGUE COUNTY OF ESSEX, 1871–90
(REGISTRAR GENERAL 1918)

Deaths	Males	Females	Total
Number			
1871–80	38	24	62
1881–90	17	11	28
Rate per million			
1871–80	15 3	9 7	
1881–90	5 2	3 3	

saying in those parts that no young husband down on the marshes need despair if he fell too quickly out of love with his bride Provided she had come from some other part of the county, she was almost certain to die within the twelvemonth

The immunity of the indigenous male to one strain of the benign tertian parasite, the likely basis of this saying, was first demonstrated by the late Colonel S P James in 1924 He also showed that this resistance broke down when the individual was inoculated with another species or strain

There was a remarkable drop in the incidence of malaria during the last quarter of the 19th century, before the transmission cycle of malaria was understood, and therefore before any scientific attempts at malaria control could be made In Essex the number of deaths and death-rate from ague was more than halved between 1870 and 1890 (see table I) (Registrar-General 1918)

Her Majesty's Inspector of the School Board in 1874 described the Isle of Grain district in Kent as low-lying, aguish, and unhealthy, where no one would live if they could help it, and as many as 75% of the population of that area had attacks of ague in 1876 (Burnett 1906) The changing of the garrison at Tilbury fort every six months because of malaria was discontinued, about 1880, and Burnett said that by 1895 "the enemy [malaria] is subdued, for his victims are few, and there is not a more healthy place round the English coast, though what has induced the change it is not easy to determine" The answer is probably found in the history of a man called Henry Pye who became a farmer and took up residence on the Hoo peninsula in 1845 (Arnold 1947)

When he arrived, Hoo peninsula was a backward, poverty-stricken corner of an otherwise rich farming county Arnold describes Pye as "tough, enterprising, self opinionated, stubborn, progressive, outspoken, kindhearted, with a zest for work and sport" He owned one farm, but seems to have acted as manager for several He was a pioneer of mechanisation, owning and operating steam ploughs and steam thrashing tackle He drained the land he farmed, and cleaned the ditches and river outlets on the marsh He was known to keep a stock of quinine for his workers and their families When Pye died in 1909, malaria was rare in the Hoo community

These social economic advances, which Henry Pye symbolised were undoubtedly the main cause of the decline in malaria at that time (James 1929)

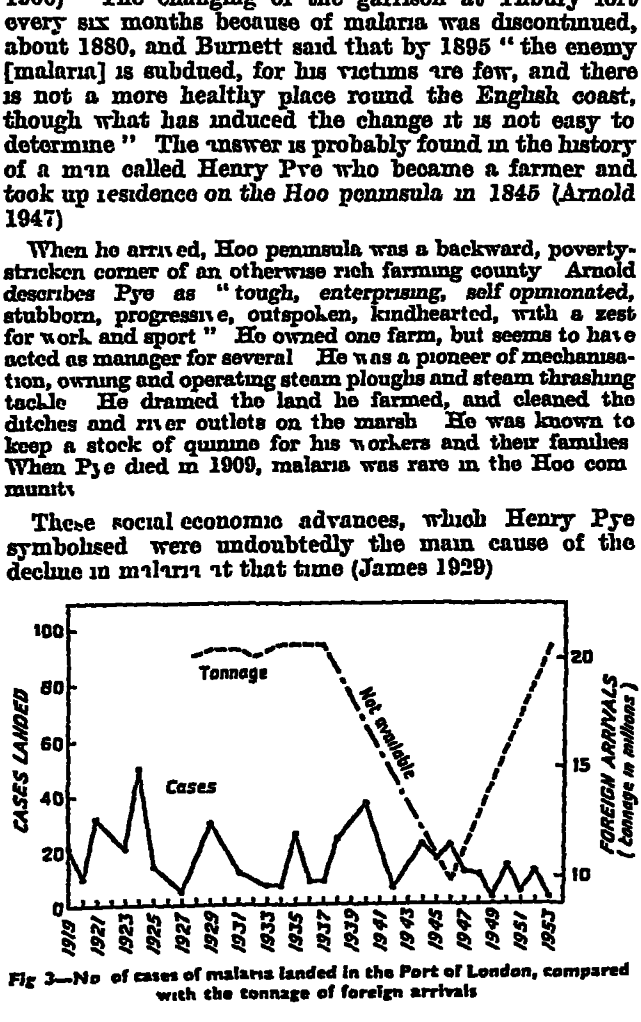

Fig 3—No of cases of malaria landed in the Port of London, compared with the tonnage of foreign arrivals

The causal parasite and the mode of transmission of malaria were first discovered at the very end of the 19th century Patrick Manson first demonstrated the life cycle of the *Filaria bancrofti* in the *Culex fatigans* mosquito in 1879, and this almost coincided with the microscopic recognition of the true parasite of malaria by Laveran, a French army surgeon stationed in Algiers In 1897 Ross, working under the inspiration and guidance of Manson, demonstrated the oöcysts on the stomach wall of *Anopheles stephensi*, and described the transmission cycle of malaria

Many years passed, and the 1914–18 war intervened before the results of these studies could be applied in effective mosquito control measures

World War I

There was an increase in the volume of shipping from tropical Africa because of the war, and many members of the crews of ships arriving at the Port of London from Dakar during the late summer of 1917 were found to be infected with the malignant tertian parasite The medical officer of health for the Port of London requested the local Government Board to take appropriate action in connection with the Port of Dakar, and he told all steamship companies how malaria can be controlled by quinine prophylactically and therapeutically (Willoughby 1918) In his annual report for 1919 there appear for the first time details of shipping arriving in London from malarial ports, together with local Government Board instructions that all passengers and crew who might be incubating malaria should remain under the observation of the medical officer of health at their destination Despite these precautions, the number of cases of malaria seen at the Port of London increased, and Dr Willoughby said in his report for 1923 "the opening out of trade with the West coast of Africa has resulted in malignant tertian malaria in epidemic form on ships" Fig 3 shows that the number of cases of malaria landed in the Port of London has gradually fallen since 1924 except for a slight peak in 1939–40, this decline was most noticeable after 1946, during a period of dramatic increase in the shipping tonnage arriving in the port The task Dr Willoughby started in 1917—the eradication of malaria as an occupational disease among ships' crews—has almost been achieved

TABLE II—CASES OF IMPORTED MALARIA NOTIFIED

Year	No	Year	No
1919	16 955	1944	0

1924	1033	1949	246
1925	823	1950	263
1926	675	1951	177
1927		1952	108
		1953	5[illegible]9

The repatriation of Servicemen during the latter part of World War I was associated with an increase of imported malaria in the country as a whole (Ministry of Health 1919–53, and table II), but only in the Thames estuary did this have a significant effect on the incidence of indigenous malaria Large numbers of persistently relapsing cases were sent home following the severe epidemic of malaria among the troops in Salonika during the summer of 1916, and special camps were erected for them in various parts of the country One camp was situated in the Isle of Sheppey, and many of the men stationed there used to work at Grain Fort (fig 4) At that time there was an Air Force experimental station near Grain village, and many men stationed there mixed with the returned soldiers Many of the infected troops had relapses while in the camps, and as the anopheline density in this area was high it was not surprising that by the summer of 1917 cases of malaria occurred among the civilian population, as well as among men in nearby

The differential diagnosis is from hysteria, tetanus, atropine poisoning, Landry's paralysis, and encephalitis In the present case the condition was immediately recognised as out of the ordinary run of illness, and an intrathoracic disease, psychosis, and hysteria were first considered After the second visit the disease was recognised to be an organic condition, probably of the central nervous system Acquaintance with the patient in health, appreciation that he had insight into his mental state, and the discovery of signs of organic nervous disease helped in reaching this conclusion It was the recognition of the difficulty in swallowing fluids as hydrophobia, and the knowledge that rabies was endemic in Pakistan, which made the correct diagnosis possible

After admission to hospital hysteria was considered a possibility owing to anæsthesia of the pharynx and sclera and the patient's bizarre behaviour This diagnosis was excluded by the continued pyrexia, the leucocytosis, the rapid deterioration of his condition and early death, which was certified as due to encephalitis pending confirmation of the clinical diagnosis of rabies by laboratory investigation

Conclusion and Summary

A case of rabies, which developed in a man ten days after his return to this country from Pakistan and about two months after the bite, which left no scar, is described

The diagnosis of established rabies is entirely clinical Laboratory tests are only useful in the examination of necropsy material from either the suspected dog or the patient Established rabies is always fatal

Having witnessed the course of this illness, we have no sympathy for those misguided sentimentalists who wish to reduce the quarantine period for dogs entering this country

We wish to thank Dr H A Leggett, physician superintendent, and Dr T N Gledhill, pathologist, of Redhill County Hospital, and Colonel H R Bensted and Dr L A Hatch (who isolated the rabies virus), of the Central Public Health Laboratory, for clinical and pathological data, Dr Cyrus Ive, medical officer of health, for information on the preventive measures to be taken, Mr J S Sheppard, photographer, of the Royal Free Hospital, for the photomicrograph, and Dr Neville Southwell for advice and encouragement in the preparation of the paper

Preliminary Communication

NUTRITIONAL AND INTESTINAL FACTORS AND IRON LOSSES IN THE GENESIS OF TROPICAL ANÆMIAS

ALTHOUGH the nutritional megaloblastic anæmias[1-8] are common in the tropics and subtropics, they are not nearly so common as the hypochromic microcytic iron-deficiency anæmias Especially in the coastal, riverine, and lacustrine areas of Africa, India, and other damp hot regions these hypochromic anæmias are a grave cause of chronic ill health.

The blood shows a mean corpuscular volume (M C V) of 45–65 c µ, with a mean corpuscular hæmoglobin (M C H) of 13–20 µg and a mean corpuscular hæmoglobin content (M C.H C) of 20–28%[3, 9] The bone marrow is erythronormoblastic, and vitamin B_{12} levels in the serum are normal During treatment with iron these anæmias become macrocytic, the M C V rising to 110–150 c µ in about ten to fifteen days, but they do not become megaloblastic

ÆTIOLOGY

These severe microcytic anæmias often occur in areas where the diet contains an adequate amount of iron For this there are at least three possible explanations (1) loss of blood from the gut, caused by intestinal parasites, (2) failure to absorb iron from the gut, and (3) loss of iron in fæces, urine, or sweat

Loss of Blood from the Gut

Although hookworm may play a part in the genesis of the tropical microcytic anæmias, this is probably not a paramount one In Mysore State, which has a very high hookworm prevalence, many people have loads up to 9000 (Dr Patwardhan, Dr Work, Dr Anderson personal communication), but the hæmoglobin level in this State, and in those individuals who have heavy loads, is not significantly different from the level in States which have a lesser incidence or in people who have lighter infestations or none In different places in India we found infestation-rates as low as 8% or as high as 85%, but the prevalence of anæmia, and the average hæmoglobin, were not significantly different

In one centre where the infestation rate was 52%, among 300 adults and children the mean hæmoglobin was 9 4 g per 100 ml in another area, where the infestation rate was 12%, the mean hæmoglobin was 9 0 g Taking only cases that had mean hæmoglobins below 6 0 g, the average hæmoglobin in the worm infested cases was 4 8 g, while in the non infested cases it was 4 9 g

Failure in Absorption of Iron from the Gut

A number of factors affect the absorption of dietary iron—e g, gastric acidity, the presence of reducing substances such as ascorbic acid, soluble phytates in the diet, abnormal calcium/phosphorus ratios, and the solid content of cereal foods[10-14] Variations in iron absorption occur that are independent of anæmia and are closely related to the type of diet

In India and Ceylon the main article of diet is rice, which even when polished has a high phytic phosphorus content[15] Rice is further extremely deficient in calcium, and one of the serious deficiencies in the rice eater's diet is calcium[16] A rough estimate of the daily calcium, phosphorus, and iron intake of the average Indian and Ceylon peasant diet would give about the following calcium 106–200 mg, phosphorus 600–1000 mg, iron 14–28 mg With such a diet 5% or less of the iron would be absorbed, yielding about 0 7–1 4 mg of iron daily In addition, in the riverine, lacustrine, and coastal areas fish is eaten and adds to the phosphorus content of the diet

A common practice among the poorer classes of India and Ceylon is the chewing of betel nut leaves with added lime This yields about the calcium equivalent of 10 oz of milk daily, and the habit may account for the lesser prevalence of anæmia found by Stewart[17] among the beggar samples of his group in Pakistan

to estimate the degree of protection from malarial infection which the presence of domestic animals has given to the human community

World War II

The application during World War II of this knowledge of the *A maculipennis atroparvus* enabled precautions to be taken to avoid a repetition of the 1917–19 epidemic A map was prepared by the Ministry of Health showing the areas where malaria was most likely to be contracted and where the disease was most likely to spread (fig 5) This map contained three areas, and the percentage of cases of indigenous malaria from each area after the 1914–18 war was area A 69, area B, 23, area C, 5, and outside these areas, 3 From these figures it was deduced that, should a malaria problem arise, it would most probably be in area A, and to a lesser extent in area B Copies of this map were sent in 1942 to the directors of hygiene of each of the three fighting Services, and the request was made that, as far as possible, potentially relapsing cases of malaria should not be congregated in areas A or B

Prompt action was taken over every notified indigenous case of malaria during and since World War II the patient's house was visited and a mosquito survey made Patients were usually treated with mepacrine, and the rooms and staircase of the house were sprayed with dicophane (D D T), as were any animal houses which were found to be harbouring large numbers of adult mosquitoes

These precautions were particularly vigorous in Kent or Essex, and the striking absence of a major outbreak of malaria after the late war seems to have justified the measures taken (table III and fig 6)

Recent Industrial Developments

The construction of the Kent Oil Refinery was started in 1950 at Grain, on the very site of the last malaria epidemic in this country The peak construction force of 8000 was the largest ever assembled in this country on any one site, and 2000 of this force were accommodated in a labour camp adjacent to the site A certain proportion of this force were ex-Servicemen or coloured immigrants who had recently been in parts of the world where malaria is endemic, and who might therefore exhibit a relapse parasitæmia This produced a nightly concentration of man power, contrary to the Ministry's war-time recommendations.

A meeting of representatives of the Ministry of Health and local authorities was held in the summer of 1952 on the Isle of Grain to examine the potential risk of an outbreak of malaria which this concentration of men might have created Mr P G Shute (representing the Ministry) demonstrated a large number of *A maculipennis atroparvus* in the camp sleeping quarters, and the meeting recommended that immediate steps should be taken to eliminate the high concentration of mosquitoes in the area of the camp These steps were taken and although we took blood slides from all persons on the site who reported sick with a fever of unknown origin, to my knowledge no malarial parasitæmia was ever found

Floods considerably damaged the sea wall around Grain in 1953, and reconstruction work resulted in many burrow pits and other small collections of brackish water being left inside the wall Larvæ of *A maculipennis atroparvus* were still being found in gravel pits near Grain village early in the summer of that year, and some anxiety was felt because these potential mosquito breeding grounds were close to the jetties at which many tankers from the Middle East arrived Frequent complaints by refinery personnel of being bitten at night warned us that mosquitoes were about in no small numbers

This uncertain presence of a malarial hazard made me request a second meeting in September, 1954, attended by representatives of local authorities, Service medical representatives, and other specialists, including Prof G Macdonald of the London School of Hygiene and Tropical Medicine The following recommendation received unanimous approval "The meeting, after having considered the history of the incidence of anopheline and culicine mosquito infestation locally, and elsewhere in the United Kingdom, is satisfied that there still exists a heavy incidence of mosquitoes in the Isle of Grain. This infestation, in addition to creating a serious nuisance, makes possible the transmission of malaria in changed circumstances now existing The meeting, therefore, strongly recommends that adequate measures should be undertaken to control the breeding of mosquitoes in the Isle of Grain, and is satisfied that this could be achieved at a reasonable cost" And while we attempt to implement these recommendations, we are a little relieved by the fact that no case of indigenous malaria has been reported.

Conclusion

Perhaps the ghost of malaria in the Thames area has been finally laid Malaria has fought a losing battle, first with the social and economic advances of the late 19th century, and later with scientific attacks against its lines of communication It is unlikely that imported *malaria will ever again succeed in reproducing the 1917* epidemic, and all that remains is the nuisance of mosquito bites

I wish to thank Mr R J Marsh and Mr E N Moore, the librarians of Rochester and Gravesend, for their assistance and also Mr P G Shute, assistant director of the Malaria Reference Laboratory, Epsom, for his technical advice I would like to acknowledge the ready assistance given me by many medical officers of health and general practitioners in Kent and Essex I also thank Dr J Greenwood Wilson medical officer of health for the Port of London, and Dr S D McClean, chief medical officer of the British Petroleum Company Ltd, for reading this paper, and Mr C S Cleverly, general manager of Kent Oil Refinery Ltd, for permitting me to publish it

Statistics for England and Wales

Provisional death-rates from cancer, tuberculosis, and maternal mortality in England and Wales in 1955 have been announced by the Registrar-General[1]

Cancer —The death rate for all forms of cancer was 2252 per million population for men, and 1873 for women, the 1954 figures were 2223 and 1861 The rate for cancer of the lung and bronchus increased in men from 657 per million in 1954 to 693 in 1955, and in women from 102 per million in 1954 to 106 in 1955 Of the deaths from cancer in males 31% were certified as due to cancer of the lung and bronchus, of the deaths from cancer in women only 6% were so certified

Tuberculosis —The provisional death rate from respiratory tuberculosis in 1955 was 131 per million—a decrease of 18% compared with the previous year The death rate from other forms of tuberculosis was 15 per million, compared with 19 in 1954

Maternal causes —The provisional rate for maternal mortality (including abortion) was 0 64 per 1000 live and still births —the lowest ever recorded

The Registrar-General estimates,[2] on certain stated assumptions, that the total population of England and Wales will increase from 44 023,000 as at mid 1955 to 45,580,000 in 1965, 46,304,000 in 1975, and 46,690,000 in 1985, declining to 46,328,000 in 1995

Reviews of Books

Essentials of Forensic Medicine

C J POLSON, F R C P, professor of forensic medicine, University of Leeds London English Universities Press 1955 Pp 561 30*s*

TEXTBOOKS on the specialties of medicine fall into two categories, the "shorter" and the "much longer" The former guide the student and refresh the practitioner, the latter are books of reference for the expert—and, in legal medicine, for those who want to test the expert's knowledge To expect both in one volume is asking too much, and Professor Polson has plainly set out to enjoy writing at length on a subject he evidently revels in, exploring the literature and collecting what Montaigne would have called *un amas de fleurs etrangeres* It is superbly done, for he writes well, lucidly, and sanely, weaving the vivid and the more mundane chapters of forensic medicine, medical ethics, law and insanity into a comprehensive whole that is both informative and readable The book is no short guide to the subject for the student, but it will delight the specialist who cannot summon Professor Polson's enthusiasm for research into the literature The absence of pictures is a break with tradition, made deliberately, so as to "focus attention on the text" A toxicology on similar lines is to follow

The Clinical Approach in Medical Practice

G E BEAUMONT, D M F R C P, honorary consultant physician, Middlesex Hospital London J & A Churchill 1956 Pp 469 45*s*

THIS is a sequel to Dr Beaumont's *Applied Medicine*, and it follows similar lines The emphasis throughout is on practical clinical matters, and both this book and its predecessor show clearly how a skilled and intelligent physician's mind works when he is faced with a difficult diagnostic problem

In one section he describes some interesting cases he has met, and in another he and a group of pupils discuss, by the method of question and answer, the differential diagnosis of other cases In the case descriptions Dr Beaumont amply proves how repaying is care in history-taking and bedside examination In the question and answer demonstrations he explodes with wit and erudition (some of his pupils are remarkably well informed, too) and the joint result is both instructive and diverting There are two new features a section describing in detail the psychological reactions of some tuberculous patients to their disease, and a short philosophic excursion into the ethics of prolonging life in advanced heart-disease Dr Beaumont seems less at home with such emotional matters, and this part of the book is rather dull, but the rest is more entertaining than many a novel

Splenin A in Rheumatic Fever

The testing of splenin A as an anti-inflammatory agent ALVIN F COBURN, M D, LUCILE V MOORE, M D, JUDITH WOOD, M D, MARY ROBERTS, R N, Rheumatic Fever Research Institute, Northwestern University Medical School, Chicago, Ill Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 86 27*s* 6*d*

IN the modern therapeutic arena a favourite battle with the crowd involves Allergy, and particularly the chimera Rheumatic Allergy Here comes a dark horse in the trampled wake of the giants Corticotrophin and Cortisone, challenging perhaps the most elusive champion of all, Rheumatic Fever Is Splenin A a worthy opponent? On its form it will do As Ungar described it, splenin A is a product of the spleen which decreases capillary permeability, increases capillary resistance, and shortens bleeding-time Like corticotrophin and cortisone it increases the antifibrinolytic activity of guineapig serum, but unlike these hormones has a similar action in splenectomised animals Moreover, it inhibits anaphylactic arthritis in the guineapig—and is not hypersensitivity its opponents' Achilles heel?

How will the issue be judged? Not by therapeutic trial, the challenger, unfortunately, is as yet too meagre of substance By clinical impression then, and a consensus of opinion about anti-inflammatory effect The skirmishing begins, the contestants are hidden in clouds of dust The challenger sometimes seems to be on top, but alas! when the air clears, the champion looks the fitter of the two, and the laurels are still firmly on his brow What does the crowd think? It has been offered poor material for judgment, so it very sensibly keeps its thumb in its fist, and refuses to consider its verdict

A Hundred Years of Nursing

SIR ZACHARY COPE London Heinemann Medical Books 1955 Pp 144 10*s* 6*d*

THE main part of Sir Zachary Cope's interesting book describes the history of nursing at St Mary's Hospital, Paddington, since it was opened in 1851, but in a first chapter he gives a short account of the general history of nursing during the same period, which shows the striking changes which have taken place

In 1860 the matron asked if a gratuity might be given to a sister who was leaving after seven years' service The board recommended that she be given £3 to pay her travelling expenses The matron herself was dealt with rather shabbily Her salary remained at £50 per annum for twelve years, after which an increase of £10 a year was granted And out of her meagre salary £12 had to be spent on washing

James Parkinson 1755-1824

Editor MACDONALD CRITCHLEY, M D, F R C P London Macmillan 1955 Pp 268 15*s*

To mark the bicentenary of Parkinson's birth four papers dealing with Parkinson's disease have been attractively published The book includes the original Essay on the Shaking Palsy There is also an introduction by the editor, a biographical essay by Dr W H McMenemey, an account of the pathology of Parkinson's disease by Dr J G Greenfield, and a clinical analysis of the paralysis-agitans syndrome by Sir Francis Walshe

Parkinson led an exciting life He was something of a political revolutionary but escaped the fate of transportation and imprisonment which befell several of his associates Two of his tracts were entitled Revolution without Bloodshed or Reformation preferable to Revolt (1794), and Whilst the Honest Poor are Wanting Bread (1795) His papers on medical subjects included Hints for the Improvement of Trusses (1802), Some Accounts of the Effects of Lightning (1789), and one of the earliest descriptions of a Case of Diseased Appendix Vermiformis (1816) He emerges as a competent and keenly observant surburban practitioner, and an eccentric But for all that he was an engaging and likeable character, modest, unassuming, and warm hearted His famous essay is a great rarity, but it is very profitable reading How effective are the words with which Parkinson opened "Involuntary tremulous motion, with lessened muscular power, in parts not in action and even when supported, with a propensity to bend the trunk forwards, and to pass from a walking to a running pace, the senses and intellects being uninjured"

The editor and his collaborators have done well in republishing and adorning this classical piece of medical writing

Airborne Contagion and Air Hygiene

WILLIAM FIRTH WELLS, PH D, laboratory for the study of airborne infection, University of Pennsylvania School of Medicine Cambridge Mass Harvard University Press London Oxford University Press 1955 Pp 423 48*s*

FOR more than twenty years Dr Wells has been engaged on the problems of airborne infection Much of his published work has been highly technical, and it was therefore encouraging to read in the preface to this book that "much of the original work had . to be revalued, and significance, only implicit in published papers, made explicit in the book." But he has not entirely succeeded in this last purpose

In the first part, Dr Wells describes, in physical and mathematical terms, the formation and behaviour of respiratory droplets He examines the merits of various devices used for the bacteriological analysis of air and describes the influence of ventilation and ultraviolet irradiation on airborne organisms The first part of the book ends with a consideration of the factors influencing penetration of infected particles into the lung clinical staff of the teaching hospital in collaboration with preclinical teachers

The college also wishes to point out that the very necessary integration between preclinical and clinical studies cannot be achieved unless the character of the examinations which separate them is altered

Clinical Studies

During this period a thorough training in clinical methods and clinical thought has to be combined with increasing acquisition of knowledge of disease and the care of the sick The student must learn how to use clinical techniques, he must learn how to interpret signs and symptoms of disease in terms of disordered structure and function, and he must gain a working knowledge not only of the causes and effects of disease but also of the requirements of physical and mental health All the time, factual information has to be kept in balance with clinical facility

Such studies fall naturally into three stages (1) a period devoted largely to methods of examination, both clinical and ancillary, (2) a period in which clinical practice is associated with the more academic study of disease processes (clinical pathology, morbid anatomy, and environmental pathology), and (3) a period of practice with increasing responsibility but still under supervision During this last stage much may be gained by arranging for the student to spend some months wholly or mainly in any department chosen by himself, for both his interest and his understanding will be stimulated by working in an atmosphere of progress and research In addition, teaching authorities will no doubt wish their curricula to be sufficiently variable to allow students of unusual aptitude and ability to avail themselves of opportunities for special experience

Throughout the clinical period, the fundamental unity of medicine should be emphasised, and the barriers between departments must not be such as to prevent the student from moving from one to another—either in person or in thought

As to how the time of the clinical curriculum should be divided between different branches of medicine and its specialties, the college hopes that the General Medical Council will make no formal recommendation, since it is preferable that each school should work out the kind of curriculum best suited to its own character and capacities In general, however, it may be stated that, though clinical principles can be learnt in any clinical department if the teacher has skill in teaching them, the early training in method is ordinarily best given in departments of general medicine and general surgery, and then strengthened in selected special departments

Provisional-registration Year

A year of responsible practice under supervision will normally complete the doctor's basic education by fitting him to take full responsibility for the care of patients, even though at first he is unlikely to practise independently Teaching authorities will note, however, that this year following qualification provides them with an opportunity to assess every student's clinical ability more satisfactorily than has hitherto been possible Like the learner driver of a motor vehicle, the student is called upon to display his trustworthiness, and, if he fails to do so, a further period of work under supervision ought to be prescribed Senior members of the medical profession accepting responsibility for this final stage of basic medical education should recognise its importance both to the young doctor and to the public, and should not regard their final certificate as a formality to be fulfilled even if their pupil's performance has been below the standard they expect

Length of Curriculum

The scope and possibilities of medicine have so much enlarged that its efficient practice is in many respects becoming harder The period at present assigned to the preclinical and clinical studies preceding qualification is a minimum of five years, and this minimum cannot be reduced until the council are satisfied, by observation, that a basic medical education need not last so long A comprehensive vocational training would clearly have to last much longer

Because of the importance of preserving the student's freshness of mind during this protracted period, care must be taken to give him sufficient holidays

Reconsideration of Curricula

The difficulty of judging the relative merits of different educational methods makes it desirable to permit, and even promote, experiments in medical education By their diversity (which the General Medical Council have always striven to maintain), and also by their stability, medical schools in this country are well fitted to explore fresh possibilities for the teaching of the future doctor In refraining from detailed recommendations, the council would give much-needed encouragement to teaching authorities to reconsider their curricula as a whole, in the knowledge that, within wide limits, variation will be permissible Equal freedom to differ on method could perhaps be accorded to separate medical schools governed by a single teaching authority

A curriculum must be largely an expression of the particular features and facilities of each medical school and in the final analysis its success will depend not on regulations but on the teachers' attitude of mind and the facilities at their disposal The subjects will often matter less than the circumstances in which they are taught

In each school there must be enough teachers able to give the time required for the realisation of their concept of teaching, and it is the responsibility of the school to build a teaching team capable of carrying into effect its particular scheme of education In such arrangements it should be borne in mind that full use of the valuable clinical teachers who work both in teaching hospitals and in regional hospitals is impossible unless they are enabled to spend some sessions at the teaching hospital additional to those arranged for the care of the patients in their charge

Specialisation and the advent of the National Health Service have substantially altered the clinical facilities offered to students by the teaching hospitals Already different patterns of teaching hospital have emerged and, though the relative merits of these patterns cannot yet be evaluated, a duty rests on each board of governors to see that the clinical facilities for its students are as good as it can make them

To this end some teaching hospitals and universities may feel it necessary to request alterations in the arrangement of the hospital service, and in such cases the council should be willing to offer advice and, where appropriate, support Students in their clinical period could profit by experience of medical practice outside hospital, under conditions within the immediate control of their medical school * and the creation of facilities of this kind—e g, university health centres—exemplifies not only the need for medical schools to break new ground but also the problems they will face in so doing The college hopes that in the solution of such problems the council will wish to help

Just as the imposition of a single curriculum would stifle the initiative of the medical schools, so uniformity of the curriculum in any one medical school can stifle the initiative and ignore the particular requirements of particular students To subject all students to a common course in which knowledge is acquired passively, from instruction, is a partial confession of failure Instead

---

* A brief period as observer in a general practice may also be useful in showing the student what sort of work general practitioners do But in the college's view such observation is supplementary to basic medical education and not an essential part of it

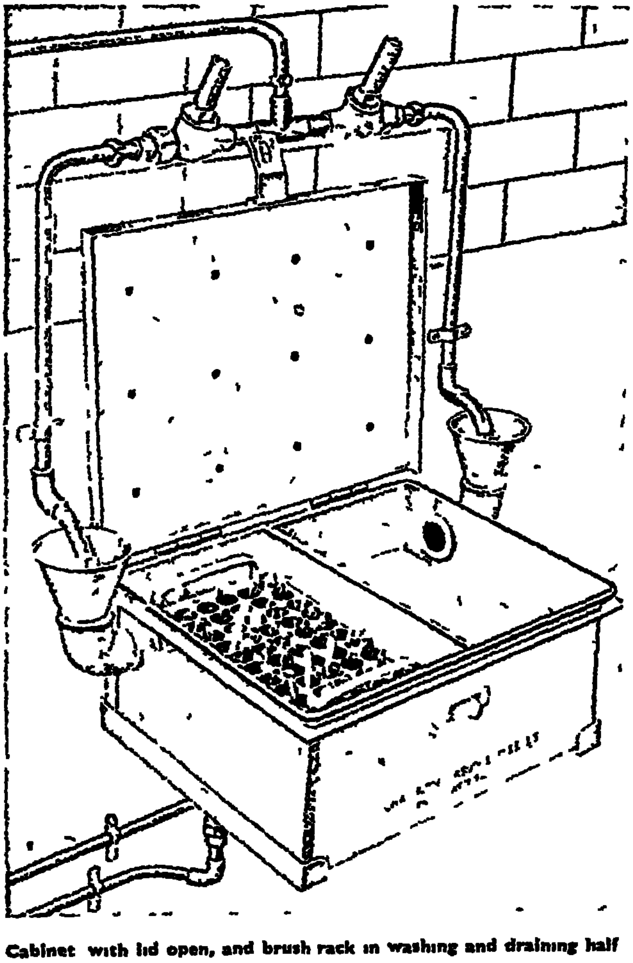
cabinet can be locked Both halves of the tank can be drained and are connected to inlet water-pipes To prevent contamination of the inlet water pipes, these are not connected directly with the water mains The inlet pipe on the half of the tank occupied by the sterilising solution allows this half to be well rinsed when the solution is changed, there is sometimes a slight deposit at the end of two or three days The taps for the inlet and drainage pipes are operated by a removable key, which is in the possession of the charge nurse

The brushes are collected from the patients and placed in a stainless steel rack similar to a test tube stand, which has two horizontal plates perforated with 60 holes The rack and brushes are then thoroughly rinsed with tap water to remove debris and placed in the half of the tank containing the 1 in 200 solution of monochlorisothymol for two hours, after which they are placed in the half of the tank containing tap water After one hour, the water is drained off and the brushes left to dry until required



Cabinet with lid open, and brush rack in washing and draining half

The solution of monochlorisothymol has been found to be effective in the cabinet for three days, after which time there was slight contamination Because the substance is comparatively cheap, a fresh supply of solution is issued on Mondays, Thursdays, and Saturdays

CONCLUSION

It is highly desirable that oral hygiene should be observed in all hospitals, and this method of sterilising and storing toothbrushes is simple, clean, and effective, as well as being economical in cost and labour.

I wish to thank Dr A H Wilson, medical superintendent of Meanwood Park Hospital, for his help in the preparation of this article

In England Now

A Running Commentary by Peripatetic Correspondents

In Renaissance Italy physicians and artists shared the shelter of the same guild, and the great medical teachers studied anatomy alongside the Leonardos of the day The past centuries—economic evolution, if you wish—have dissolved this intimate and happy association The doctor has drifted from art to the sterner shores of science, and the artist has abandoned the study of Nature and succumbed to his own surrealistic vision Yet even now doctors turn to art for release from what Osler called "the malign influence of the routine" The members of the Medical Art Society[1] do not form a "school," but they do share one quality—the holiday spirit They are happy (sometimes happy-go-lucky), warm, spontaneous, often exuberant They are escapists, though their escape may be not years in Tahiti but a fortnight in Provence, or an hour at a window looking down on Regent's Park

Even R A Beaver's beautifully quiet *Queen Anne Street* is a Sunday townscape H Elliott-Blake's *Las Aldea de Miel* is inspired, like all good landscapes, by familiarity, not by strangeness, the houses, the chalky soil, the gray, windy sky have the intimacy of experience that made Corot and Constable so evocative W G Scott Brown's cool, delicate tones are closer to the late French impressionists, but it is his own power to create air and light, not the muffled footsteps in the sand of Degas and Berthe Morisot, that makes his *On the Beach* one of the most memorable pictures of the exhibition P. Tuttnauer's *The Beach* is a brave effort at *pointillisme*—which miraculously succeeds, it is not as monumental as Seurat but quite as sparkling B U Coffey's *Crucifixion* is Blakeian in vision (but he should expurgate Salvador Dali), and R T Payne's three pictures are lone representatives of the truly contemporary school *Phoenix* is his best

Water colours have many attractions for the amateur—they are clean, orderly (as those things go), cheap, and, it seems, so absurdly simple No wonder that many a beginner who recklessly takes the plunge, gets swirled about in a pool of transparent washes, tints, and shadings and emerges spluttering—or reaching for oils with which he can start, stop, scrape, and cover over at his heart's and eye's delight But happy are those who survive, and remain restfully afloat in the medium and twice happy those who, like B A Brooke, learn to command it His *House of Usher* is water colour at its most romantic and its most brilliant the challenge of Poe gallantly met But in a quieter vein there are many admirable water colours here G H Rose uses the damp rawness of the paper to make his *Miller's Lane* hauntingly bleak, in a lucky moment T Holmes Sellors catches the breaking clouds of a summer storm, and Mary Wiles the fading radiance and silvery grace of what can only be Bruges Henry Wilson's *Harvest Time near Ely*, K Shirley Smith's *A Corner in the Meadow*, Constance Appleton's *Ullapool*, and Sir Philip Manson Bahr's *A Sussex Lane* are a random selection of others which pleased Liverpool and the North are well represented by a handful of pictures T N A Jeffcoate's luminous *Spring* and C Wells's *Treaddur Bay* are most attractive

The portraits are few but excellent Josephine Roth's drawings are character studies of rare distinction and W G Sears's *Heather* is expressive Of the sculptures G Konstam's *Boy with a Parrot* is delightful and technically accomplished J Rostowski's squinting terracotta boy has infinite charm, but his *Split Personality* and *Obsession* suggest that schizophrenics are no more suited to sculpture than unknown political prisoners

This is not to say that medical subjects are unsuited to art—do not our nurses outshine the dancers of the Paris Opera? But for the moment Art remains on the periphery, a whim in the holiday mood, while Science jealously guards the gates

* * *

The paraplegic in our ward needed a new self-propelling chair and, to set the wheels in motion, the official request form was properly signed, countersigned, sealed, and sent off with the blessings of even the hospital secretary In the good old days, when a spade was a spade, a chair was also a chair, but such simple considerations are no longer

Medical Evidence

How can the Law best obtain expert medical evidence? The normal method both in this country and the United States is for the opposing parties in a dispute to call their own medical witnesses these witnesses are then cross-examined and, if they disagree, it is for the judge or jury to decide what evidence to accept There are some exceptions occasionally in this country the parties may put in an agreed medical report, in nullity cases the court may ask (though it does not compel) either party to submit to medical examination by an impartial doctor, and in cases under the National Insurance Acts, the claimant may also be required to undergo impartial medical examination All these however, may be regarded as the exceptions which prove the rule

Many people feel that the usual methods of giving medical evidence could be improved[1], and those who seek reform will welcome a report[2] by a special committee of the New York Bar Association on a proposal to use impartial medical testimony in cases of personal injury As some 80% of the cases in the United States trial courts are concerned with injury and involve medical evidence there seem to be good grounds for the claim that "the project is directed at the very core of court operations" The idea was conceived by the judges of the Supreme Court of New York and was put to the test experimentally, first in New York County and later in Bronx County as well, with the cooperation of the local bar associations and medical societies The results were so satisfactory that impartial medical testimony is now a regular part of the operations of the Supreme Court of New York State Under the new arrangement, the judge may, before the trial, order the examination of an injured person by an impartial medical expert Before doing so, he consults counsel for the two sides, but their consent is not necessary In fact, during the two years covered by the report no lawyer registered any sharp objection, indeed, in some cases, the lawyers themselves asked for an impartial expert This step is facilitated and even encouraged by a feature of the American legal system which does not exist in Britain—namely, the pre-trial conference This conference enables the judge and the lawyers for both sides to explore the issues in the case and the possibilities of a settlement, the discussions being held in an informal atmosphere, usually some months before trial If the judge orders an examination by an impartial expert, the pre-trial conference is adjourned In making his order, the judge indicates the nature of the medical dispute and the type of specialist who should carry out the examination, occasionally, of course, more than one specialist is needed The actual selection of medical experts is made by a specially constituted "medical record office" from panels drawn up by the local medical societies In due course, the pre-trial conference is resumed when the case will again be discussed in the light of the expert findings

From the incomplete statistics available it seems that well over a quarter of the cases referred in this way to impartial experts were settled at or before the resumed pre trial conference of the remainder, a substantial number were settled after the resumed conference but before trial In all, over half the cases seem to have been settled before trial In considering these statistics, it must be borne in mind that the possibilities of a settlement do not always depend on the medical evidence Even if the medical evidence is accepted by both parties, there may be other issues for trial—for example, the alleged negligence of the defendant and contributory negligence on the part of the plaintiff Moreover, even where there is agreement on the nature of the injuries there remains the question of damages But, of course, there will always be cases in which there is an honest difference of opinion between the medical experts If the cas goes to trial, the impartial expert may be called t give evidence at the request either of counsel or judge. If so called, he will be subject to cross-exan nation and either party may call their own exper But the effective scope of cross-examination and tone in which it is conducted are different impartial expert will have been chosen from a panel drawn up by the medical societies and he will be a recognised specialist in his field His impartiality is emphasised by the fact that he is paid out of special funds and not by the contesting parties Indeed, such a standing has been achieved by the impartial expert that a few American judges and lawyers are beginning to fear that his importance is over-emphasised and that his word is too readily treated as gospel

Some other results of the New York project are worth noting Often plaintiffs have been persuaded to abandon inflated claims for damages, but in other cases the independent medical report has convinced the defendant that the plaintiff's case was well founded Occasionally, examination by a specialist of high standing has strengthened the plaintiff's case by drawing attention to points overlooked by his own doctor The new method of taking evidence once again demonstrated that many doctors were slow to use radiological and other diagnostic techniques, and the New York Bar Association think that the result may be an improvement in the diagnosis of injuries " it is likely that the project will not only help in informing judges and juries of what doctors know (thus improving the process of legal fact-finding), but will go one step further and help the doctors themselves in discovering the truth (thus improving the basic process of medical fact-finding)"

The success of the project immediately raises the question whether a similar scheme could usefully be introduced in this country There can be little doubt that it would be of great value in the pre-trial stages Although many actions arising out of physical injury are already settled before trial, the use of independent medical reports would provide a more satisfactory basis for settlements The American lawyers, worked out their plan with the pre-trial conference in mind, but the fact that British law does not provide for this conference need not preclude the introduction of a similar scheme here Our courts have a highly developed system of pre-trial instructions, operating through the jurisdicgrowing tyranny of the large organisation which claims the exclusive right to speak for a particular group or calling, and to control the actions of its members It is therefore vital that the Royal Colleges and Corporations should remain free to express independent views, and to act or withhold action in any field of medicine including its relations with the State

[2] mpartial Medical Testimony a Report by a Special Committee of the Association of the Bar of th City of New York New York and London Macmillan P 6d

But I know that many members of the B M.A fully recognise this, and realise that any attempt by the Association to dominate rather than collaborate would not only fail, but seriously injure the status of medicine in this country Indeed the B M A Council in its report states that it "is satisfied that the decision to establish the Joint Committee was a right and wise one The committee has worked harmoniously and effectively" For that very reason many will share my regret at this attack upon the Royal College of Physicians, which must make it more difficult to maintain that cooperation in the Joint Committee and between the Joint Committee and the General Medical Services Committee, which some of us have worked hard to achieve

The Royal College of Physicians,
London, S W 1

W RUSSELL BRAIN

DEHYDRATION FROM TUBE-FEEDING

SIR,—Prolonged tube feeding requires a liquid diet of adequate calorie and protein content, some of the formulæ even provide what would appear to be an excess of protein (140 g or more daily) The production of osmotically active substances from one such preparation ('Complan') can be calculated as at least 1100 milliosmols per day, and the amount of water given with it, following the makers' instructions, may be as little as 1900 ml It seemed to us that this might require an osmotic performance beyond the capacity of the kidneys of some patients

In order to define the necessary osmolarity, we have given complan as a 20% solution to two healthy subjects Although neither subject became thirsty, and in neither did the plasma-sodium level rise, the urine osmolarity, calculated as 2 $(Na + K + NH_4)$ + urea, rose to 940 and 1120 milliosmols per litre, *this level might not be attained in patients* with impaired renal function Moreover the blood urea level rose in one subject from 33 to 63 mg per 100 ml in four days, and in the other from 28 to 61 mg per 100 ml in three days Both subjects became constipated on the low-residue diet

We do not of course, believe that blood urea levels of this order do any harm, but we record this finding to prevent such levels under similar circumstances being ascribed to renal insufficiency (the urea clearance in both subjects was normal) We would also question the need for so high a protein intake, and suggest that such regimes are potentially dehydrating Water depletion on high-protein diets has been reported by Engel and Jaeger,[1] and we have ourselves seen a patient whose plasma sodium level rose to 160 m eq per litre on this type of regime

We would question the need for régimes so high in protein content for tube feeding, especially for comatose patients who cannot complain of thirst and so draw attention to their dehydration As a practical measure, we would recommend giving smaller amounts of these feeds, making up the caloric deficit with glucose, and giving an ample allowance of water—sufficient to prevent thirst in the conscious patient

FRESH MILK OR TABLETS ?

SIR —You mention (Feb 25) two difficulties in the supply of school milk—that of supplying remote schools with fresh milk, and the reluctance of milk suppliers to allow discount or to agree to competitive tenders

The opposition by the milk trade to competitive ten and the *formation of price rings* are regrettable, parti in towns where discount could be given without detr the trader's profit The supply of milk to village scho often less profitable to the trader, who has to supply a number of one third pint bottles and transport them l distances by a certain time each morning The probl greatest if the local authority stands out for a paste supply, which often means inducing a trader from a town undertake a long country round If traders tender for schools at the normal retail price of milk, the authority be receiving fair treatment, indeed some traders have helpful in supplying remote schools at little profit bec they recognise the importance of school milk to the comm and it would be unfortunate if they felt themselves to b included in the criticisms made by the Committee on Pu Accounts, who appear, as is so often the case with bod *reviewing administrative arrangements*, to be thinking ma in terms of towns

It would be even more unfortunate if anything we done to make supplies of pasteurised milk to rural scho more difficult to obtain than they already are I can believe that tablets, however alluring the fruit flavo are an entirely satisfactory substitute

AFTER MENINGITIS

SIR,—*In your annotation of March 24* you expr concern at the tragic sequelæ of meningitis in childre and quote Desmit,[1] who, in the Hague, had a mortalit of 7%, and a failure rate (died or left with gross defect *of 22% in 114 cases*

It must come as a surprise to learn that, in this countr the over all mortality from meningococcal meningitis is 20 rising to 25% in the 0–4 age group[2] In the first year of l alone 550 deaths were attributed to meningococcal meningi in the years 1946–54 The fatality rate during this time h remained persistently high Judging from Desmit's experien it is not unreasonable to suggest that, with a mortality of 20 more than half the cases of meningitis in this countr eith die or are left with gross defects

With the present number of powerful antibiotic treatment should be satisfactory Early and accura diagnosis is essential It is possible that antibiotic a a double edged weapon A sequence of events no uncommon is for a practitioner to be called to see a chi in the early stages of a meningococcal infection, when th symptoms typically suggest an infection of the upp respiratory tract Oral penicillin is prescribed It absorption is irregular, and its passage through the bloo brain barrier in adequate amounts is doubtful Th infection is not killed, but smoulders on By the time th child reaches hospital permanent cerebral damage ma have occurred The classical picture of meningitis ma no longer be apparent, and further delay may occ before a diagnosis is made and adequate treatment give *It is customary for a lumbar puncture to be* carried ou only if there is a definite indication It should be a golde rule for a lumbar puncture to be done on all urge pædiatric admissions, *unless there is a definite* indicatio *against* (i e , if some other diagnosis is obvious) If th was done, unsuspected cases of meningitis would come t light, and delay be avoided

It is also essential that suspected cases of meningit should be admitted only to units which have a twent four hour pathological service, and where the cerebr spinal fluid can be examined, the organism identifie and the appropriate treatment carried out witho delay Meningitis is just as much an *emergency* as acu appendicitis, and a pathological laboratory is as essenti to the one as an operating theatre to the other No o would consider admitting a patient with acute appendici to a hospital without a theatre, yet there must be ma to a crush fracture caused by impaction against the glenoid margin at the moment of dislocation, or possibly to secondary flattening from repeated episodes In some series as few as 20% of cases showed this defect, in others they all had it This variation depended to some extent on the care with which the defect was looked for In abduction and external rotation this defect engages with the glenoid, and the joint may lose its stability and become dislocated

[1] Desmit E M *Arch Dis Childh* 1955 30 415

[2] Report of the Ministry of Health 1954 part II p 18

Recurrent dislocation has for many years attracted he inventors of new operations Bearing in mind the asic abnormalities, it is not surprising that the only perations that have stood the test of time are those which produce some sort of buttress at the anterior glenoid margin It does not seem to matter much whether this is achieved by reattachment of the avulsed glenoid labrum or capsule or by the use of the tendon of subscapularis (the PUTTI-PLATT operation[6]), fascia lata (GALLIE), bone blocks from free grafts or a displaced coracoid process, or scar tissue (HIPPOCRATES used the cautery for this purpose) Simply to use the anterior approach ensures the formation of some scar tissue just where it is needed Those who believe in the importance of the humeral defect insist hat some loss of external rotation must be accepted o as to prevent the defect reaching the glenoid, and hat without this disability the patient is still in danger of recurrence While many patients regain a full range of movement after these operations, most are left with slight loss of abduction and considerable loss of external rotation DU TOIT and ROUX do not believe that this loss is necessary, they fix the avulsed labrum to the glenoid margin with the staples originally introduced by FOUCHE and proceed to remobilise the shoulder immediately after operation They claim that in this way full movement is rapidly regained, the period of postoperative disability is much shortened, and there is no danger of recurrence The use of staples is not without danger, they can pull out, and more than one has had to be removed as a loose body in the shoulder-joint It is however, a simple method which may appeal to those who have found that the suture work involved in any repair at the margin of the glenoid is not quite so easy as some advocates of this operation maintain It will still be some years before we can judge whether some restriction of movement must really be endured in order to guard against recurrence But however the repair work is done, most recurrences are due either to major violence that might well dislocate a normal joint or to technical faults that only greater care and experience will eradicate

Vomiting Sickness in Jamaica

FOR more than fifty years an often rapidly fatal illness called 'vomiting sickness' has been known in Jamaica Most of its victims are children between the ages of two and ten years, and they are always from the poorly nourished peasant class The onset is said to be abrupt, usually but not always with vomiting. and there is invariably a feeling of intense weakness Prostration soon follows, but there is no fever and no diarrhœa Recovery may be complete in a few hours, but often, after periods of semi-coma, the child lapses into deep coma, with twitching convulsions, and death

As long ago as 1916, SIR HAROLD SCOTT[1] suggested that the illness was caused by eating the fruit of the ackee tree (*Blighia sapida*) and it has often been called "ackee poisoning" Ackees are a favourite food in Jamaica, but are rarely eaten elsewhere The ackee tree bears handsome bright-red pear-like fruits which split when they are ripe, into three segments Within are three hard seeds, looking like black shiny acorns, each on top of a yellow fleshy arillus about an inch long It is this arillus which is cooked and eaten, it tastes like a fatty variety of roast chestnut, but it is even more appetising But while ackees are freely eaten everywhere in Jamaica, vomiting sickness is confined to a few peasants, mostly children Moreover, vomiting sickness may be sporadic, it may affect a particular family, or it may occasionally be epidemic but then only in the winter months December to March, and in certain localised areas Yet the distribution of ackees is island-wide and crops are eaten in other months Doubt was thus expressed that the ackee was the cause of vomiting sickness, though EVANS and ARNOLD[2] had prepared extracts from it which were toxic to animals Many other plants taken as "bush teas" were incriminated instead BARNETT[3] the Jamaican government's chemist, blamed certain yams which he found to contain, when immature, a toxic glucoside

Some observers even raised doubts about the existence of vomiting sickness as a separate disease they thought the term merely included a wide variety of conditions wrongly diagnosed, and after 1944 the Registrar-General of Jamaica ceased to record it as a cause of death In 1951 however there was an outbreak in the parish of St James (with a population of about 75 000) in which 151 people were affected and 32 died This revived alarm about the condition, and the Jamaican government voted a substantial sum of money for the investigation of the illness by the island's medical department, in collaboration with the University College of the West Indies, the work to be organised by DR CICELY WILLIAMS[4] It was soon apparent that most isolated cases of vomiting sickness had been wrongly diagnosed Then 4 out of 5 children of a family who had apparently been well and active were seen at the new University College Hospital they had had the characteristic abrupt onset of weakness and drowsiness with vomiting, and 2 were dead within a day STUART et al[5] found extreme hypoglycæmia (blood-sugar levels as low as 22 mg per 100 ml were recorded) in each of these 4 children and in 5 others who had the same typical illness This observation established the condition as a true clinical entity and laid the foundation for its logical treatment by prompt and large doses of glucose Biopsy and necropsy[6,7] showed fatty changes in the liver with almost complete absence of glycogen, and glycogen was replaced after successful glucose therapy Since the disease was thought to be due to an unknown ingested toxin which produced temporary enzyme block, probably inhibiting gluconeogenesis, the name "acute toxic hypoglycæmia" was proposed.

On the very important question of "settling down" you seem to suggest that this is largely unnecessary, because modern methods of treatment have shortened the period of hospital treatment I am quite aware of the difficulties of reintegrating the patient mentally or otherwise into the family after a lengthy stay, but I would like to emphasise what appears to be self-evident, though it does not seem so to all psychiatrists—that mental disorders, though sometimes treatable by physical means, are mental They can rarely be overcome in a rush, and certainly no problems of life can be solved by physical treatment

I think it is time that in psychiatry the rôle of the asylum and retreat were acknowledged For some time at least, the best treatment is the retreat, with or without spiritual help from the doctor or priest

TEA IN THE OFFICE

SIR,—Your issue of March 3 has been brought to our attention, with particular reference to "In England Now" and the tea-making equipment to be seen in a hospital general typist's office You may consider that we are oversensitive about this, but when one appreciates the totally inadequate canteen facilities for clerical staff in so many hospitals, the extra time these girls willingly work without recompense, and the lack of limelight which comes their way as compared with that shining on other hospital workers, the remarks printed can only be considered as an abuse of the restricted space accorded to you by the discontented typographers that week

Kingston Hospital, Surrey

P DIGNALL

SPONTANEOUS HYPOPARATHYROIDISM WITH MEGALOBLASTIC ANÆMIA

SIR,—The case reported by Dr Hurwitz (Feb 4) would appear to be the second example of this extremely rare combination and not the first as Dr Hurwitz believes An identical case was reported by Reisner and Ellsworth [1] in America

The American case has many features in common with that reported by Hurwitz The age at onset and the sex were the same, and in both girls the physical build was suggestive of pseudohypoparathyroidism although this was proved not to be the correct diagnosis

The American case sheds further light on the nature of the megaloblastic anæmia Unlike the patient of Dr Hurwitz this girl had at no time received any anticonvulsant drugs so phenytoin sodium can be completely excluded as a possible cause Reisner and Ellsworth showed that the anæmia in their patient was unaffected by *oral* vitamin B_{12}, but that the addition of intrinsic factor to the vitamin B_{12} given orally produced a reticulocyte peak of 23 7% after eight days treatment This is presumptive evidence that the patient was lacking in intrinsic factor and was in fact suffering from pernicious anæmia

Manchester

S SHUBERT

UTERINE DYSFUNCTION DURING LABOUR

SIR,—I should like to comment on Dr Cramond's use of an inventory as described in his letter (Jan 28)

The "lie" scale from the Minnesota multiphasic personality inventory was incorporated with 65 other items (whose source was unspecified) and was scored as it is in the M M P I This procedure is of very doubtful validity It is impossible to know in advance the effect of lifting a scale from the context within which it was standardised, the effect might be to distort the scale so that the original scoring standards become inappropriate It seems, then, that Dr Cramond should either regard his inventory as a new test and standardise it anew, or else use the whole M M P I and score the "lie" scale according to Hathaway and McKinley's tables

There is a danger in the latter method, however Hathaway and McKinley standardised the test on Americans Dr Cramond has tested Scottish women, and it is impossible to say whether a test standardised in one country will be valid in another Dr Cramond's results suggest that in this case it is not In two separate investigations a third of his patients had significantly high "lie" scores This is a very high proportion, and one must ask why In view of the large numbers tested, chance can be ruled out as a determining factor This leaves two alternatives first, that Dr Cramond's group was not a normal one but contained a large proportion of women who were mentally ill, and second that the American scoring of the "lie" scale is not applicable to the answers given by Scottish women The second explanation seems the more probable

---

CARDIAC MANIFESTATIONS OF POLIOMYELITIS

CARDIOVASCULAR collapse is a serious complication of bulbar poliomyelitis Hildes et al[1] point out that it usually develops within forty-eight hours of the onset of bulbar paralysis High pyrexia and tachycardia are common Most patients have a normal blood-pressure until shock begins, when the pressure may fall precipitously or over a period of some hours On the other hand, there may be transient hypertension before the stage of shock Pulmonary œdema is usually a notable feature, the onset of which commonly precedes death by a few hours Hypertension is not confined to acute collapse, Weinstein and Shelokov[2] noted prolonged elevation of the blood-pressure in 7% of all their patients, most of whom had bulbospinal involvement

Electrocardiographic changes have been recorded in poliomyelitis in from 13 to 77% of patients Fox et al[3] described changes in 32% of 189 cases, they believe that E C G abnormalities are as likely to appear in patients with spinal lesions only as in those with bulbar involvement They found ST depression and/or T-wave changes in 90% of patients with E C G abnormalities—a figure comparable with that of most observers Changes in conduction, whether supraventricular or ventricular were unusual

It was not realised until 1942 that the heart could be directly affected by poliomyelitis, Saphir and Wile[4] then demonstrated lesions in the myocardium in 6 out of 7 fatal cases They found extensive perivascular foci of lymphocytes and polymorphs throughout the myocardium and in the subendocardial tissue Monocytes were sometimes present and there was multiplication of adventitial cells Occasionally inflammatory cells invaded the interstitial tissue diffusely, although degenerative changes in the muscle fibres were always mild These features have since been confirmed by others, and it is now generally recognised that myocarditis does develop in some epidemics of poliomyelitis Weinstein and Shelokov[2] believe that the milder form of myocarditis is due to hypoxia, while the more severe kind may be the result of actual invasion of the heart by the virus, but there is little evidence to support such a distinction

The significance of myocarditis as a cause of clinical signs or of death is hard to assess Hildes et al[1] report the necropsy findings in 20 cases of cardiovascular collapse, in all of which there were medullary lesions varying from mild damage to diffuse involvement with focal destruction Although Baker and his colleagues[5] believed that destruction of the anteromedial reticular substance of the medulla was responsible for the onset of circulatory failure, Hildes et al found that the vasomotor centre was often involved in patients dying of causes other than poliomyelitis The invariable presence of medullary damage and the occasional finding of transient hypertension in both fatal and non fatal cases led them to suggest that severe vasoconstriction, arising as a result of the medullary lesion, leads to cardiovascular failure and pulmonary œdema Since myocarditis was present in only 14 of their 20 patients, they do not think it is likely to be the basis of the condition, although its presence would undoubtedly aggravate it The myocarditis is unaccompanied by suggestive clinical signs, it gives rise to no characteristic E C G abnormalities, and only a few cases with E C G changes are subsequently shown to have cardiac lesions

Our knowledge of these features of poliomyelitis and the assessment of their significance is far from complete Hypertension and cardiovascular collapse are probably due to involvement of the vasomotor centre, and myocarditis is probably incidental and not a basic factor in the clinical picture The E C G changes are non-specific and of the same type as those found in other diseases with systemic overtones they do not indicate the presence of myocarditis

ATHEROSCLEROSIS IN THE LOWER LIMB

THE occluding mass in the lumen of an atherosclerotic artery is part atheroma, part thrombosis, and the thrombosis may develop in several layers until obstruction is finally complete It has been known for some time that the common site for the initial block in the arteries of the leg is Hunter's canal, particularly at its lower end near the opening in adductor magnus Why this should be so is not certain although Lindbom[1] suggests that it is intimal hæmorrhage which precipitates the eventual thrombosis and that this is more likely at places where the artery is tethered and immobile so that angulation or traction strains from joint and muscle movement can "fracture" the intima From the area of primary occlusion a secondary thrombosis spreads proximally, and its extent is determined by the calibre of the branches leaving the artery thus the profunda femoris becomes of great importance and its muscle branches often provide the main collateral supply It usually remains patent and remarkably free from disease Less often the popliteal artery is the site of initial thrombosis, which may spread in either direction to the femoral or tibial arteries

The degree of ischæmia caused by occlusion of a large artery depends on the volume and pressure of the collateral flow When this is efficient, as in many lesions involving only a short segment, the patient may have very few symptoms and the flow through the main artery beyond the block is almost normal Often, however, the blood-supply to the feet is inadequate and the clinical picture of acute ischæmia results There are several possible causes general atherosclerosis may make the collateral vessels stiff and unyielding so that they can no longer enlarge, big collateral arteries—for example the profunda femoris or the geniculate anastomoses—may be involved in the clot, or the smaller vessels distal to the main occlusion may be blocked, thus adding a second and disastrous barrier to the peripheral flow

Arteriography has few complications and it has enabled surgeons to follow the anatomical variations of atherosclerosis with considerable accuracy Much of this important information has been reviewed by Mavor,[2] who found the femoral artery to be the site of occlusion in 104 of his 142 patients with atherosclerosis and calf claudication This precise knowledge of the spread of the disease has more than an academic interest since the success of surgery largely depends on the site and extent of the thrombosis In many of Mavor's patients direct surgery was contra-indicated either by the extent of the arterial lesion or because of the patient's general health There is little point in eliminating claudication in a man who has angina after walking 100 yards Mavor claims, however, that local palliative surgery would have been justified in 59% of his patients There are many direct and indirect procedures available which will increase peripheral blood flow When the small distal vessels below the knee are grossly involved a lumbar sympathectomy improves the skin circulation and nutrition but will not improve exercise tolerance Occlusions in the superficial femoral artery are probably best treated by the by-pass operation[3] which is designed to leave the already established collateral circulation unimpaired Thrombosed large-bore arteries, such as the aorta or iliacs, are best resected and the arterial pathway reconstituted with a synthetic or a homologous artery graft The choice of the great majority, who do so voluntarily, be paid cut price rates?

Another fact, well known to the Ministry, is that only a few whole time specialists in general medicine and geriatrics will average more than 30–40 visits a year, if that The whole time specialist who does 33 a year, for which he receives 4 guineas, is actually in pocket, after paying tax and superannuation, £2 3s at the bottom of the S H M O salary scale and £1 8s at the top of the consultant This works out at the princely sum of from 1s 3d to 10d a visit!

The cost of running a car without adequate mileage allowances and income tax relief is fast becoming prohibitive Purchase tax on small cars is up by £30–40 and cost of insurance, tyres, repairs, and so on has risen or is rising steeply Telephone charges are also up

The specialist who is on call for emergency visits must travel everywhere by car and keep his telephone constantly attended These visits, too, are frequently wanted at inconvenient times, and encroach on the specialist's scant leisure Under the new agreement, he must do a considerable number (or none at all) before he even ceases to be heavily out of pocket on each Few general practitioners will feel like calling him out under these circumstances

So in specialties like pathology, radiology, chest diseases, and psychiatry, where the majority of specialists are whole time, patients will be deprived of a specialist's opinion in their homes, and continue to be needlessly admitted to hospital beds, costing 20 guineas or so a week

It has long been evident (and the agreement just mentioned bears out the point) that the manner in which the negotiations about terms and conditions of service are at present carried on in Whitley B Medical Committee is greatly to the disadvantage of whole time specialists

Firstly, there is only 1 whole time regional specialist against 15 part time and a professor from the teaching hospitals, on the staff side, which allows the management side to play off part time interests against whole time In fact when part time specialists' mileage allowances were raised in 1952 regional boards were empowered to cut those of whole timers

Secondly, the grave defect of the Whitley machinery is that the staff side cannot take any claim, however just, to arbitration without the consent of the management side—a right denied to no other grade of health service employee Although the management side has openly acknowledged the injustice done to whole time specialists, it has consistently refused, during four years of negotiations, to either remedy the injustice or allow their claims to go to arbitration

At present the whole time S H M O is earning the equivalent of the lowest paid group of general practitioners pre war, who (according to the Spens report) could not give of their best to their patients because they were harassed by financial worries

The whole time consultant is now paid at the same rate as specialists in second and third rate municipal hospitals pre-war, and critics of whole time service never weary of telling us what conditions were like in those institutions

Whole time specialists do well over a third of the consultant work in the N H S, and if their status continues to be down graded the standard of their work will deteriorate *pari passu*—no political chicanery can disguise or alter the fact

Even Mr Macleod grudgingly admitted, in reply to questions in the House that whole time specialists are unfairly treated, but added that this was a matter for the appropriate Whitley Council' As that excuse has had its day, is his successor prepared to allow the whole time specialists' claims to go to arbitration? What would he have to fear from such a step, if he believed that these claims were being fairly dealt with at present? Now that the claims of whole time specialists have been endorsed by the Guillebaud Committee (Report para 404 "We are also of opinion that it is undesirable that the financial arrangements relating to the consultant service should be such as to provide financial inducement to a consultant to apply for a part time rather than a whole time appointment") the Minister of Health cannot any show of justice, refuse either to meet them or to al them to go to arbitration

It has been suggested by my colleagues and m that the formation of a whole time specialists g comprising S H M O s and consultants, under the of the B M A, would enable us to press our claims vigorously, and letters in support of this view h poured in from all over the country

LEO GILCHRIST

PULMONARY EMBOLISM AND 5-HYDROXYTRYPTAMINE

SIR,—Your annotation (Feb 4) comments on an experiments showing that the vascular effects of hydroxytryptamine are antagonised by the "a adrenaline" drug, 'Dibenamine' You suggest that t drug might possibly be of therapeutic use, but that still in an experimental stage

This compound was the first member of the β haloalk amines found to have "anti adrenaline" activity, and action has been very thoroughly investigated It antagonis the excitor effects of adrenaline, noradrenaline, and ma other sympathomimetic amines[1] Replacing one benz group by a phenoxyisopropyl group results in a benzyl chlorethylamine hydrochloride, 'Dibenyline' ('Dibenzyl or 688A in America), which is well tolerated and is ora active and has been subjected to more extensive clin investigation It has been found useful in the treatment peripheral vascular disease and allied conditions, and is n available for clinical use

Further clinical investigations have been suggested in various other vascular conditions, in hypertensive stat including eclampsia, in migraine, and in chilblains, in wh some of the following factors are thought to be implicated (1) increased sympathetic activity, (2) increase in circulat pressor substances, (3) increased vascular sensitivity t pressor substances, (4) conditions in which increased bl flow might result from reduction in normal sympathetic to Some of these investigations are being undertaken currently

MESTINON IN CEREBRAL PALSY

SIR,—From time to time it has been claimed th cholinergic substances benefit some cases of cerebral palsy Neostigmine has been used with varying succ it has the disadvantage that it may produce gastro intestinal side effects necessitating the concomitant u of atropine A new compound 'Mestinon' (the dimeth carbamic ester of 1-methyl-3-hydroxy pyridinium bromide) is claimed to be longer acting and to have few visceral side effects than neostigmine I found that in children with cerebral palsy mestinon, given by mouth half an hour before a physiotherapy session, seemed to enhance the value of that treatment for those who main disability was spasticity, and to a lesser extent for those having athetosis with tension Those with ataxia derived no benefit

A controlled trial was then carried out over a peri of three months

It was decided to test the drug only in "spastics," and 32 children were paired as closely as possible on the bas of age, type of disability, and severity Some of the children were in a special residential unit and others attended as outpatients One child of each pair received 20 mg of mestinon twice daily, and the other received an inert tab of identical size The identity of the active tablet was n revealed by the manufacturers until the end of the trial The impressions of the physiotherapist were recorded at each attendance, as were the impressions of the parent of the day cases and the school teachers of the residential gr

Of those receiving mestinon, 9 were considered to ha improved more quickly than they would have without tab

MALARIA AND THE THAMES *

W D L SMITH
M.B St And, D.P.H., D.T.M & H.
REFINERY MEDICAL OFFICER KENT OIL REFINERY LTD, ASSISTANT PORT MEDICAL OFFICER, PORT OF LONDON HEALTH AUTHORITY

THE early history of endemic malaria in this country can be traced in the writings of kings dictators, essayists, doctors and poets The Venerable Bede, in his Ecclesiastical History written in Latin and boldly translated into Anglo Saxon by King Alfred draws attention to a prevalent long-continued fever, which he calls "lencten adl" ("spring ill") The habit of the parasites to lie dormant during the winter and become active in the spring was therefore familiar to the early Anglo Saxons This high spring incidence was, of course, characteristic of benign tertian malaria, the parasite undergoing the pre-erythrocytic cycle in the liver of the affected person during the latent period That the cause was not a large number of fresh infections in the spring can be shown by comparing the monthly figures for malaria in man with the density of infected anopheles The latter reaches a peak in the late autumn many months after the incidence of malaria passes its maximum James (1929)

It is very difficult to estimate the extent of malaria during early times because the term "ague" was applied indiscriminately to many fevers Historians warn us against assuming that the hot agues the new agues, and the epidemic agues of the 17th century necessarily refer to malaria (Creighton 1894) The Oxford English Dictionary pays little heed to this warning, and without reservation interprets Chaucer's ague as malaria Shakespeare uses the word ague both medically and metaphorically, and occasionally mistakenly When Macbeth says of the force encamped before his castle—'here let them lie till famine and ague eat them up'—he undoubtedly referred to that scourge of armies typhus or spotted ague and not malaria Similarly the ague which paralysed Cromwell's army in Ireland was no doubt typhus However, the essayist Butler, in Stuart times, is correct in his reference to malaria When the lady in *Hudibras* rejects the advances of the Puritan knight, telling him that love is fickle, first hot but soon turning cold she says 'Tis but an Ague that's reverst, Whose hot fit takes the patient first" Butler could use this metaphor in full confidence that its point would be appreciated by his readers, so familiar was everyone with the successive stages of an attack of malaria in those days Today a footnote would be necessary to explain its significance to the ordinary English reader

When Sir Walter Raleigh lay in the Tower of London awaiting execution, relapses of malaria troubled him sorely, and just before the grim procession set out for the place of execution he prayed fervently that he might not be seized with an ague fit on the scaffold lest his enemies should say that he had met his death shivering with fear By a strange twist of fate, King James I, who was responsible for Raleigh's execution, died in a fit of ague Sydenham well known for the accuracy of his observations described malaria or intermittent fever as he called it, in epidemic form between 1661 and 1664 This epidemic was probably precipitated by the extraordinarily hot summer weather of 1661, which lasted through the autumn and winter into the new year, and to which Samuel Pepys refers in his Diary

During the 18th century the Lambeth and Westminster marshes were notoriously associated with malaria but not all the malaria which developed in London was contracted there Malaria had long been accepted almost as an occupational disease among the nomadic hop-pickers of Kent, many of whom returned to London at the end of the season Malaria was described by Daniel Defoe when he referred to the London gentry who went shooting in the Essex marshes and often returned with an Essex ague on their backs which they found a heavier load than the fowls they had shot The first person known to have used the word malaria meaning 'bad air' was Horace Walpole While staying in Rome in 1840 he wrote to Thomas Grey in London describing the local disease as "a horrid thing called the mal'aria, which comes to Rome every summer, and kills one"

The last of the extensive epidemics in this country occurred between 1857 and 1859 coinciding with two very hot summers That malaria was common in Westminster may be gathered from the records of patients treated in St Thomas's Hospital between 1850 and 1860 These show that 1 in 20 patients had malaria In Gravesend Hospital at that time 30% of the patients were diagnosed as having malarial fever The Registrar of Strood wrote in 1857 'an unusually hot summer has operated still more to make the marshes and adjacent districts intensely unhealthy Many deaths have been registered from intermittent fever directly or indirectly (McArthur 1951)

Incidence and Distribution in England

The first accurate assessment of the incidence and distribution of malaria in England became available in Whitley's report as medical officer of the Privy Council in 1863. Whitley's list of places where malaria was known to be endemic corresponds closely to that for the ten years ended 1926 (James 1929 and figs 1 and 2) In other words, the areas which were potentially malarious had changed little in seventy years and in terms of mosquito bionomics, only in those parts of England could the transmitting anopheles thrive The Thames estuary, and particularly the north coast of Kent, have probably been the most important focus of endemic malaria for the past century There was a cynical

* Read at the annual meeting and conference of the Association of Sea and Air Port Health Authorities of the British Isles, June 9, 1955

Recently I examined the body of a man, aged 77, who had been treated with stilbœstrol for prostatic cancer The coronary arteries showed minimal atherosclerosis, in the aorta, though still atherosclerotic and calcified, many of the atherosclerotic ulcers were overgrown by a thin layer of endothelium, presumably the first stage towards healing

Dietetic studies have shown that atherosclerosis is associated with excess fat in the diet[4] Prolonged treatment with anticoagulants recanalises thrombosed arteries[5] which become functionally active[6] It may be possible to "pre select" candidates for coronary disease[7], often premonitory signs are noticed[8] These observations suggest that for these patients as well as those with coronary disease a strict fat-free diet, prolonged anti coagulation, and stilbœstrol therapy are worth considera tion not only as treatment but also as a preventive measure in the "pre selected" and in those who have had premonitory symptoms The possible side effects of stilbœstrol must of course be borne in mind

AN UNUSUAL CASE OF SHINGLES

SIR,—Dr Jackson described last year[9] a case illustrating the long time which may elapse between the onset of herpetic pain and of the eruption, and the diagnostic confusion that may arise in the interval In the following case the site of the lesion was unusual, and the neurological features were more prominent than the dermatological

A businessman and churchwarden, aged 61, was seen on a Saturday evening, complaining of a symptom he said he had never had before—constipation—which had lasted for four days From the Tuesday to the Thursday he had passed no urine Despite this he had experienced no pain, but had noticed tightness and distension of the lower abdomen, which had caused him surprisingly little alarm On the Friday, micturition had gradually become re established, but his anxiety remained on account of his failure to defæcate On examination there was a small area of crusted herpetic lesions, measuring 2 in by 2 in, over the sacrum in the *dermatome supplied by segments S2 and S3*

The inference was that an attack of herpes zoster involving the lumbosacral posterior nerve root ganglia had interrupted the sacral reflex arc, resulting in acute retention of urine and constipation due to the unopposed action of the lumbar sympathetic fibres In addition, interruption of the afferent fibres had disturbed the sensory component of the reflex, as in tabes dorsalis, so that the patient had been unaware of the degree of distension of the bladder, and had had no pain Following explanation and reassurance, function returned to normal in the next two days

M KEITH THOMPSON

ERYTHEMA MULTIFORME EXUDATIVUM

SIR,—Erythema multiforme exudativum crops up only a few times in the experience of those working in general medicine The extensive and severe type which involves at once the skin, conjunctivæ, buccal mucosa, genitalia, and urethra is rare even in skin and infectious disease wards In the following case, in which all those sites were affected, there was good reason to believe that the renal parenchyma and the gastric mucosa were also involved

A married woman aged 73 who had been taking no drugs began on Dec 1, 1954 to have back pain malaise, and anorexia The symptoms continued, and on Dec 8 her throat and eyes became painful The mouth gums vulva and inner surfaces of the eyelids were ulcerated and produced a seropur exudate On Dec 10 she was admitted to this hospital u the care of Dr Emyr Jones, after the onset of pain hæmaturia, and what was thought to be a purpuric r in its early stages The epigastrium, right hypochond and right loin were tender There had been no pre abdominal pain The next day the rash was typical o bullous erythema multiforme The frank hæmaturia cea but albumin and many red cells and granular casts per in the urine The abdominal pain was relieved by milk a alkalis, although it was painful to swallow even fluids D comfort was maximal for about four days, before the ra and mucosal lesions began to improve on palliative treatm only The urine became normal, but the abdominal sympto continued longer A barium meal and radiograph on Jan 1955, showed a small gastric ulcer on the lesser curve A intravenous pyelogram on Jan 13 showed good bilate excretion of dye Before discharge the patient had abdominal symptoms *The barium meal was repeated o* July 22, when no ulcer could be seen

HÆMATEMESIS

SIR,—Mr Brandon's article last week is most interest ing, but there are no controls, and no actual evidence that the patients were benefited by the drugs give Would simple washing out of the stomach be equally effective?

Crichton Royal, Dumfries

J G BANCROFT

SIR,—In his article last week, Mr Brandon revive the adrenaline washing of the stomach, previously out lined in Hamilton Bailey's *Emergency Surgery* He i the first, however, to stress the importance of using a adrenaline 'Stypven' mixture as a diagnostic therapeut test

His paper is a milestone in the treatment of hæmatem esis The reason for my saying so is that I know that t method works Only limitation of opportunity, and du and pensionable ears, have prevented me from carryin out an investigation on a larger scale

The duty surgeon faced with hæmatemesis in a fre hly admitted case has to consider whether the blood come from (*a*) chronic gastroduodenal ulcers, (*b*) acute gastric erosions, or (*c*) œsophageal varices Adrenaline 1 200,000 lavage of the stomach will control bleedin from gastric erosions, because the blood is coming fro capillaries To set up a series of five test tubes and empty into them successive half hourly washings i a satisfying and dramatic demonstration of the efficacy of this treatment in cases of capillary hæmorrhage I have not myself used stypven, but I can see no contra indica tion to its use Unlike Mr Brandon, I would empha e that hæmorrhage from a *gastrojejunal anastomosi can* be controlled by this method Its success depends on the size of the bleeding vessel

If successive washings become less and less blood stained, conservative treatment is strongly indicated An operation may do no good The vast number of negative laparotomies for bleeding ulcers could be avoided by the knowledge derived from preliminary adrenaline lavage Equally, persistent bleeding after adrenaline lavage is a definite indication for surgery, *because th* bleeding must be from a sizable vessel This test ma well be more valuable than routine gastroscopy, becau a final and definite decision for or against operation ma be obtained within two to three hours of admission

In addition to this routine test for hæmatemesis I would suggest the regular passage of a balloon into th stomach The mild pressure exerted when it is pulled up against the cardia will help to control œsophageal hæmorrhage, and thus help to differentiate betwee bleeding of gastric and œsophageal origin Many a Miller Abbott tube lying fallow in the drawers of surgical wards could usefully be shortened *to a length of 3 fe* and used to control hæmorrhage, and transmit adrenaline camps who had not served overseas By the end of 1918 50% of the local population of Grain had contracted malaria, and in many of the old wooden houses particularly near the sea, it was common in a family with 5 or 6 children to have 3 or 4 cases of malaria A feature of this epidemic, which confirmed the local and domestic habits of the insect vector, was that in towns where outbreaks occurred patients were often found to be neighbours Many of the infections among children were not diagnosed for many days or even weeks, and this was one of the most important contributory factors in the large number of cases in Kent in 1917 and 1918 Of the 481 confirmed indigenous cases during this period, 82% occurred in Kent (Shute 1949 and table III)

Malaria became compulsorily notifiable under the Public Health, Pneumonia, Malaria, and Dysentery regulations which were introduced in 1919 and amended in 1926

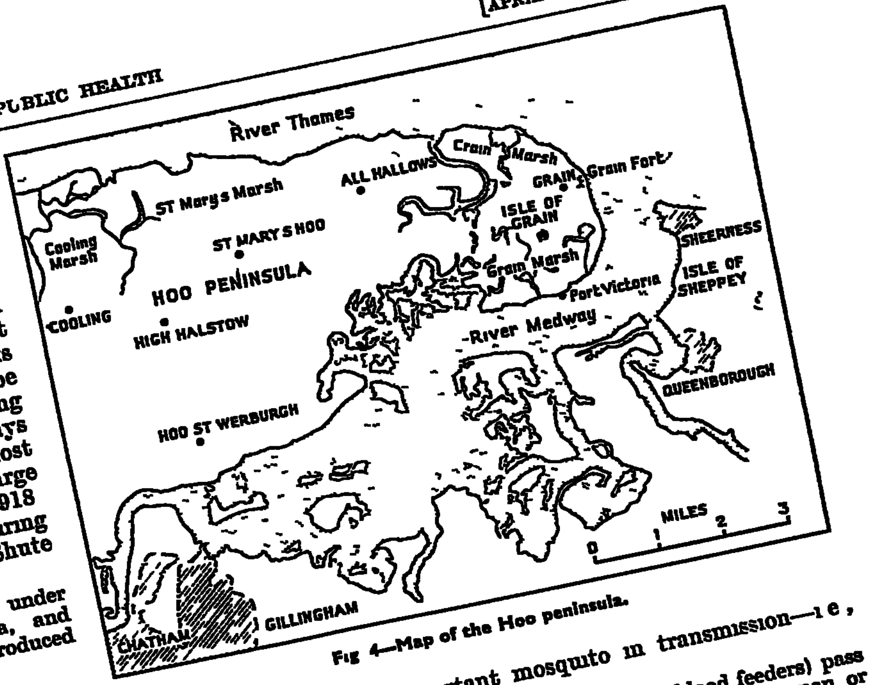

Fig 4—Map of the Hoo peninsula.

The Parasite and the Mosquito

Between the first and second world wars great advances were made in our knowledge of the transmitting anopheline mosquitoes in this country and of the causal parasites, and I will briefly review that knowledge against the background of the Thames

The characteristics of each of the 4 species of parasite show why all the indigenous malaria in this country is due to *Plasmodium vivax*

The tropical strains of *Plasmodium falciparum* are not capable of being transmitted by the English anopheles, and, although the European strain can be transmitted under artificial conditions, the temperature requirements for their development in the mosquito are rarely fulfilled in this country Infections due to *Plasmodium ovale* are comparatively rare, and when they occur they are always self limiting and seldom relapse Although relapses are most persistent in quartan infection caused by *Plasmodium malariæ*, there are few gametocytes in the blood and transmission is infrequent, except when mosquito density is extremely high Lastly, and most important, relapses occur in 50% of cases of benign tertian malaria caused by *Plasmodium vivax* (Shute 1945), and the parasite develops in the mosquito at temperatures as low as 60°F It would appear therefore that only in benign tertian malaria is there a parasite with all the qualities necessary to survive in England

TABLE III—CASES OF INDIGENOUS MALARIA NOTIFIED

County	1917	1918	1919	1920	1921	1944	1945	1946	1947	1948

Sussex		1								

It is possible that in olden days several species of mosquito transmitted malaria, *A plumbeus* breeds largely in holes in tree-trunks or large branches, and may have been a vector when large parts of Kent and Essex were covered with forest There were 2 cases in 1953 of indigenous benign tertian malaria in Lambeth which were thought to have been transmitted by this species of mosquito (Shute 1954) However, in recent years, since the mode of transmission of malaria has been known, there would appear to be only one important mosquito in transmission—i e , *maculipennis atroparvus*

The adult females (which are the only blood feeders) pass the greater part of their lives indoors, either in human or animal houses Once fertilised, the female mosquito remains so for the rest of her life and can begin the next spring's generation of mosquitoes quite independently of the male (Shute 1945) The female requires a blood meal to allow her ovaries to mature (which takes two to six days) and she prefers animal to human blood When her ovaries mature, she leaves the house and lays her eggs in water—preferably brackish water The coastal marshes of the Thames estuary, with their scatter of farms and dwellings are ideal breeding-grounds for the anopheles, and the age old practice in rural Kent and Essex of keeping one or more pigs in dark, warm, poorly ventilated buildings provided ample food and shelter The mosquitoes' preference for animal blood was appreciated by the owners of small holdings, who often used to arrange their pig sties in circles round their houses If there are no animal houses to provide the necessary food and shelter, the mosquito will seek them elsewhere, and a bedroom offers a suitable alternative, especially if overcrowded These feeding habits probably explain the increased incidence of malaria among small children in the Kent epidemic of 1917–19 The female mosquito tends to remain indoors in the late summer, when she has become sexually liberated and has no need to lay eggs, it is then that the danger of several human infections in one house is maximal It is impossible

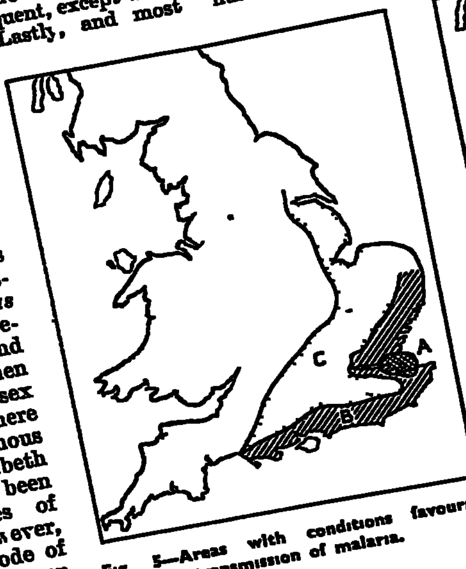

Fig 5—Areas with conditions favouring transmission of malaria.

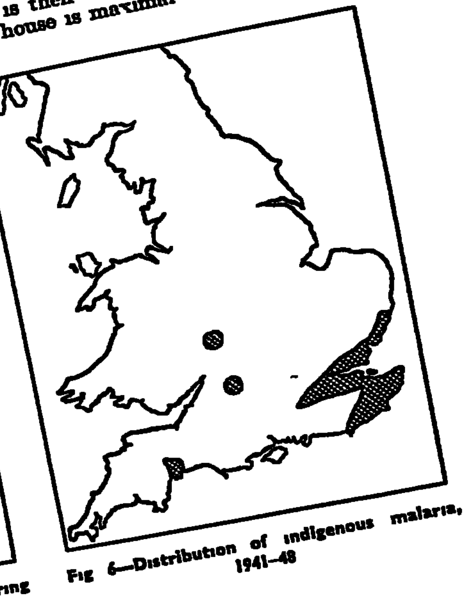

Fig 6—Distribution of indigenous malaria, 1941–48

At first sight the table seems to confirm Dr MacIver's assumption, especially if we consider the first year of life But the difference between the vaccinated and unvaccinated group is not statistically significant, and so we cannot assert that smallpox vaccination protects in any degree against paralytic poliomyelitis We believe that Dr MacIver's observations do not allow any conclusions as long as his material is not statistically proved

These findings are to be published in detail in the *Wiener medizinische Wochenschrift*

CHARLES G SMITH

PLASMA FIBRINOLYTIC ACTIVITY IN CIRRHOSIS OF THE LIVER

SIR,—I would like to congratulate Dr Kwaan and his colleagues on their extremely interesting papers (Jan 21) It seems opportune to mention the results obtained eighteen months ago from an investigation for abnormal fibrinolytic activity in 6 patients with hepatic cirrhosis under the care of Dr Sheila Sherlock at the Postgraduate Medical School of London

Firstly, however, I am a little disappointed to find that Dr Kwaan and his colleagues make no mention of using a low temperature technique between obtaining blood and setting up their tests, especially in the case of their healthy controls

The investigation of spontaneous fibrinolysis has been bedevilled by the lability of the factor responsible, which lability was first reported by us in 1952[2] and was confirmed in 1953[3] *Until then fibrinolytic activity had not been found* in the blood of healthy people at rest, but had been noted only after severe stress[4] Once we had discovered that the fibrinolytic factor is temperature labile in unclotted blood and plasma, we demonstrated considerable fibrinolytic activity in blood taken from healthy people at rest[5] Later we showed that adrenaline and exercise probably only enhance what is normally present[6] In fact, with our method the activity in the resting subject was as great or greater than that found by Macfarlane after adrenaline injection, and our figures with the latter were correspondingly much greater

The relevance of these observations is that if blood or plasma to which an anticoagulant has been added is allowed *to stand at room temperature, its fibrinolytic activity is rather rapidly reduced* The labile fibrinolytic component is stabilised when clotting occurs, presumably by adsorption on the fibrin net work, and can in fact be adsorbed on to pre formed clots from fibrinolytic plasma[7] (This, I would suggest, happened when Dr Kwaan and his colleagues immersed their fibrin webs in fibrinolytic plasma) The fibrinolytic component, according to our observations, is temperature labile whether the blood is obtained from subjects at rest or after stress, or from cirrhotic patients We have, however, some evidence *that when fibrinolytic activity is massive its lability may* be diminished It follows, therefore, that unless the investigator of spontaneous fibrinolysis cools the blood samples immediately and uses a low-temperature technique, or at least makes his clots at a standard *time after* venepuncture, he is in danger of obtaining discordant and confusing results Now that fibrinolysis is giving rise to more general interest the importance of recognising the lability of the fibrinolytic factor in unclotted blood and plasma cannot be too strongly emphasised

This criticism is not intended to cast doubt on the general conclusions reached by Dr Kwaan and his colleagues, since they were dealing with massive fibrinolytic activity, with perhaps a consequent reduction of lability , and if, as one supposes, *their tests* were set up *shortly* after the blood samples were obtained, the results are acceptable , although the criticism does apply to the data obtained with healthy controls *One would, however, be grateful for information* about how quickly the tests were set up

Concerning my own results with cirrhotic patients, the object was to *determine* whether such patients have enough fibrinolytic activity in their blood to jeopardise the stability of blood clots formed in hæmorrhage from œsophageal varices Some of these patients bleed uncontrollably, and if massive fibrinolytic activity were present it might account for recurrent hæmorrhage leading to death A number of investigations were carried out, but only the relevant ones are mentioned here

It was *argued that* if fibrinolysis *in vivo* were responsible for recurring hæmorrhage the most rewarding measurement would be the lysis time of a whole blood clot in vitro We have found, however, that unless a whole blood clot lyses within about twenty four hours of incubation it is unlikely to lyse at all, being adversely affected in vitro by cellular breakdown which is manifested by deep brown discoloration within twenty four to thirty six hours This is not so with whole-plasma clots or buffered-plasma clots[6] The results of the several investigations on 6 patients with cirrhosis are, therefore, given as the lysis times of whole plasma clots with the lysis times of the whole blood clots in parentheses where relevant (the method has been described[6])

Case no	*Sex*	*Lysis times (hours)*
1	F	8½ (11), 55, 5 (6½)
2	F	13 (18), 57
3	F	32, 76, 108
4	F	128 46, 94
5	M	15½ (17), 23 (27)
6	M	3½ (3½) 10 (13½) 97, 77, 10 (14), 92, 13 (18½) 47, 93, 96, 104

Prolonged incubation of citrated plasma, diluted and undiluted, from these patients gave no reduction of fibrinogen content even when fibrinolytic activity was great, which agrees exactly with the results obtained by Dr Kwaan and his colleagues I would question, however, *the authors' statement* about the lack of inhibition obtained with serum plasmin inhibitor They may be correct but they do not make it clear *whether whole serum or a fraction was used* Certainly I found serum itself to be inhibitory

In three experiments in which the patient's serum and my serum were added in increasing amounts to a 1 10 dilution of the patient's fibrinolytic plasma, there was a linear increase in lysis time, my serum being slightly *more* inhibitory than that of any of the 3 patients The results accorded with the observations of Lackner and myself,[8] about the linear relation between dilution and lysis time in our study of normal fibrinolytic activity

None of these patients *had operations* or were given corticotrophin during the period of observation I concluded that on occasion fibrinolytic activity can be sufficient to impair the hæmostatic mechanism, but that it was evidently rather variable in each patient studied As we had been unable to produce significant alteration of fibrinolytic activity with corticotrophin and cortisone in healthy people and in patients with rheumatoid arthritis,[8] the investigation was not carried further

The results obtained with corticotrophin by Dr Kwaan and his colleagues are of the greatest importance and interest It might be rewarding to try the effect of corticotrophin in cirrhotic patients with uncontrollable hæmorrhage, together with observations on fibrinolytic activity and no doubt they have this in mind

Medical Education

REVISION OF THE CURRICULUM

Proposals of the Royal College of Physicians

OVERLOADING of the curriculum is a confession of ucational failure. But so long as medical schools try provide a comprehensive training in all branches of medicine, their curricula will be increasingly overloaded. The Royal College of Physicians believes that the essential first step towards reform is to encourage teaching authorities to study their problem afresh, with liberty to experiment; and it therefore proposes[1] that the detailed *Recommendations* issued from time to time by the General Medical Council should be discontinued, and replaced by a general statement on educational objectives. The college's views on these objectives will be found in the following extracts from a further memorandum, signed by Sir Russell Brain, which it has now sent to the council.

The Aim: a Basic Professional Education

To give, before registration, a full training for any ranch of medicine has become impossible, and to try o do so has become harmful. Instead of a comprehensive vocational training the aim in future should be to give the student a basic professional education of high standard: he should acquire a soundly rooted stock of knowledge on which any branch can be grafted later. It is true that a great many facts must be assimilated by anyone who is going to do any kind of medical work; but, both for the future general practitioner and for the future specialist, factual knowledge is in the long run less important than the ability to learn and go on learning.

On qualification the student will be neither a general practitioner nor a specialist, but should be fit to practise under supervision. His training in science should have given him a scientific outlook, and his training in clinical techniques should have given him skill in collecting information. His methods of thought should enable him to approach any clinical problem rationally, but he should already possess knowledge and experience of the commoner diseases and disorders of function, especially in their early stages, and of the management of emergencies. He should appreciate the doctor's responsibilities to his patient and to the community, and he should be a person of sympathy and understanding.

Premedical Education

Whether a medical curriculum produces graduates with these qualities depends partly on the education the students have received before entering upon their medical studies. The General Medical Council in 1947 described the desideratum here as "a broad general education including the principles of Physical and Biological science," and it would now be reasonable to ask each teaching authority to consider whether or not this kind of education is in fact promoted by the conditions on which students are accepted for medical training.

Insistence on the attainment of a high standard (the "advanced" level of the General Certificate of Education) in three or even four scientific subjects may have the advantage of eliminating candidates who cannot be expected to cope with the scientific side of medical education, and it therefore has some value as a means of selecting students who will later qualify. But it has countervailing disadvantages: first, that the candidate, being induced to amass temporarily a great body of facts, may be led thus early into unsound habits of learning; and secondly that, for most of the future members of the medical profession, a genuinely general education is made to stop at the age of 16 or earlier. Probably few teaching authorities believe that the study of scie from this early age, to the exclusion of other school subje is the proper basis for medical education; yet the effe their regulations is to ensure that the large majority of entrants come to their medical schools with this already specialised education. From 16 these boys and girls have been taught little or nothing but science, and often they have been taught it less for its own sake than as a subject of examination.

In selecting future medical students all teaching authorities, presumably, attach importance to achievements outside science; yet by their own restrictive conditions—for which the General Medical Council are not to blame—they may deprive themselves of liberty to choose candidates whose general attainments they would recognise as outstanding.

A teaching authority, though it may ask for General Certificate of Education passes at "ordinary" level in English, a foreign language, mathematics, chemistry, physics, and zoology (or biology), ought not to insist on passes at "advanced" level in more than three subjects, one of which should be non scientific. Concentration of effort on two scientific subjects, rather than three or four, should leave a boy free for sixth-form work in other disciplines which can help to make him a more cultivated person and eventually a better doctor.

Preclinical Studies

At the age of 18—but no earlier—the student who has been adequately prepared may enter upon his preclinical studies.

The purposes of these studies are to obtain further understanding of scientific method, to strengthen scientific habits of thought, and to learn, in outline, what is known about the structure and function of the normal body and mind. These purposes will be fulfilled chiefly through training in anatomy, physiology, biochemistry, and psychology; but the overwhelming size and continuous expansion of each of these subjects makes it essential that the student's courses in them should be explicitly designed and undertaken as parts of the basic education of a doctor—not as training for a future anatomist, physiologist, biochemist, or psychologist. Furthermore, as part of a continuous process of education, their selective presentation should be closely connected, in the minds of teacher and student alike, with the studies in biology, chemistry, and physics that have gone before, and with the clinical studies that lie ahead.

Generally devoting two years to preclinical studies, some teaching authorities start in the later terms to turn the student's attention from health to disease, with teaching in pharmacology and general pathology, and sometimes with clinical demonstrations. In some medical schools abroad there is, indeed, no formal preclinical period, since the student does some work in the wards from the beginning of his course. Whatever the means adopted, the main object will be achieved if the student is led to look on his academic studies as a useful part of his education for medicine, and if he tries to learn thoroughly in order to equip himself for his later work, not superficially in order to pass the next examination.

The proposal that the preclinical subjects should be taught "in outline" does not imply that they are unimportant. Clearly their importance is fundamental, and every encouragement should be given to some students to study them more fully as subjects for an honours degree. But in actual fact the endeavour to teach them comprehensively to everybody has very often led the student to regard them as something to be committed to memory and then forgotten, and it has tended to obscure their fundamental relationship with clinical medicine. As this relationship cannot be fully appreciated without some knowledge of disease, medical schools will do well to arrange that the teaching of preclinical subjects (especially physiology) shall continue during the clinical period, when it will usually be given to best advantage by members of the

---

[1] See *Lancet*, 1955, ii, 132.

In 1910–47 his colleagues on the staff of the Royal, and the board of management under the chairmanship of Senator Herbert Quin, succeeded in establishing a neurosurgical department for Northern Ireland at the hospital, and appointed Mr Calvert its first director Part of one of the general surgical wards was set aside for the purpose, and operating-theatre and staff provided, and in 1917 the new department began to function In 1953, through the sustained interest of the chairman of the hospital and the approval of the Northern Ireland Hospitals Authority, a new theatre suite and wards were opened, and here in the past three years, at Quin House, he at last saw the realisation of all his hopes and ambitions to establish neurosurgery on a sound footing in Northern Ireland In 1954 he had the great pleasure of acting as host to the Society of British Neurosurgeons on the occasion of their first visit to Belfast He gave then a typically honest and severely critical account of his own personal experiences with a series of cases of spontaneous subarachnoid hæmorrhage which he had treated as surgical emergencies Last summer he went to Canada for the joint meeting between British and Canadian neurologists and neurosurgeons, and spent some time at the Institute of Neurology in Montreal and other centres in the United States In the autumn he had been elected vice-president of the Ulster Medical Society

Simple statement of the chief events in a successful life does not always indicate the sources of a man's claim to greatness As a doctor, in every sense of the word, Cecil Calvert was one of the most outstanding men the Belfast School has produced But he seldom published any of his work although we often urged him to do so Writing did not come easily to him, for he had an exceptionally fine knowledge of neurological literature and was overcritical of the worth of his own observations Shortly before his death he expressed a desire to give up part of his routine work in favour of making a special study of surgical aspects of the Parkinson syndrome and other extrapyramidal states, but he never claimed to have any particular aptitude for research As a clinical neurologist he was the best we had Often ill-defined physical signs which, if not missed, were accepted by others as being atypical though not inimical to the diagnosis suggested, proved as a result of his careful appraisal to be signposts ultimately leading to the true localisation and nature of the underlying lesion Where he differed from most of us, and may possibly even be considered as unique, was in the freshness of outlook he could summon without effort to bear on each new clinical problem, a truly remarkable faculty which had to be seen to be believed and which showed no signs of failing at any period in his lifetime He might weary of the topic under discussion at a committee meeting but he was never bored at the bedside or when taking a patient's history, however laborious and time-consuming this might prove to be To him there were no "interesting" cases to whet his appetite or "purely functional" problems to be dismissed after a perfunctory examination Each new patient, no matter what his symptoms, was treated as a distinct entity and with that measure of kindly consideration and depth of absorption as could only arise from the conviction that the whole purpose of his being was to elucidate the particular problem then holding his attention When he had completed his examination he would spend some time making notes in his distinctive neat script, and then he was ready for the next patient Another characteristic trait was the problem which the question of fees presented to him Before he gave up private practice, if patients offered to pay he accepted a modest fee, or more often put them off by saying it would do some other time, and his procrastination in sending out accounts was, of course, well known

Mr Calvert's elder brother, Dr Edwin G B Calvert, is senior physician to the Royal Northern Hospital, London and he has two sisters, Mrs R R Sayers and Mrs Allen, wife of Prof F M B Allen He married in 1930, his wife, Eileen, being the second daughter of the late Mr and Mrs Henry Healey of The Fort, Lisburn From her he received devoted loyalty and support Many visitors to their lovely home at the Spa, Ballynahinch, and later at Newtownbreda will remember the graciousness and warmth of the hospitality she provided To his intimate friends he often admitted how much he owed to her, and indeed this could easily be discern by all who knew them, each having a deep regard and affection for the qualities of the other

R S A

During the late war, Cecil Calvert was chosen b Sir Hugh Cairns to be officer in charge of the surgical division at the Military Hospital for Head Injur (Oxford), and in this capacity he shouldered the ma burden of brain surgery in that hospital The mos difficult and time-consuming cases were generally p on his operating-list, as everyone knew that he would spare no effort and grudge no time in achieving his h challenging standards, for only the best would satisfy him

Perhaps the worst types of brain wound, from th surgical point of view, were those which shattered th floor of the anterior fossa The debridement of the wound had to be followed by a tedious repair of the torn meninges, and Calvert's success with these difficult cases was unrivalled During the invasion of Europe there were fresh cases admitted in groups nearly every day, and his life during long periods consisted of operating sleeping and eating

Calvert was so modest and unassuming that we often wondered whether he realised the importance of his work, and certainly he would vigorously disclaim any attempt to describe it in terms commensurate with its great worth As a professional colleague and friend no-one could have been easier to work with Clinical problems were discussed with all who could possibly help, advice was carefully listened to, and differing views would be balanced fairly against his own before a final decision was taken A keen sense of humour led to words of kindly banter being exchanged, but there was never any possibility that either personal dignity or prestige of his specialty would be allowed to interfere with the main object of his work, which was to do the best that was humanly possible for the patient

By his tragic and sudden death at the height of his career, British neurosurgery has suffered a grievous loss, and many of us have lost a great friend

W R B

FRANCIS EVELYN JARDINE

M B Edin, F R C S E

As we announced last week Mr Frank Jardine died on March 27 at his home at Elie, Fife, to which he had retired

He was educated at George Heriot's School and at the University of Edinburgh After he graduated in 1908, he held house-appointments at the Royal Infirmary and later became private assistant to Francis Caird, whose surgical disciple he was In 1912 he took the F R C S and in 1919 he was appointed assistant surgeon to the Royal Infirmary He also served on the staffs of the Vert Memorial Hospital, Haddington, the Dumfries and Galloway Royal Infirmary, the Kirkcaldy Hospital, and the Royal Victoria Tuberculosis Trust From 1917 to 1949 he held office as president of the Royal College of Surgeons of Edinburgh, and in 1950 he retired from the staff of the Royal Infirmary

W Q W writes

"Frank Jardine's surgical technique was based on that of Caird, and, though in some respects he was excessively conservative, his methods, on the whole, were sound and successful He was associated with the department of anatom in the University of Edinburgh for many years, first as demonstrator and later as lecturer in applied anatomy, and there is no doubt that his thorough knowledge of anatomy contributed a great deal to his success as a surgeon He was an excellent teacher and his simple direct style and often homely or humorous illustrations made him a great favour with undergraduates He understood hospital patients we and was able quickly to get on easy terms with them hi exchanges, sometimes in the vernacular, were often mos entertaining to his students and were appreciated by th patients Apart from his professional career, he will be lon remembered for his personal qualities He had a gift fo friendship, which included his own teachers his colleagues hi patients, his students, and his nursing staff His hospitality both at Edinburgh and Elie, leaves grateful memories t many He had a great sense of fun and appeared to see onl the brighter side of life his ready wit and quickness a repartee made him excellent company whether in his own home or at social gatherings His recreations were golf and given time and opportunity, the teacher will study the varying needs of individual students so that each may be aided, guided, and inspired to learn for himself

The Council's Responsibility

The duty of the General Medical Council to ensure that, registration, practitioners possess "the requisite nowledge and skill for the efficient practice of their rofession" has hitherto been discharged (1) by recommendations as to the conditions on which teaching authorities should grant registrable qualifications, and (2) by inspection of the qualifying examinations of the licensing bodies Discontinuance of the issue of detailed recommendations (as proposed by the college) is now possible because the General Medical Council's power of inspection has been extended by the Medical Act, 1950, to the medical schools in which the candidates for registration are taught Believing the quality of these schools to be of primary importance, the council may decide to make use of this power of inspecting them, and will thus be in a position to make recommendations specifically to individual schools rather than generally to all

Examinations are potential instruments of education though they should not control its course, and the therefore form an integral part of a curriculum The college suggests that, to encourage teaching authorities to review their curricula fully, the council should issue no general instructions on the content or timing of any examinations, for such instructions would limit the scope of the review and might prevent the development of a method of progressive assessment which could be an alternative to the present examination system Since a curriculum and its examinations need to be considered together, the council's inspection of a medical school's examinations should henceforward be part of their inspection of the medical school itself

In inviting teaching authorities to reconsider the curricula, and licensing bodies to reconsider their examin tions, the council might ask each such authority or bo to submit, within two years, a statement on its pol and on how this policy is to be realised

TOOTHBRUSH HYGIENE IN HOSPITAL

FRANK BROOK
F.D S , H.D D
ASSISTANT DENTAL SURGEON, LEEDS GENERAL INFIRMARY ,
CHAIRMAN OF LEEDS (GROUP B) HOSPITAL MANAGEMENT COMMITTEE

ORAL hygiene is difficult to maintain in patients with severe mental disease In the training of nurses stress is d on the importance of a clean mouth, but in over- owded and understaffed wards there is a wide gulf etween theory and practice

In many hospitals the nurse hands out the toothbrushes immediately before their use, and collects them afterwards For each brush to be inspected and placed in its individual container, ready for the same patient to use next time, takes more time than can normally be given

In some hospitals the brushes are tagged with the names of the patients, but are then placed in an antiseptic solution in a single container , the bristles of different brushes often come into contact with one another, and some antiseptics injure the attachment of the bristles to the head of the brush

THE ANTISEPTIC

Viefhaus[1] in 1932 reported that toothbrushes can be rilised quickly and efficiently with a 1 in 200 solution 'Carvasept,' which is, I am informed,[2] a preparation f monochlorisothymol Viefhaus said that after dipping he brush in the solution enough antiseptic remained on he bristles to make them spore free in ten minutes There were no deleterious effects on the brushes, even when they were immersed in the solution for three weeks, and the bristles remained hard and elastic Furthermore, the odour and flavour of monochlorisothymol were in no way unpleasant, and were, in fact, more pleasant than certain mouthwashes

Preparation —Monochlorisothymol[3] is insoluble in water, but a stable 10% emulsion may be prepared from the following materials[4]

Monochlorisothymol	100 ml	Oleic acid *B P*	2
Castor oil *B P*	50 g	Alcohol 95 % *B P*	1
Potassium hydroxide *B P*	10 5 g	Water sufficient to produce	

Dissolve the potassium hydroxide in 10 ml of d water and mix this with a solution of the castor oil in of the alcohol Allow to stand for one hour, or until portion remains clear when diluted with 19 times its of water

Stir in the oleic acid until a few drops of the solution a bluish green colour with bromothymol blue (*B P*) Dissolve the monochlorisothymol in the remainder of the alcohol and mix it with the above solution Carefully add sufficient water to 1000 ml and mix well

To obtain the 1 in 200 dilution required for sterilising toothbrushes, add a litre of water to 50 ml of this 10% emulsion

Investigations —Bristles from 6 used toothbrushes gave an average bacterial count of 1200 million organisms per bristle After soaking in a 1 in 200 solution of monochlorisothymol for various periods the brushes were washed in sterile saline and the bristles were cultured Organisms were present on brushes soaked for five, fifteen, and thirty minutes, but not on those soaked for one hour or longer[5]

Experiments on mice suggest that monochlorisothymol is not toxic in concentrations likely to be used for sterilising toothbrushes

The conclusion reached was that used toothbrushe should be soaked in a 1 in 200 solution of monochloris thymol for two hours, and washed in water before they are used again

THE STERILISING CABINET AND ITS USE

This is not a new idea

Bartlett[6] described toothbrush cabinets varying in size from those holding 100 brushes to those holding 20 No brush came into contact with its neighbour, and the brushes were renewed monthly, or oftener, as circumstances demanded Each cabinet was equipped with a metal container holding a fresh solution of 10% formalin, which was inaccessible to the patients

The toothbrush cabinet which is in use at Meanwood Park Hospital, Leeds (see figure), is made of stainless steel, the inside measurements being 15 × 12 × 7½ in[7] The lid is perforated so that the brushes may dry, and is divided into two equal parts by a vertical partition The first-class observer and a good bird man He was a constant attender at meetings of the British Ornithologists Club He rarely spoke in the formal discussions and I do not believe that I ever heard him read a paper, but his comments and remarks delivered in his honest-to God manner were always pithy and to the point I remember a heated and apparently interminable argument between two eminent ornithologists upon the exact method employed by the cuckoo in laying its egg and *swallowing* it, as had been claimed The question arose as to what the cuckoo did next During an awkward lull came a typical "snork" which expressed in vivid ward-room phrases his opinion of the question The male members endeavoured to hide their mirth, but the ladies gazed at each other like hen pheasants startled by the bark of a fox

Notes and News

WELLCOME MUSEUM OF ORTHOPÆDICS

At the Institute of Orthopædics [1] on April 4 Sir Henry D opened a new Wellcome museum With what he described as a modest allocation of money, and certainly with a modest allowance of space, the organisers have evidently given a great deal of care, time, and knowledge to the creation of this museum Indeed, Sir Henry implied that if the Wellcome Trustees could rely on the institute's success as a precedent they would hesitate ever to make more generous grants

The era when morbid anatomical specimens were regarded as the fountainhead of all medical teaching has passed it is the intimate structure of the cells and the chemical changes in the blood that now chiefly claim our attention A museum today must therefore do far more than provide space for row upon row of dust collecting pots, and, to be useful to the clinician, a museum of bone and joint pathology requires, in particular, X-ray plates, microscopic slides, and clinical and biochemical data The way in which, in this Wellcome museum, almost complete visual representation has been given *to a number of orthopædic diseases reflects the highest credit* on Dr H A Sissons and his team In the section of metabolic bone diseases especially, they have done remarkably well—by judicious selection and uncrowded display of naked-eye specimens, histological slides, and radiographic plates, with concise, illuminated captions

The present exhibition, entitled Pathology of Bones and Joints, will remain open until April 27

MELLANBY AND THE VITAMINS

At the time of his death Sir Edward Mellanby was chairman of a committee which had been entrusted by the British Council with the task of organising a symposium on Recent Research on Vitamins As a tribute to a great investigator in this field, the current number of the *British Medical Bulletin*, in which the symposium has been published, is arranged as a memorial volume Sir Rudolf Peters has contributed an introduction, and Sir Charles Harington a short appreciation of Mellanby's work and character Dame Harriette Chick and Margaret Hume refer to his many years of service in presiding over the Accessory Food Factors Committee

One of Mellanby's main interests was the study of bone formation, and particularly the influence on bone of vitamins A and D In the symposium Honor B Fell describes investigations, in which she collaborated with Mellanby, on the effect of excess of vitamin A in disorganising the growth of bone in tissue culture W I M Holman and R A McCance review the rôle of several vitamins on bone formation, and they cover Mellanby's early work on vitamin D and on the anti *calcifying action of phytic acid Vitamin* A is the main subject of an article by R A Morton and T W Goodwin, and this vitamin also figures in contributions by H M Sinclair on vitamins and the skin, by Antoinette Pirie on vitamin deficiency and vision, and by M E Coates, S K Kon, and J W G Porter on vitamins in animal nutrition

E Lester Smith describes the structure of vitamin B_{12} as elucidated by Sir Alexander Todd, Dorothy Hodgkin, and their colleagues the locating of the cobalt atom and cyanide group at the centre of an incomplete porphyrin system has been a great triumph both for British chemists and for X ray crystallography L J Witts discusses the levels of B_{12} and other B vitamins in the blood and gastro intestinal tract particularly in relation to pernicious anæmia C E Dalgliesh traces the complex paths by which the amino acid tryptophane can be converted into the vitamin nicotinamide, another vitamin, pyridoxine, takes part in the conversion Adrien Albert reviews the important subject of antivitamins anti metabolites, and chemotherapy Discussing vitamins and the protection of the liver, C H Best, C C Lucas, and Jessie H Ridout refer mainly to the lipotropic action of choline and other substances with labile methyl groups

Outlining our knowledge of the biochemistry of vitamin C, L J Harris points to topics requiring further research, such as the reasons for the somewhat haphazard distribution of vitamin C in animal and plant life L W Mapson deals with the effect of commercial processing on the vitamin content of foods New ground is broken by T Moore in an article on t they were. We now have big chairs and little chairs, have chairs with larger wheels in front and those h smaller wheels behind, some are made of wicker, ne of wood, and some of iron, some take up more om than a bedstead, while others can be folded up and rried about There are a hundred-and-one other efinements—straight backs with round seats, round backs with square seats, and square seats with round holes The matter is clearly one for a specialist, and in due course we had word that the Ministry's Senior Wheelchair Consultant was on his way

---

[1] The Institute of Orthopædics (University of London) 234 Great Portland Street London W 1

Hasty arrangements were made so that everything would be ready on his arrival The patient s bi-weekly bath was antedated, fresh flowers appeared on the bedside locker, and the house-physician brought the notes up to date At last he arrived, armed to the teeth with official-looking documents. Irrelevant items, such as obstetric history and the width of the neighbours' front garden gate were painstakingly recorded, and then he asked to see the patient To our amazement, he confined himself to a detailed dental examination and, carefully noting that 70% of the upper and 100% of the lower teeth were false, he packed his instruments and left

Not only are we sorely perplexed—we are exceedingly worried All this happened six months ago and the patient has since had the left upper canine extracted Will the wheelchair, when it comes, still fit?

* * *

The *Pharmaceutical Pocket Book* stands between the tinctures and the syrups I don't know why. One of my dispensers put it there years ago, and there it stays Not untouched, and not quite unread I glance at it sometimes when the summer evening surgery is slack nd I can smoke a pipe among the bottles Its dictionary f synonyms is always rewarding, with Abernethy's Pill eading like a string of racehorses Basham's Mixture, Black Juice, and Blue Butter The "C's" bring Chinese Blistering Beetle, Clap Mixture, Crab's Eyes, and Cube Root, followed by Fiddle Gum, Guinea Grains, Essence of Smoke, and Everlasting Pills, Poke Root, Polishing Crocus, Surfeit Water, and Tincture of Steel. Asafœtida answers surprisingly to both Food of the Gods and Devil's Dung Aloes is a favourite, for Lady Hesketh —and Lady Webster have pills of aloes and mastic, Chapman s and Gregory's Dinner Pills combine it with ipecacuanha and rhubarb, Marshall Hall's Pills present with liquorice, hardsoap, and treacle, and its compound ecoction—or Apozem—is also known as the Balsam of afe But some might prefer the milder Lenitive Electuary —or confection of senna Atramentum Nigrum (black nk) and Uvæ Passæ Minores (currants) might not get past on an E C 10, but there could be no objection to the King of Denmark's Chest Mixture of extract of liquorice, fennel water, and anisated liquid ammonia But Red Bottle is my favourite, with its suggestion of simple tricolour dispensing However, not all the long list is so satisfying To read, for instance, that Cabotz means kousso and Carrageen chondrus is merely exasperating The book is still between the tinctures and the syrups, and I often wonder when I catch sight of it what chondrus is and whether you drink kousso or rub it in the scalp

* * *

The child mind has an upside down, non-adult, non-victorian attitude to life. If this was more universally recognised the rewrite of existing plots for children's books and plays would perhaps supply work to psychiatric ior registrars in their spare time I took my children t week to see *Beauty and the Beast* done by a good mpany In the car on the way home a post-mortem as carried out as to whom each child liked best The atter was clinched by Elizabeth, age 9 "I preferred," he said, using her present favourite word, 'the Prince when he was a pooser" I can see now that the actors should have been feline and the beast human It's all so obvious

* * *

PRESCRIBERS' NOTES II

Effective against conditions caused by the administration of antibiotics

Thrushes are singing in my patients throats,
I feed them daily crumbs of penicillin.
Ah! where would be those liquid, bubbling notes
If I had had no E C 10 to fill in!

Letters to the Editor

THE ROYAL COLLEGE OF PHYSICIANS

SIR,—The leader entitled The Gold-headed Cane, in the *British Medical Journal* of April 7, received publicity in the lay press and I am therefore asking you, as well as the Editor of the *Journal*, to publish this letter

The leader calls for comment for two reasons It seriously misrepresents the work of the Royal College of Physicians, and it exemplifies a growing threat to freedom in medicine It complains that the policy of the College is faltering, and shows "confusion of purpose" and that it seems "to be a little doubtful about what its responses should be to the Welfare State and its centre-piece the National Health Service" In fact the policy of the College has from the beginning been a firm and consistent one of cooperating with the Government of the day, and taking a share in the decisions on all matters arising out of the Health Service, including remuneration, of which the leader, somewhat inconsistently, goes on to complain Those, however, who have followed the policy of the British Medical Association and views of the *British Medical Journal* on the Health Service will be familiar with their vacillation, and if one wants examples of confusion of purpose one need look no further than the B M A whose leaders recently had to eat their words on the heroin ban, and withdraw their evidence from the Royal Commission on Marriage and Divorce

The leader complains that the College Officers are out of touch with the Fellows and Members It is true that the democratic practice of the College is not identical with that of the B M A, and that its tradition gives the President considerable freedom of action, safeguarded by requiring him and the other College Officers to be re elected annually But every Fellow has a right to attend Comitia, and no Fellow ought to complain that a subject has not been discussed there if he has himself failed to attend and raise it The allusion to Members seems to be based on sheer ignorance, for Members' meetings are held twice a year with the President in the chair, and Members are free to express their views on any subject arranged by their own committee, as well as electing two representatives to the Council

But the leader also misrepresents the College by implying that medical politics is its main interest It entirely neglects to mention the large amount of work done by the College committees which have made substantial contributions to undergraduate and postgraduate medical education, and expressed the views of the College on many clinical, scientific, and sociological topics And the College is even now developing plans for extending its building and expanding these activities

I note in passing that in discussing the limitation of the tenure of office of Presidents of the College and of other institutions the leader does not mention that the Chairman of the Council of the B M A has served in that office since 1949, but such limitation, as the B M A will no doubt agree, is a matter for decision by the bodies concerned

But the main trend of the leader is the clear implication, which finds support elsewhere in the same issue of the *Journal*, that the B M A should occupy a position of exclusive privilege and power in medicine When the B M A organises a conference on medical education, it is the duty of the Colleges to cooperate, even though they may prefer to confine themselves to their own work in this field. When the B M A is negotiating about medical remuneration, it is the duty of the Colleges to keep silent. When the B M A rules that broadcasting and television appearances by doctors should be anonymous, personal opinions and particular circumstances are not to count.

All these instances show that medicine is not free from the danger, already evident in the industrial field, of the

University of St Andrews

On July 3 the honorary degree of LL D will be conferred on Sir James Learmonth, regius professor of clinical surgery in the University of Edinburgh

International College of Surgeons

Sectional meetings of this college will be held at Amsterdam (April 28 and 29) and at Nantes (May 14–16) A Continental clinical cruise will also be held during May Further particulars may be had from Dr J F Brailsford, 20, Highfield Road, Edgbaston Birmingham, 15

Central Midwives Board

Mr Arnold Walker has been re elected as chairman and Prof A A Moncrieff as deputy chairman

London School of Hygiene and Tropical Medicine

Sir James Kilpatrick has been appointed to succeed Prof Bradford Hill, F R S , as dean of the school He will take office on March 1, 1957, when he retires from his present post of director general of the medical services of the Royal Air Force

Queen's Institute of District Nursing

This institute is to hold a meeting at Church House, London, S W 1, on Wednesday, June 6, at 2 30 P M , to discuss the part of the district nurse in the prevention and care of mental ill health Dr Kenneth Soddy and Dr L S Davies will speak Further particulars may be had from the general secretary of the institute, 57, Lower Belgrave Street, S W 1

Research in Leukæmia

The Leukemia Society, Inc , formerly the Robert Roesler de Villiers Foundation, will award grants in aid and fellowships to support research on leukæmia during 1956–57 Further particulars may be had from the Regius Professor of Physic, University Department of Medicine, Tennis Court Road, Cambridge

International Cybernetics Congress

This congress is to be held, under the patronage of the Belgian ministry of education and of UNESCO, at Namur from June 26 to 29 The programme will be divided into the following sections principles and methods of cybernetics, mechanical brains, automation, cybernetics and life Further particulars may be had from the commercial counsellor, Belgian Embassy, 103 Eaton Square, London, S W 1

Reablement of the Blind

The World Council for the Welfare of the Blind and the World Veterans Federation are sponsoring a seminar on this subject which will be held at the Royal National Institute for the Blind, 224, Great Portland Street, London, W 1, on Monday, April 23, at 10 A M Mr Iain Macleod Minister of Labour and National Service, will be the principal speaker

Ophthalmological Society of the United Kingdom

The annual congress of this society will be held at 1, Wimpole Street, London W 1, on Thursday, Friday and Saturday, April 26, 27, and 28 On Thursday at 9 45 A M Sir Stewart Duke Elder, Mr P L Blaxter, Mr S J H Miller and Prof G P Sourdille will be the opening speakers in a discussion on the Early *Diagnosis of Glaucoma* On Friday at 2 P M Mr A I B Goldsmith Dr M Lederman and Dr J A Dudgeon will speak in a symposium on Herpetic Infections of the Outer Eye

The Doctor in the Chair

Alderman G H Goulden, the mayor of Salford who is also deputy chairman of the local executive council protested at a meeting of the city council (*Manchester Guardian* April 5) at the election to the chairmanship of the executive council of a doctor under contract with the National Health Service Alderman G W Davis said that at a meeting of an executive council he found himself surrounded by doctors dentists pharmacists and other professional men At the election of the chairman there had been 6 laymen to 17 professional men Alderman Dr Joseph Shlosberg pointed out that when complaints against professional men were being heard it was customary for an equal number of laymen and professional men to sit under a chairman with a knowledge of law Councillor John Hall described the administration of the health service as topsy turvy with non medical superintendents running hospitals and medical men in places where laymen would be expected

International Society of Surgery

A general meeting of British members of the society w be held at 3 15 P M on Friday, April 20, in the Royal C of Surgeons, Lincoln's Inn Fields, London, W C 2

Institute of British Photographers

Medical Group —A conference will be held by the g at St Bartholomew's Hospital, London, E C 1, on Satu April 21 at 2 P M Tickets can be had from the m secretary of the institute, 49, Gordon Square, W C 1

Family Planning Association

On Tuesday, April 17, at 6 15 P M , this associatio holding a meeting at Caxton Hall London, S W 1, at Mr J Bronowski, PH D , Mr Julian Huxley F R S , a Canon Mervyn Stockwood will answer questions on Pa hood—by Choice or by Chance

Aims of Medical Education

The London region of the British Medical Students Association is holding a symposium on this subject at the Lond Hospital, E 1, on Saturday, April 21 Tickets may be h from the B M S A , B M A House, Tavistock Square Lond W C 1

International Meeting on Electro-encephalograph

The E E G Society are holding an international Europea meeting from May 24 to 26 at the Royal College of Surg of England, Lincoln's Inn Fields, London, W C 2 Th subjects chosen for discussion are instrumentation recording, and processing methods, and drug effects and E E Non members may obtain further particulars from Dr S L Sherwood, National Institute for Medical Research Mill Hi N W 7

Guildford Group Hospital Management Committee has to over 100 local general practitioners a pamphlet describing t services available in the district for old people A summary of t information has been printed on a leaflet which may be gummed into the fly leaf of a pocket diary

The National Association for Mental Health (39, Queen An Street, London W 1) has published a pamphlet by Miss Adri Trainor L R A M , on *Teaching the Mentally Handicapped Chil Speak* (Pp 20 2s) Miss Trainor describes methods for train the silent child the mongol child and the child who can speak

B C G

SIR,—In your leading article (March 3) on the recent edical Research Council B C G trial you state that Many of us will long regret that we did not press for ch a trial sooner ”

In this connection I would draw your attention to some ents which occurred so long ago as 1943, when at a meeting the Tuberculosis Association (now the British Tuberculosis ssociation) it was unanimously agreed, following upon a scussion on B C G by international experts, that the Minister Health be approached with a view to conducting a trial this country Nothing further could be done until the end the war, but shortly after its close a “ Memorandum on C G ” was prepared by Prof W H Tytler for a joint mmittee of the Tuberculosis Association, the Joint Tuber losis Council, and the National Association for the Pre- ention of Tuberculosis, for the consideration of the then inister of Health and the Secretary of State for Scotland 1947 the research committee of the B T A was inaugurated nd immediately set about drawing up a practical scheme for C G trials which was made available to the Ministry of ealth

In the report of the B C G trial, no mention is made of he B T A and the part it has played over a long period f years in initiating such a trial Much of the credit for his forward-looking outlook must go, therefore, to the ld tuberculosis officers and sanatorium medical officers f the pre National Health Service days and to the two ther organisations associated with the memorandum

THE BASE DEGREES BY WHICH WE RISE

SIR,—Peter Davey combines ignorance with facetious- ess in his letter to Barbara published last week May correct a few of the misrepresentations and add the pinions of a younger pathologist upon this vexed ubject ?

The D C P, but not the D.PATH, is awarded by the Uni ersity of London, to internal or external students who pass the examination The internal candidates are students of the Postgraduate Medical School, and since trainee pathologists in this country cannot afford to spend a further academic year undergoing full time instruction, it is natural that most of them are Colonials However, any pathologist who can show evidence of having spent at least one year studying all four branches of clinical pathology can become an external candidate The statement that the examination is too easy for internal students and too hard for external students is a reflection upon the examiners and is not true

Peter Davey has not yet met anyone who has bothered to take the D.PATH If the old grey mare will bring him in this direction I will be pleased to meet him I will tell him that this diploma is awarded by the Conjoint Board in England and that before sitting the examination the candidate must produce evidence of having studied and practised pathology for three years, two of them at a teaching centre

The possession of either of these diplomas indicates that the candidate has reached a certain practical standard in all four branches of clinical pathology In academic departments it is common for a pathologist to specialise in one subject without any background knowledge of general clinical pathology, this is undesirable

My next point concerns the Edinburgh Membership, there is no such thing as an M R C.P (PATH) of Edinburgh All candidates have to pass papers in general medicine and therapeutics and have to satisfy the examiners in clinical medicine In addition a special subject is offered These range from anæsthetics to obstetrics, pathology (in the sense of morbid anatomy and histology), bacteriology, clinical chemistry, and hæmatology are four separate subjects Any one of these, but not all, may be offered by a candidate who must, however, also pass the clinical examination

Neither this examination, nor the M D, nor the PH D, nor the writing of papers offers evidence of general knowledge and technical ability in clinical pathology

A new examination may be desirable, but in the mean time the D PATH should be considered further with a possible view to increasing its standard and value One obvious defect is that the practical examination, held in Queen Square, is rather limited It should be held over a three day period in a hospital laboratory

Peter Davey lays stress on the writing of papers I hope he expects a higher standard of accuracy in these than in his own jottings which occupy more than two pages of your valuable space

Cambridge

H J WOODLIFF

*** In discussing the possible creation of a Faculty of Pathologists by one or more of the Royal Colleges, Dr Peter Davey said “The R C P won't have us” This should be regarded as a prophecy rather than a statement of fact, and for our part we hope it may prove to have been unduly pessimistic —ED L

PROSPECTS FOR LABORATORY TECHNICIANS

SIR,—Your annotation last week expresses clearly ideas which I have been trying to put forward It seems that laboratory technicians would be well advised to hitch their waggon to the Scientific Civil Service and do away with the individual payments against establishment

Group Pathological Laboratory,
Lakin Road, Warwick

A P PRIOR

VISITING IN MENTAL HOSPITALS

SIR,—Your leading article of March 24 favours unrestricted or very frequent visiting of patients in mental hospitals I am very doubtful whether you are right

You say that there are no insurmountable reasons why all hospitals should not allow daily visits But at present there is certainly a shortage of medical and nursing staff, and attending to visitors takes a lot of time Secondly, the mental patient, whether we like it or not, is differently afflicted from a general hospital patient, and he and his family react differently to his illness Though we may change the names of places and persons, it remains clear that nearly all relatives feel uneasy about, or are actually repelled by, the mentally ill they attempt to deny the gravity of the disease or its very presence—probably because they almost always feel guilty, and feel that the illness is a slur on them and the family The patient may feel very much the same Very often the family either try to sever their connections with the patient (especially if he is a chronic patient and of a bothersome or bizarre type) or endeavour, often successfully, to have him discharged against advice These factors become more manifest if frequent visits are made Moreover, psychological disturbance is not restricted to patients but tends to spill over into their families

There should not be any special difficulty in the way of the psychiatrist meeting the family, as you suggest there may be I think that the frequency of visiting should be left entirely to the informal and sympathetic individual judgment, arrived at after consultation with the relatives and the patient My own experience suggests that psychiatrists are, on the whole, much more willing to talk things over with the relatives than are most doctors in other specialties

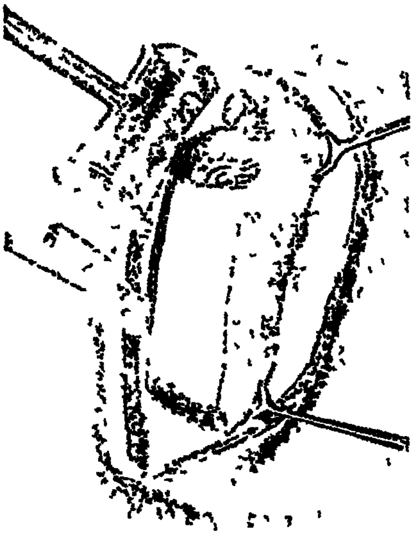

Fig 2—The edge of the sternum is being shaved off with a Lebsche chisel. The dotted line indicates where the costal cartilages will be sectioned.

and some had excision of the sternal head of the pectoralis major. There has been no operative mortality.

The primary tumour in 46 patients has been in the inner hemisphere of the breast, it has been central in 9 and in the upper outer quadrant in 2. Cases have been carefully selected, only inner hemisphere and central growths being treated for the most part. This has been a deliberate policy prompted by Handley and Thackray's biopsy finding that invasion of the internal mammary chain was much commoner when the primary tumour was in the inner hemisphere or central areas of the breast than when it was in the outer hemisphere.

Though age has been no bar, only the fitter of the older patients have been selected for operation; in fact 5 were over the age of 70, the oldest being 75.

Pathological investigation of the specimens removed at operation showed that the state of the lymph nodes was as follows:

Nodes invaded	*No of cases*
None	19 (33%)
Axillary only	15 (27%)
Internal mammary only	11 (19%)
Axillary and internal mammary	12 (21%)

The fact that only a half of the cases have shown axillary metastases is evidence that the series, so far as degree of spread is concerned, is less advanced than most others reported. Nevertheless 23 (40%) of the 57 patients showed invasion of the internal mammary chain, and of these the internal mammary chain alone was invaded in 11 (19%). Tables I and II give a more detailed analysis of the deposits according to site of the primary growth and frequency of invasion of internal mammary nodes in the different spaces.

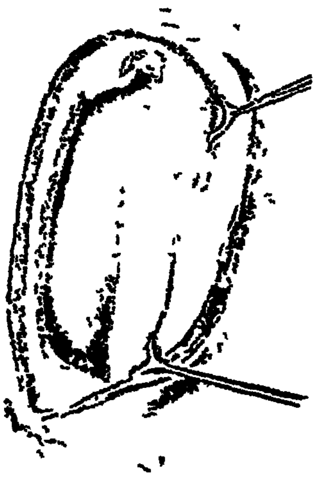

Fig 3—The rectangular area of the chest wall together with the underlying internal mammary vessels and lymph nodes has been removed leaving the pleura intact.

The first 2 patients in the series were operated on in 1952, 8 were operated on in 1953, 30 in 1954, and 17 in 1955. Sufficient time has thus not elapsed to indicate the long-term results. Table III shows the relation between length of follow-up and recurrence or death from carcinoma of the breast. 46 patients are alive without recurrence. Of these 29 had no internal mammary node invasion. The remaining 17 cases have shown invasion of the internal mammary nodes in the following intercostal space distribution:

Spaces invaded	*No of cases*
Upper three	[illegible]
First only	5
Second only	[illegible]
Third only	2
Fourth only	1
First and second	1
Second and fourth	1

Included among these 17 cases is 1 example of lymphatic permeation, 1 of venous invasion, and 1 of invasion of the connective tissues of the upper three spaces. Although no clinical evidence of recurrence has been found seven months, twenty-one months, and ten months respectively, their condition is watched with interest.

Table IV gives details of those 11 patients in whom recurrences have developed and who are either still alive at the time of follow-up or are dead from metastases. No less than 5 showed invasion of the first space internal mammary node out of a total of 13 cases in the whole series in which this node was found to be invaded. It is perhaps this evidence which has led us to consider that the first space should be explored at an early stage of the operation to determine whether invasion is present and, if it is, to abandon the extended operation in favour of a simple mastectomy and radiotherapy. This opinion leans towards that expressed by McDonald et al (1953).

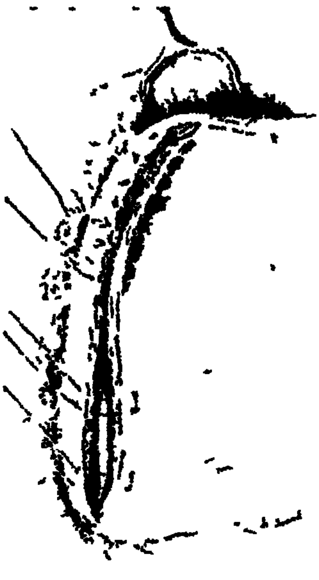

Fig 4—The cut edges of the pectoralis major are sutured over the chest wall defect.

2 patients developed apparent second primary tumours in the opposite breast. Both came in close sequence in the early part of this series and we wondered whether the operation might somehow have provoked the second carcinoma. However both second tumours showed different histological features from their predecessors, and we felt that this quashed all suspicion that the operation might have been responsible.

Of more immediate interest than the recurrence rate, which cannot yet be properly assessed, is the morbidity and immediate postoperative course of these patients. The conclusion may be stated now that there is no

TABLE I—QUADRANT DISTRIBUTION OF PRIMARY TUMOUR AND LYMPH-NODE METASTASES

—	Upper outer	Upper inner	Central	Lower outer	Lower inner	Total
All nodes free		16	1		2	19
Axillary nodes alone	2	8	3		2	15
Int mammary nodes invaded alone		10			1	11
Axillary and int mammary nodes invaded		7	5			12
Total	2	41	9			[illegible]

erican tests are widely used in this country, and when test has not been re standardised, caution is always ded in interpreting the results

The M.M.P.I has not been re standardised, and Cramond's results suggest that the "lie" scale at y rate should not be used in Britain until standardisan data on a British population are available

Woodford Green, Essex JANET CARR

WHOLE-TIME SPECIALISTS

SIR,

"The process of deterioration arising from a sense of ievance on the part of the staff may be a slow one, particuly in a service with the high traditions of the British vil Service, and by the time the tendency manifests itself eparable damage may have been done"—Report of the vil Service Commission

These sentiments apply with equal force to wholeme specialists, most of whom signed contracts in July, 949, after being assured that the then Minister of Health d agreed to accept the recommendations of the onsultant Spens Committee, and that "remuneration as regarded as a subject suitable for arbitration"

The Ministry's refusal to honour its assurances is breach of good faith which cannot be excused by the ibsequent discovery that they were not legally binding his discovery has, however, aroused grave misgivings mongst whole-time specialists about the way in which e negotiations have been conducted since the earliest ays

If, as some still believe, "Spens remains the yardstick f consultant remuneration" then not a single financial ecommendation about whole time service has been fully nplemented The Spens report advised that a wholeme consultant's salary should be from £1500 to £2500 a ear in terms of 1939 values, and that in bringing it p to date due regard should be paid not only to changes the value of money but also to the increased earnings other professions and other branches of medicine

Assuming the specialist is married with two young hildren, we see from the following table (the position efore the 1954 increases is given in parentheses) how the ecommendation has been given effect.

	Gross income today (£)	*Net income after deduction of tax (£)*
Whole time S.H.M.O		
Minimum	1500 (1300)	1251 (1094)
Maximum	1950 (1750)	1553 (1386)
Whole time consultant		
Minimum	2100 (1700)	1636 (1354)
Maximum	3100 (2750)	2091 (1883)
	Equivalent net income in 1938 (£)	*Corresponding gross income in 1938 (£)*
Whole time S.H.M.O		
Minimum	487 (481)	494 (489)
Maximum	605 (610)	638 (640)
Whole time consultant		
Minimum	637 (596)	678 (623)
Maximum	815 (829)	908 (914)

The cost of living has risen by 35% since July, 1949, compared with the 1954 increases of 14% in S.H.M.O salaries and 25–14% in consultant salaries, allowance being made for the Government's contribution to superannuation in all cases The benefit of the 1954 increases has now been wiped out by the subsequent rise in the cost of living, leaving whole-time specialists much worse off today than in 1949

A great deal of nonsense has been talked about the increases bringing whole time consultants' salaries into line with those of general practitioners after the Danckwerts Award in March, 1952 The award of a 100% betterment factor was richly deserved by the general practitioners, who have always conducted their negotiations in a business-like manner Although it did not mean that individual earnings were doubled, it gave the average general practitioner (except the 1000 shortlist men) £3240 a year gross (this figure was given during the debate on the Award and was not denied by the Government) Even though practice expenses amount to over a third of the practitioner's gross income, he scores heavily over the whole-time consultant because he obtains reasonable income-tax relief

The Spens Committee *assumed that* whole-*time* specialists would be paid "any sums which represent expenses reasonably incurred in the course of their work" in addition to the salaries recommended, and these allowances would not be liable to income-tax, and stated

> "The Evidence Committee has brought to our notice a number of items of expense which must be met if the specialist is to perform his duties efficiently These include car expense, expenses of travel apart from the use of a car, the cost of renewal of instruments and other equipment, the cost of books and journals, preparation of scientific papers, and subscriptions to professional societies, printing, stationery and telephone costs, expenses of attendance at national and international professional meetings, and the expenses of visiting hospitals and clinics at home and abroad, and entertaining visiting colleagues"

Few of these expense allowances have been granted none are adequately met

A whole time specialist on call for emergency and domiciliary visits must run a car, yet he is paid for only a fraction of the mileage he covers in the board's service, he is not paid for "routine" journeys to his main hospital even when he must travel by car because he is on call for emergency domiciliary visits or has to undertake other journeys on hospital business Management committees spend limited sums on hospital libraries and so provide some of the books and journals required Although the specialist must have a telephone because of his work, he is paid no portion of the rental, only the cost of outgoing professional calls if he can remember to jot them down In fact many whole time specialists who were formerly employed by local authorities and are now doing the same work under the N H S have had their car and telephone expenses drastically cut Study leave in theory, but not in practice, covers the cost of attending professional meetings Nothing has been done about any of the other expenses

The only expense item in the list on which the whole time specialist is allowed income-tax relief is his £2 a year subscription to a medical defence society

Comparing the terms and conditions of whole time service, we find that the difference in the maximum basic salary of a whole time consultant (£3100) and a part-time doing 9 sessions a week ($9\frac{1}{2}/11$ of £3100 = £2677) is £423, or £185 after deduction of tax

To compensate for his lower salary the part-timer has the following privileges

1 He gets a basic fee of 4 guineas for each of the first 32 domiciliary visits a year (£134), after that both whole-time and part-time specialists are paid at the same rate for the next 168

2 He is paid a travelling allowance of up to £190 a year (which, of course, is free of tax) for routine visits to his main hospital.

3 He is allowed up to 1 hour's travelling time out of each $3\frac{1}{2}$-hour session

4 He is allowed private practice and can thus secure income tax relief on many of his expenses

The fact that the whole-time specialist is, in effect, paid at a lower rate for doing exactly the same work as the part-time, and is denied reasonable expense allowances and income-tax relief, causes bitter resentment The most recent example is the new agreement about domiciliary visits

Up to now, whole time specialists have not been paid for these visits, though the Spens Committee advised that they should be The fact that under the new agreement whole time specialists will not be paid for the first 32 visits a year is degrading to whole-timers and makes the "concession" practically worthless

Only a *few whole-time* specialists are compelled by the terms of their contract to undertake these visits why should

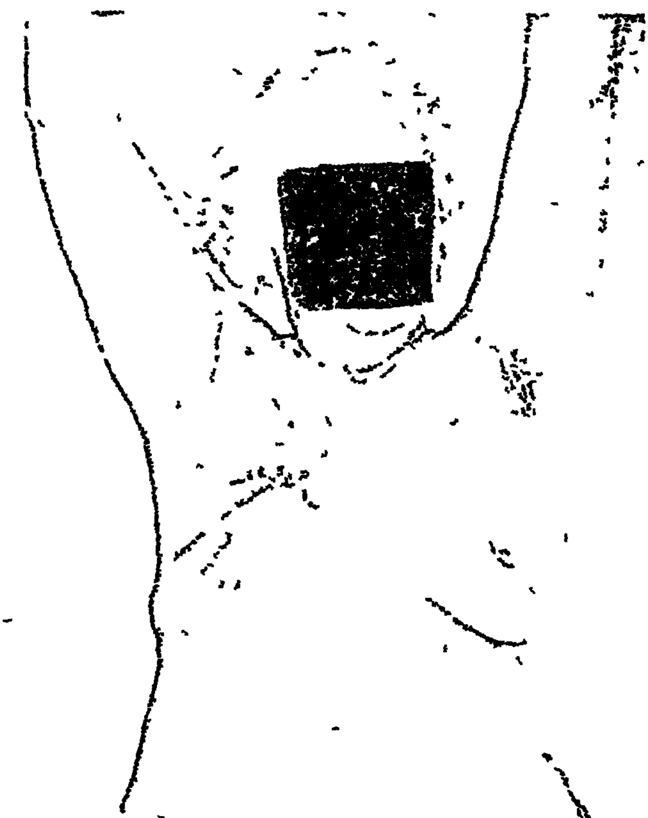

Fig 5—A patient, fourteen days after the operation to show that arm movement may rapidly return to normal

this never occurs Fig 5, showing a patient fourteen days after operation, demonstrates that a full range of movements is possible at an early stage

Œdema of the Arm —This is no commoner than after ordinary radical mastectomy No case of frank brawny arm has occurred Slight swelling of the upper arm has been noted, but is no greater than after standard radical mastectomy

Cosmetic Appearance —There is no significant difference in cosmetic appearance In some earlier cases where the whole sternal head of the pectoralis major was excised, there is some respiratory movement over the excised segment of chest wall In those where the pectoralis major has been left, it is not possible to tell from inspection alone that any of the chest wall is missing and the appearance is much better than after a Halsted operation, because the chest is not hollow below the clavicle

Length of Stay in Hospital —This was twenty four days as an average compared with twenty-one days for the standard operation Hospital beds are thus not much more occupied by this extension of the operation

Discussion

It is necessary first to consider some aspects of the theoretical basis of this operation The preservation of the pectoralis major in a procedure which claims to be radical is a departure from accepted routine The chief reason for ablation of this muscle is to enable the axilla to be easily reached Except in very advanced cases, invasion of the pectoralis major by carcinoma is rare, nor have we seen recurrences in the pectoralis major after its preservation though one of us (D H P) has made preservation a feature of breast carcinoma operations since 1930 The axilla can be reached and adequately cleared if the pectoralis major is preserved by relaxation and retraction The arguments on point are fully stated elsewhere (Patey and Dyson 19 It will suffice to say here that we believe preservat of the pectoralis major is compatible with a truly rad mastectomy

The operation described is not a monobloc proced This may be disadvantageous and is against that princi of cancer surgery which states that a primary tum and its metastases should be removed in one piece. I is no doubt desirable to achieve this if possible, but the present connection the preservation of the pector major (which makes a monobloc operation impossib seems a *very solid practical advantage to weigh agai* a more theoretical disadvantage

The various ways of extending radical surgery f breast tumours beyond its conventional boundaries hav met with some hostility on the score of danger a deformity *Our results show that an extended operati* is not significantly more dangerous, and this is also tru of Urban's technique , and far from being more mutilat than the classical Halsted operation, it is less so becau the pectoralis major is preserved and the chest wall n denuded of its muscular covering

Others have preceded us in devising surgical technique for attacking the internal mammary chain We ow *much to the ideas of Margottini and Bucalossi* (194 Wangensteen (1949), and particularly to Urban (195 who were first in the field They in their turn have pa generous tribute to the stimulus which the patholog investigations at the Middlesex Hospital played i suggesting the need for their operations They have bee followed by Bremer (1953), Sugarbaker (1953), Andreas et al (1954), Redon and Lacour (1954), and Abrao a Gentil (1955) While the technique we have described not so radical as some, we believe that it achieves compromise between doing too much and doing to little

At present two diverging lines of thought are curre in the treatment of breast cancer On the one hand ar those who believe in extending the scope of surgery in th sort of way which has been detailed On the other han *are those who think that surgery should be curtailed an* deep X ray therapy should play the principal role Th latter view has been sponsored chiefly by McWhirte and there can be no question *that his latest re* (McWhirter 1955) at least equal those obtained standard surgical methods X ray therapy will no however, "sterilise" invaded lymph nodes *with a* certainty This has been shown repeatedly *for th* axillary lymph nodes, and one of us (*Handley a Thackray 1954*) has produced biopsy evidence *that ev* after therapy the internal mammary nodes may cont histologically normal carcinoma cells There is th good reason for testing what more radical surgery achieve, because theoretically it may yield better resul Only if it were shown that blood spread is a consta early feature in the dissemination of breast carcinom or that there were other primary paths of lympha spread—e g , directly to the intercostal spaces in t region of the lateral perforating arteries—would theoretical reason for extending surgery be vitiated

There remains the difficulty of nomenclature operations which include excision of the internal ma mary chain *The term "extended radical mastectomy* has been used to distinguish these procedures from Halsted operation This term, coming at a time wh there is a widespread feeling that the extirpative surg of breast cancer has gone as far as is wise, is unfortun because the word "extended" carries an atmosphere the unjustifiable In fact the Halsted operation is re a semiradical mastectomy Pathologically the sort operation which we have described is merely remedyin deficiencies of technique in the old standard procedu those in the control group 4 were thought to have proved similarly

These results are not statistically significant, but some the children who received mestinon continue to prove and have been noticed to relapse if the drug is thdrawn It would seem that further trials are certainly stified

A supply of 'Mestinon' was kindly provided by Roche oducts Ltd

DOCTORS IN COMMERCE

SIR,—One wonders how many of your readers will have oticed an advertisement of a well known drug house on 44 in your issue of April 7, which announces several icancies for "medical representatives," and invites pplications from pharmaceutical chemists and qualified hysicians

I consider—and I believe many of my colleagues will e with me—that a medical qualification should not in us country be used in this connection I am aware iat on the Continent widespread medical unemployment as driven many young physicians into the arms of the rug houses, and I have myself witnessed the unedifying pectacle of a young physician going cap in hand to sell roducts of his particular firm This has not happened ere as yet, but the above mentioned advertisement hould give our elders food for thought as to the increasing conomic straits of our young graduates

It is quite a different matter for a medical man to ork for an ethical drug house in a purely advisory apacity, or in a scientific field such as pharmacology ndeed a healthy critical and objectively creative influence ay be exerted by conscientious physicians in such posts

As a practical measure to put a stop to the attempt o use medical graduates as commercial travellers, I ould suggest that our medical journals take the lead in ot allowing any further such advertisements, and also hat as many members of our profession as possible be oused to show our displeasure at such practices to any ther pharmaceutical companies which may be contemplating such a move

As a medical graduate working myself in a scientific apacity for a pharmaceutical company, I beg you to llow me to sign myself

SCIENTIST

*** We agree with our correspondent, and regret that, y an oversight, we did not represent this view to the irm which sent us the advertisement —ED L

ECZEMA VACCINATUM

SIR,—In regard to Dr Napier's comment (Jan 14) on our failure to find any published reports of strict localisation of vaccinial lesions on the eczematous patches[1] I would like to say that we missed the report by Sommerville et al[2]

This was not listed in the *Quarterly Cumulative Index Medicus* under eczema vaccinatum, eczema or vaccinia—probably because these workers used the term Kaposi s varicelliform eruption, which has been abandoned by many and is used as a synonym for eczema herpeticum by many others

In none of the ten cases described by Sommerville et al was strict localisation of vaccinial lesions to the eczematous patches mentioned Dr Napier s comment about the frequency of this localisation is, thus, surprising Since in eczema vaccinatum (as well as in eczema herpeticum) the eczema determines the generalisation of vaccinia as well as the localisation of most vaccinial lesions, it is reasonable to expect that when vaccinial lesions are strictly confined to the eczematous patches (as in our case) this important characteristic should be emphasised, because of its bearing on the pathogenesis of the vaccinial eruption After all, the localisation of vaccinial lesions on the eczematous patches is not a mere coincidence

Regarding Dr Napier's thesis of direct inoculation of vaccinia virus in the eczematous lesions, this hypothesis is the older of the two concerning the pathogenesis of vaccinial skin lesions , it is also the more obvious and may seem the likelier But most, if not all of those who have tested this hypothesis do not favour it but that of hæmatogenous spread While the existence of lesions on the inoculation site is generally admitted, these lesions rarely appear in man (except after inoculation against smallpox)

As to the significance of the enlarged lymph glands, I again disagree with Dr Napier From our words "a hard painful lymph gland" he deduces that "surely this indicated infection travelling inwards and not outwards" We mentioned that the first lymph gland to appear did so "on the first day of the present illness" simultaneously with sore throat, fever anorexia restlessness, and "the eczematous patches became swollen hot and painful" From these data it is obvious that at least another lymphoid tissue organ—the tonsils—reacted at the same time as the right crural lymph gland This and other clear indications of a systemic reaction contradict Dr Napier's contention that "surely this indicated infection travelling inwards and not outwards" Besides, the enlargement of a lymph gland in the left crural region developed two days after the systemic symptoms and signs

LUIS F DE SALLES-GOMES

CORONARY-ARTERY DISEASE

SIR,—In the past decade observations in the post mortem room and in the laboratory as well as dietetic studies in the field have suggested lines of thought on the pathogenesis of atherosclerosis which may have practical bearing on the treatment and prognosis of ischæmic heart-disease This term is used to include coronary occlusion and thrombosis, myocardial infarction, and fibrosis leading to coronary insufficiency All these conditions are dependent on atherosclerosis

It is not possible by direct evidence to prove that atherosclerosis (formerly atheroma) is a reversible process . at first thought it seems impossible that thickened, diseased, narrowed, and possibly occluded arteries could revert to relative normality or that the atherosclerotic brittle aorta of the old man might change There is, however, some inferential and circumstantial evidence that such changes can take place

For some years I have carefully examined the coronary arteries while doing routine necropsies After a time it became apparent that without any deliberate forethought I expected to find atherosclerotic coronary arteries when examining the body of a well-nourished male over 50 , my guess often proved correct When examining a thin or wasted subject of the same age-group I expected to find relatively healthy coronary arteries , more often than not this presumption was correct

Wilens[1] showed that at necropsy severe atherosclerosis is twice as common in obese as in undernourished subjects 35 years of age or older A high proportion of those found to be undernourished at necropsy had been well nourished or even obese before the onset of the terminal wasting disease It would seem that during a period of severe weight loss significant resorption of pre existing atherosclerotic deposits occurs

In doing routine necropsies I noticed the relative absence of atherosclerosis in the coronary arteries and aortas of subjects that had been treated with stilbœstrol for prostatic carcinoma, compared with other male subjects of the same age group[2] Not only was the atherosclerosis relatively decreased but surprisingly the aortas of the stilbœstrol-treated group seemed to have regained the elasticity of youth Rivin et al[3] confirm these findings except for the aortic changes

Untreated epidermal cell
Effect of exposing epidermal cell to anti A (>—<) and subsequently washing
Addition of group A red cells and centrifugation
Human epidermal cell with A antigen on cell membrane
Mixed agglutination
Human epidermal cell without A antigen on cell membrane
No mixed agglutination

Fig 1—Mixed erythrocyte epidermal cell agglutination reaction for detection of the A (and B) antigen on epidermal cells of human skin

surgery The tissue, spread on tulle gras and folded in gauze wrung out in saline solution, was still suitable after storage for one or two weeks at 4°C

Suspensions of isolated epidermal cells were prepared from the stored split skin according to the method described by Medawar (1948) by a tryptic digestion process In brief, digestion separates the skin into two layers, allowing the dermis to be peeled off, leaving a flat sheet of pure epidermis This epidermal layer is rendered into a suspension by scraping the loosened cells into Tyrode's solution Cell clusters are broken up into a fine suspension by repeated drawing in and out of a fine bore pipett The cells are then wash twice in Tyrode's solution

Suspensions of Human Grou A, Group-B, and Group O R Cells

A few drops of blood were obtained by ear-prick and collected into 0 6% tri-sodiu citrate in saline solution Afte two washes in saline solution they were resuspended in a 1 in 100 dilution of inactivated normal rabbit serum previously absorbed free from antibodies for human red cell (hereafter called N R S dilu ent) The purpose of the 1 in 100 dilution of rabbit serum was to prevent the red cells from sticking to the glass slides and coverslips when the test is read

Glassware

Siliconed glassware was used in the tests

Anti A and Anti-B Grouping Sera

These were human sera issued by the National Blood Transfusion Service for routine blood typing

Experimental Study

Demonstration of A and B Antigens on Epidermal Cells

Five drops of a suspension of the human epidermal cells under study were placed in each of two tubes (8 × 50 mm) Five drops of heat inactivated human anti A grouping serum were added to one tube and anti-B to the other tube The mixtures were

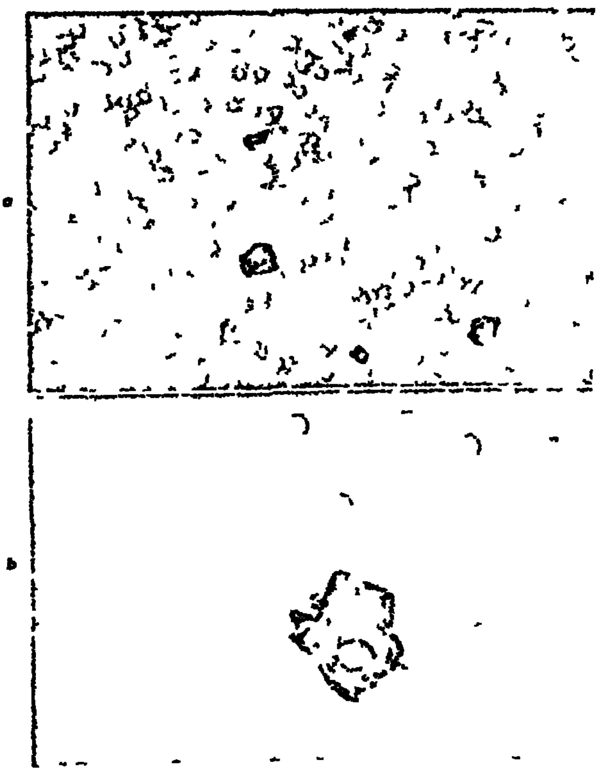

Fig 2—Mixed erythrocyte-epidermal cell agglutination reaction negative result—red cells have no affinity for the serum treated epidermal cells (Phase-contrast microscopy a × 125, b × 500)

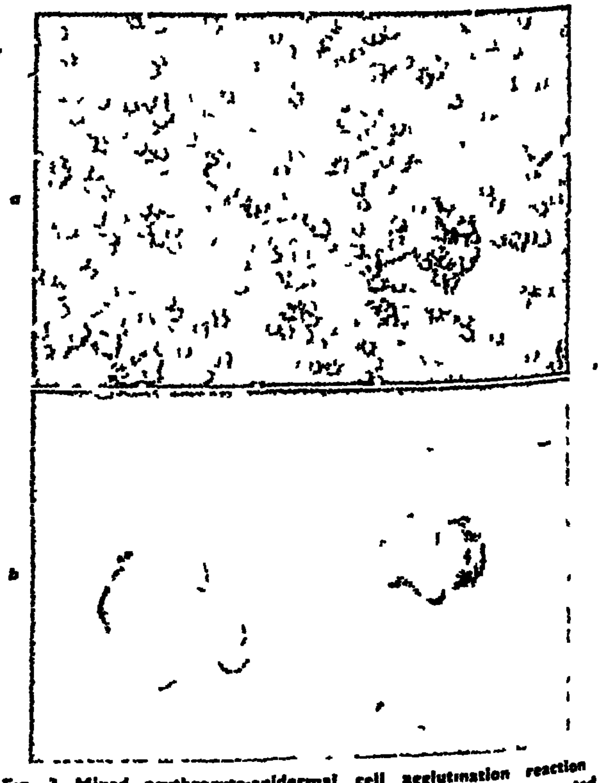

Fig 3—Mixed erythrocyte-epidermal cell agglutination reaction positive result—red cells adhering specifically to the serum treated epidermal cells (Phase-contrast microscopy a, × 125 b, × 500)

Balloon and tube systems of smaller diameter will make the swallowing more popular

Though I have encountered no harm from lavage with 1 200,000 adrenaline, wider experience is necessary to ensure that no harm will be done in any particular case

London, S W 10 F E WEALE

DEFICIENCY OF ESSENTIAL FATTY ACIDS

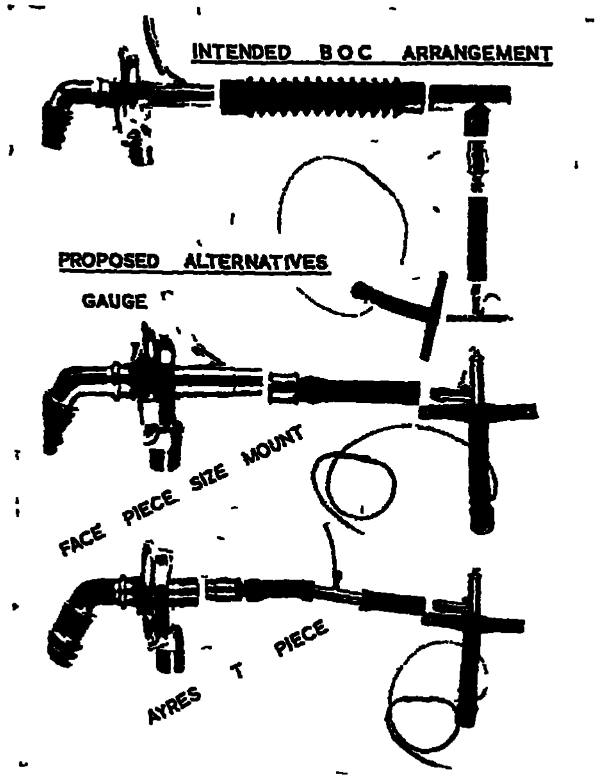
SIR,—With reference to Dr Sinclair's stimulating letter last week, I should like to add that when essential fatty acids are applied to mammalian epidermis there is immediate absorption

The results in cases of psoriasis and acne, after treatment in wet high thermal conditions combined with application of fatty acids, are very encouraging The fatty acids used are the essential fatty acids combined with the saturated and unsaturated fatty acids of the acetic, acrylic, and scorbic series The difficulty has been to prepare these substances without their pungent odours Lanolin and fats, as vehicles for medicaments, must give way to fatty acids on account of the extremely good penetration values of the latter

Tunbridge Wells E F ST JOHN LYBURN

BEAVER MARK II RESPIRATOR

SIR,—It seems that there is some doubt among the recipients of Beaver Mark II respirators as to how these should be connected to tracheotomised patients I apologise that through my negligence this is not illustrated either in the B O C catalogue or in the instructions circulated via the Ministry of Health I hope that the accompanying figure (by courtesy of the Institute of Neurology at the National Hospital) will clarify the arrangement Personally I prefer the "alternative" fittings for reasons of simplicity, and elimination of dead space and potential water trap The figure also shows the moulded rubber, cuffed tracheotomy tubes that have proved completely satisfactory



National Hospital
Queen Square
London W C 1

ROBERT BEAVER

IN THE MENTAL HOSPITAL

SIR,—Your valuable series has given stimulating accounts of ideas and findings in the special field of the "forgotten patient" Perhaps I may be permitted to draw attention to an experiment which might develop into a profitable example of how care, occupation, and daily routine can be combined in order to serve the mentally handicapped

The Camphill Village Trust has been conducting this experiment since September, 1955, on a recently acquired estate in the Cleveland Hills in Yorkshire The Trust was founded by a group consisting of parents of handicapped children and staff of the Camphill and Sheiling Schools (residential schools for handicapped children) Enough funds were raised to secure a start, and the first 25 "villagers" (16 men and 9 women ranging in age from 18 to 38) are now living and working together under the leadership of the Reverend Peter Roth

The aims of the village community are threefold

1 That in a few years, after the initial difficulties of finance and building are overcome, the village be established as a self supporting community, similar to the Papworth Settlement At the moment there are three farms which are already working and run entirely by the villagers, a start has been made towards a weaving shop, and pottery, joinery, and bookbinding departments will be added in time

2 That for none of the villagers fees are to be paid Parents and relatives are invited to make some financial contribution to the Trust if they are able and willing to do so The Trust is to run the village by voluntary contributions until it becomes self supporting Thus everyone in need of this kind of environment will have the possibility of obtaining it Furthermore the villagers know that it is their effort that provides their livelihood Under this arrangement it is hoped to establish in each one of them a fundamental self assurance and dignity, the conviction that it is "their" village which they build and promote will be a great stimulating force

3 That the villagers live together in a small unit of four or five with their foster-parents, who not only look after them but share their life and work No rigid distinction between "staff" and "inmates" is made, social activities are common, lectures and classes are attended by everyone

It is much too early to speak of results, but most of the villagers have settled down very happily, and already show much enthusiasm for their duties and a sense of responsibility which previously had been lacking

KARL KONIG

VACCINIA VERSUS POLIOMYELITIS

SIR,—Dr MacIver (Feb 4) reports an investigation suggesting that the paralytic form of poliomyelitis seldom attacks children who have been vaccinated against smallpox in the previous few years We have taken up his suggestion that larger material be studied and have examined the vaccination state of 111 children in Vienna, under 4 years of age, who contracted paralytic poliomyelitis in the years 1951–55, comparing the relationship between the vaccinated and unvaccinated children in this group with the relationship between the vaccinated and unvaccinated coeval children in the whole population of Vienna The results of this investigation are shown in the accompanying table

VACCINATION STATE OF ALL CHILDREN AND OF CHILDREN WITH PARALYTIC POLIOMYELITIS IN VIENNA, 1951–55

Age (yr)	All children		Children with paralytic poliomyelitis	
	Vaccinated	Unvaccinated	Vaccinated	Unvaccinated
1	14 445	45,269	2	15
2	43 660	18 155	20	11
3	50 776	18 023	20	10

FACTOR IN ARACHIS OIL DEPRESSING SENSITIVITY TO TUBERCULIN IN B C G-INFECTED GUINEAPIGS

D A LONG
M D Lond

A J P MARTIN
M A, Ph D Camb, F R S

MEMBERS OF SCIENTIFIC STAFF, NATIONAL INSTITUTE FOR MEDICAL RESEARCH, MILL HILL, LONDON

ROUTINE testing, by the method of Long and Miles (1950), of an antirheumatic preparation for which cortisone-like activity was claimed showed that it slightly but significantly depressed the sensitivity of B C G-infected guineapigs to tuberculin, but the antiallergic activity was found to be in the arachis oil in which the drug was suspended and not in the drug itself

Fractionation of the arachis oil produced material which, in doses of 6×10^{-8} g per kg of body-weight, maximally reduced sensitivity to tuberculin in sensitised guineapigs The maximal reduction that can be achieved is slightly greater than that possible with cortisone acetate, which requires a dose of 5 mg per kg of body-weight

The antiallergic factor in arachis oil appears to be combined in several different phospholipids with differing solubilities The activity persists after alkaline hydrolysis of the phospholipids, and the active substance appears to be an amine with about 10-14 carbon atoms in it

Coburn and Moore (1943) showed that feeding dried egg-yolk to underprivileged children prevented the recurrence of rheumatic fever in spite of repeated attacks of hæmolytic streptococcal infection Wallis (1954) found that the consumption of eggs was significantly less in children who developed rheumatic fever than in a comparable group who did not Coburn et al (1954) have separated from egg-yolk a phospholipid fraction which possesses antianaphylactic activity in guineapigs and to which the antirheumatic properties of eggs may be due Following Coburn's lead we have found that egg-oil possesses antiallergic activity in the Long and Miles (1950) test and that the active substance appears, in its chemical and biological properties, to be similar to, if not identical with, the substance in arachis oil It thus seems probable that the antianaphylactic substance of Coburn is similar to, or the same as, the antiallergic substance in arachis oil

The antirheumatic property of egg-yolk may be due to its content of biologically valuable protein (Long 1954a) or to the antiallergic factor The protein itself does not possess antiallergic activity

Methods

The biological test is made by measuring the diameter of the lesion produced by injecting two different doses (32 and 320 I U) of Old Tuberculin intracutaneously into guineapigs infected at least a month previously with B C G The active substances were injected subcutaneously dissolved in 1 ml of biologically inactive oil or in aqueous emulsion (Merck & Co, Aqueous Vehicle No 1") (similar results being obtained by either method) five or six hours *before the injection of Old* Tuberculin The diameters of the lesions were read next day Administration by mouth twenty four hours before the tuberculin test also depressed sensitivity, hence similar substances in the diet would presumably be assimilated in man

To detect with certainty a tenfold difference of activity it was necessary to use ten guineapigs in a group In any one experiment eighty guineapigs were used affording seven tests of substance or dose level and one control The guineapigs were used once only

The fractionation methods had to be carefully sele in view of the impossibility of obtaining an accurate of the potency of any substance A method was only value if a clear-cut division into "active" and "inactive" fractions was obtained Usually no procedure w adopted unless the fraction to be discarded proved to b "inactive" at ten times the dose that the fracti retained was "active"

In two successive winters work had to be suspende because the biological tests gave inconsistent resul The variation within the groups increased greatly a later a syndrome developed analogous to kwashiorkor i man This disease occurred in winter in many labora tories (*cf* Paget 1954) in which, as in our case, Bruce and *Parkes* (1947) pelleted diet 18 was the main source of food The addition of skimmed milk to the diet both cured and prevented the disease Skimmed milk was therefore substituted for 5% of the grass meal of diet 18 This modified diet, 18A, which is available commercially from Associated London Flour Millers, enabled us to make satisfactory assays irrespective of season Diet 18A was supplemented, as was diet 18 in previous wo (Long and Miles 1950), by unlimited hay and cabbag

Chemical Methods

A preliminary experiment showed that shaking arach oil (active at about 1 ml) three times with an equ volume each time of methanol extracted the whole the activity (The residue was used as a vehicle f administering active fractions) The combined extra were about twenty times as active as the original o and probably almost the whole of the activity was the first extract When the extract had stood for som weeks, a bulky precipitate was formed which could b centrifuged down and contained most of the activit Extracting this precipitate, which was about a quart of the whole, with 40°-60° b p petroleum ether an later, with acetone left a very small amount of extremel insoluble material, active in single doses of 1 mg p guineapig, which was typical of a phospholipid in it solubility behaviour and physical properties By far th greater part of the activity was left in the soluble part though the activity per unit weight was much le Th suggests that the active substance could be combined in range of phospholipids of differing solubilities

Arachis oil was obviously not the best source of th phospholipid, and it was confirmed that more activ extracts could be obtained from ground-nuts and und from hexane extracted ground-nuts, by extraction wi methanol However, a more convenient source wa "vegetable lecithin" from ground-nuts, which is com mercially available as a by product of the manufacture arachis oil and is active at 1-10 mg

The activity persisted after hydrolysis with alcohol potash, and was found in the non saponifiable fractio There was no evidence of loss of activity, but a su stantial loss could have occurred unnoticed Lar amounts of sterols were crystallised from the no saponifiable matter and were without activity T remaining material, a deep brown oil, became semi sol on standing overnight Molecular distillation at 100 removed all the activity The distillate, which appear to have the whole of the original activity, was a pa yellow oil A small amount of more volatile mater collected in the cold trap and had an activity about tenth of that of the main distillate, suggesting th *distillation at a lower temperature would have be* profitable

By titration with perchloric acid in glacial acetic ac with methyl violet as the indicator, it was found that these fractions contained small amounts of amines T active distillate was therefore distributed betwe acidified 80% methanol water and cyclohexane T activity was confined to the acidified solution In

Obituary

CECIL ARMSTRONG CALVERT

M.B Belf., F.R.C.S.I

Mr. Calvert director of neurosurgery at the Royal Victoria Hospital, Belfast, was killed in a motor accident on April 4, when on his way to the funeral of the late Mr A. H. M Eaton of Omagh The car in which he was travelling collided with another vehicle and his companions Prof F. M. B Allen and Dr. Ivan McCaw, were seriously injured

At his funeral service last Saturday, St Anne's Cathedral was filled to overflowing, and the streets outside were lined with people. This was because he was a man of outstanding quality, and the following accounts of him, by two friends show why he was so much respected and so much liked

* * *

[Green, Belfast

Cecil Calvert was approaching sixty-two at the time of his death although he looked younger and still had more than ample vigour for the exacting nature of his work. He himself however, was not convinced of this; for recently, one evening about 10 o'clock he begged to be excused because he was feeling unaccountably tired. That day had been begun by operating from 2–9 A.M. on a patient with severe head injuries Having completed this task he had gone home for breakfast and a bath returning at 11 to operate on another patient, this time with a ruptured intracranial aneurysm He had successfully exposed and secured this by wrapping it with muscle and the patient had been safely returned to bed by 6 P.M., after which he had just had time for a hasty meal before proceeding to a meeting of the Surgical Journal Club, at which the above incident occurred

He was the second of the three sons of the late Mr and Mrs. James Calvert of Lurgan, his mother being an Armstrong of Tullyweel, Fivemiletown, co Fermanagh Educated at Lurgan College, his first serious interest was in astronomy, and it was with the idea of providing a livelihood, whilst he pursued further studies in this field that he decided first to enter the banking profession Both of his brothers had elected to do medicine, a course to which he was not attracted until later, in 1916 in which year his younger brother Howard, then serving in the Army was killed in action Entering the Queen's University of Belfast in 1917, he had a distinguished undergraduate career and qualified in 1922 obtaining first-class honours and an exhibition in the final examinations After spending a year as resident in the Royal Victoria Hospital he applied himself to postgraduate study in surgery and was admitted to the fellowship of the Royal College of Surgeons of Ireland in 1926 Meanwhile his potential qualities had been recognised and he was appointed surgical registrar and tutor successively Afterwards he worked for some years as clinical assistant to S T Irwin and with R J. McConnell two members of the visiting surgical staff of the Royal for whom he had particular regard, and for whose help in his early days he was always ready to acknowledge his indebtedness

It was about the same time that he met Geoffrey Jefferson through whom I believe he was probably inspired to interest himself especially in the surgery of the nervous system. This interest was fostered by his election to membership of the Society of British Neurosurgeons in 1926 Thereafter, he was rarely absent from meetings of the society, and with other members travelled widely in Europe, missing no opportunity of learning about new techniques and advances in this special field.

At home he had been appointed to the Ulster Hospital for Children and Women, and in 1933 to the honorary visiting staff of the Royal Victoria Hospital. He had begun consulting practice taking rooms in 2, Lower Crescent which were let to him by the late Miss Bostock, then a personage in the nursing profession and just retired from her position as matron of the hospital As his quite exceptional qualities became more widely known pressure of work steadily increased, and soon he was doing his full share of surgery and night emergencies at the hospital, outpatient sessions, teaching, and making long journeys at all hours into the country, often to operate on difficult cases and in hastily improvised surroundings On one occasion during an exceptionally hard winter, he had to abandon his car in a drift and proceed on foot through the snow for many miles carrying his instruments and other sterilised equipment to answer the call of a doctor in Ballyclare at the bedside of a patient with an acute abdomen

Such a life would have provided ample satisfaction for most men but between 1930–39 he found time to undertake, entirely on his own initiative many operations on the brain and spinal cord which being lengthy procedures had to be undertaken at night, and then only when a theatre was available Even so there was never any difficulty in getting volunteers to assist him and usually about 9 or 10 of an evening when preparations had been completed the operation would begin The results as is not surprising in the light of present knowledge were not always encouraging it required courage to go on, and good humour and tact to brave the often disapproving looks of the night sister at such frequent disruptions of her routine; but in time she became his staunch ally So he carried on often not leaving the hospital until 6 in the morning only to return two or three hours later (as fresh as if he had had a full night's rest) to grapple with a heavy outpatient clinic

Shortly after the outbreak of war in 1939 he volunteered for military service and accepted the invitation of the late Sir Hugh Cairns to join him and others at the Military Hospital for Head Injuries Oxford Here he worked until the conclusion of hostilities, being promoted to the rank of lieut.-colonel His exceptional skill as a brain surgeon, his phenomenal yet apparently effortless capacity for sustained physical and mental activity, and the care and thought he bestowed on the wounded men committed to his charge commanded the respect and affection of all those who worked with him. Whilst at Oxford he made some outstanding contributions to the surgery of wounds of the head which were published in the War Surgery Supplement of the *British Journal of Surgery* (1947)* The first was on Orbito-facio-cranial Gunshot Wounds and the second appeared jointly with his chief Cairns Peter Daniel, and G B Northcroft under the title of Delayed Complications after Head Wounds with Special Reference to Intracranial Infection

In 1946 he gave the annual oration to students at the opening of the hospital winter term, selecting as title for his address the Development of Neurosurgery (*Ulster med J* 1946, 15 141) At its conclusion he made the following comments the significance of which (as they applied to himself) may not have struck us then as forcibly as they now do He said

> This brief record of the contributions to neurosurgery fails to take note of the spirit which infused the daily lives of the great men who laid its foundations and built up its various departments Amongst other attributes common to them all was honesty of purpose, a simple desire for the truth and nothing but the truth" He went on: 'one might say of each of them as Shakespeare said of Brutus—'His life was gentle and the elements so mixed in him that nature might stand up and say to all the world, This was a man '

---

* Earlier pre-war publications had been Whitla's Dictionary of Treatment (8th Ed.), of which he was joint editor, and a paper on Congenital Talipes Equino Varus (*Ulster med J*, 1933) He also published a paper on Injuries of the Frontal and Ethmoidal Sinuses during the war (*Proc. R Soc Med*, 1942)

The active substance appears to be an amine with about 10-14 carbon atoms

Vegetable lecithin, from peanuts or soybean, provides a rich source of the factor

A similar, if not identical, substance is concentrated in egg yolk

The possible relationship of this factor to the work of Coburn et al (1954) on the antirheumatic properties of egg-yolk is discussed

We are indebted to Dr Knud Tolderlund, of the Statens Seruminstitut, Copenhagen, for the B C G, and to Miss M V Mussett for the statistical analysis on which our observations are based

EFFECTS OF DIVIDING THE PITUITARY STALK IN MAN

DOROTHY S RUSSELL
M A Oxfd, M D Lond, Sc D Camb, LL D Glasg, F R C P
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON
From the Bernhard Baron Institute of Pathology, the London Hospital

PUBLISHED reports on the results of dividing the pituitary stalk during intracranial operations are both few and discordant Dott (1938, case 2) recorded no untoward effects in respect of pituitary function On the other hand in Cushing's case (1912) death followed, in acute pituitary cachexia, 3 days after the operation Post mortem examination revealed that the stalk had been divided at its junction with the gland, and that the anterior lobe had undergone necrosis In 1940 Dandy reported the case, in a girl of 17, in which he had divided the stalk midway between the brain and the diaphragma sellæ Postoperatively there was permanent diabetes insipidus but no dysfunction of the anterior lobe the patient subsequently married and was twice pregnant Rasmussen's case (1940) is excluded because his description indicates that the stalk was not in fact completely divided, and, further, the *anterior pituitary* was deliberately cauterised at operation

In the present communication, illustrated by three cases, an attempt will be made to reconcile these divergent results in the light of recent investigations of the intimate vasculature of the pituitary body (Xuereb et al 1954)

Case-records

FIRST CASE

A man of 41 was operated upon *for a suprasellar craniopharyngioma* by the late Sir Hugh Cairns in 1933 For the previous 4-5 years there had been some impairment of anterior pituitary function—increase of weight impotence and lack of energy On examination he was slender and pale, with a thin wrinkled and slightly scaly skin He had a thin beard but hair was absent from the trunk and pubic hair was of feminine distribution His external *genitalia were small* A sugar tolerance test gave a low and rather flattened curve Daily intake and output of fluids varied from 1124 to 1537 *ml*

After operation, when the pituitary stalk was accidentally divided he remained stuporose with a tendency to delirium

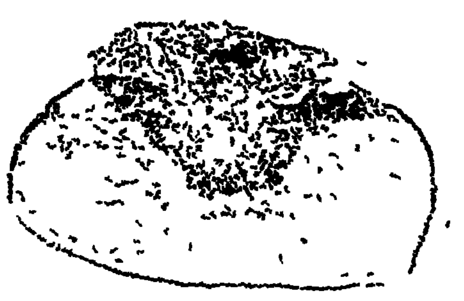

Fig 1 (case 1)—Horizontal section of pituitary showing necrosis of anterior lobe (pale) and fringe of surviving cells (dark) (Haematoxylin and eosin × 45)

He made few spontaneous movements, and developed spasticity *of* all limbs, with a transitory extensor plantar response on the right His temperature remained at 96 F except *for* two excursions above normal within the first 4 hours Pulse rate was from 100 to 120, blood pressure remained at 60/50 mm Hg, and rose only to 85/70 mm after a blood transfusion A single injection of 0 75 ml of a crude extract of whole pituitary (prepared by a commercial firm) produced a temporary rise to 110/90 mm 4 hours later

He became progressively more emaciated during the 1[illegible] days of his survival, and facial hair ceased growth though previously he had shaved daily The skin over his malar eminences became shiny and waxy Urinary incontinence *prevented any estimate of fluid output, but his daily intake* varied from 592 to 2631 ml and he was disinclined to drink

Macroscopic Examination (P M 399 1933)

At necropsy operative division of the stalk was confirmed though its remains were not identified There was a ragged gap in the floor of the third ventricle exposing the interior of the cystic tumour The sella turcica was shallow the dorsum sellæ being *greatly* eroded The pituitary body (0 35 g) was slightly *flattened, and on horizontal* section the anterior lobe appeared pale and opaque, the posterior lobe normal *The adrenals (7 4 g) and thyroid gland* [illegible] appeared normal Both testes were small (11 8 g)

Microscopic Examination

Pituitary—The *anterior* lobe is necrotic except for a narrow subcapsular zone, a few cells deep, which expands into a somewhat broader irregular strip against the junction with the posterior lobe (fig 1) Internal to this peripheral rim is a zone of young granulation tissue containing numerous foam cells The *posterior* lobe is normal apart from a slight increase in the number of pituicytes

Other endocrine organs—The *adrenal* cortex is narrow the zona glomerulosa prominent and well preserved while the nuclei of the zona fasciculata are often shrunken and pyknotic The zona reticularis is focally infiltrated with plasma cells and there is less nuclear degeneration The medulla appears normal The *thyroid is normal,* containing abundant colloid In the *testis* there is slight diffuse atrophy of seminiferous tubules, with fibrous thickening of their basement membranes Although many spermatogonia and spermatocytes are in stages of division there is no evidence of spermatogenesis, and the tubules of the rete are empty The three *parathyroid glands,* examined *appear normal*

SECOND CASE

A girl aged 8 well developed and intelligent for her age, was admitted to hospital in 1951 with symptoms and physical signs referable to a suprasellar craniopharyngioma A radical attempt at its removal was complicated by division of the pituitary stalk though this was not actually seen at operation *She survived for 33 days* during which she lay for the most part unconscious and unresponsive though she occasionally attempted to obey commands She made no spontaneous movements, but would *move slightly in response* to pinprick Flaccidity of the limbs developed, with absent reflexes Within 24 hours of the operation blood *pressure* fell to 90/60 mm, temperature rose to 102 F, and pulse and respiration rates to 160 and 70 respectively With the *administration* of pressor substances and of cortisone, and later corticotrophin, her general condition improved appreciably, *and* the blood pressure rose to 115/65 mm, though it fluctuated considerably and was sometimes too low to estimate *There was never any* n his later years, gardening, both of which he was able to njoy to the full at his charming home at Elie where he had a appy time with his family and grandchildren

Mr Jardine leaves a widow and three *daughters*

BARBARA TCHAYKOVSKY
M D, B Sc Lond D.P H

Barbara Tchaykovsky, who died in her 81st year on Feb 5, was the eldest child of Nicholas Tchaykovsky, the well-known Russian educationalist and reformer, who, under the Czarist regime, was forced to leave his country in the '70s of the last century After a period in the United States, where Barbara was born, the family came to England and settled in Harrow, which remained their permanent home She was educated at the North London Collegiate School for Girls, Bedford College for Women, and the Royal Free Hospital She was a brilliant student, and, although her medical studies were protracted because she had to earn her living by teaching and coaching, she graduated M B Lond in 1906 and M D in 1908, when she was awarded the university gold medal in State medicine She had already obtained the D P H

After qualification she was appointed a part-time school medical officer under the London County Council, a position which she held until her retirement under the age-limit in 1940 She also held appointments as medical officer to a few private schools During the whole of her professional life she gave her spare time her energies, and her means, to the furtherance of the maternity and child-welfare movement In 1912 she founded a dental clinic for the school-children of Harrow and district, at a time when there was no provision for treatment of the dental defects revealed at school medical inspections This was followed in 1915 by the foundation of the Wealdstone Day Nursery and, associated with it, the first baby clinic and antenatal clinic Her efforts were largely responsible for the establishment of the first municipal baby clinic in the district and for the formation of a special maternity and child-welfare subcommittee of the local public-health committee on which she herself served for over twenty years She also founded the Council of Child Welfare for Harrow and District, which coordinated the voluntary services dealing with antenatal, dental massage, and sun treatments an observation ward for ailing babies, *and a* clinic for child guidance It was not until 1937 that responsibility for all these activities, created largely through her personal energy and enthusiasm, was jointly assumed by the Middlesex County Council the Harrow Urban District Council, and the Harrow Hospital

H C writes "Dr Tchaykovsky was endowed with a typical Russian temperament, marked by great enthusiasm and driving power She was generous to a fault and would respond without stint from her modest resources to appeals for help She will be greatly missed by her friends, who loved her for her personal qualities and admired her for her devoted public service"

THOMAS ROBSON
M D Lond, *M R C P*

Dr Robson, senior physician to the Royal Victoria Hospital, Bournemouth, who died at his home on March 22 at the age of 54, was born in Cardiff, the son of a consulting engineer Educated at the Cardiff High School *he* began his medical studies in Cardiff and continued them at St Thomas's Hospital He qualified in 1923 and after a period as resident physician under Dr Frank Eve at the Royal Infirmary Hull, he went into practice at Royston Herts While in this general practice he took the M D Lond and M R C P In 1930 he moved to *Bournemouth* where he was for some years in partnership with the late Dr Bottomley He became physician to the Cornelia and East Dorset Hospital, Poole and was *later* appointed an assistant physician to the Royal Victoria and West Hants Hospital, Bournemouth in 1939 he became a full physician He took an active *part not only* in the clinical work of the hospital but also on its administrative side, and for some years was *vice-chairman of* the board of management He was also the secretary of the Bournemouth Medical Society

T R A writes

Tom Robson was always a bonny *fighter* Though born in Wales, his roots were in the North Tyne, the home of the turbulent Robson clan of whom Trevelyan says "they paid little heed to the things writ or even to the feudal power of the Percies' Collaterals of George Stephenson, his people were railway engineers who drove the iron roads through Britain, and this iron and this driving force were part of his nature Here indeed was a physician with the brain of an engineer, clear cut as a precision tool, penetrating to the root of the matter, all trimmings and superfluities shorn away, a brilliant diagnostician He fought to establish the position of the physician and to prevent the splitting of general medicine into too many branches He believed that when all laboratory tests had been assayed and all specialists had had their say there would always be the need for someone with a wide knowledge, not only of medicine but of life and philosophy, to give a final opinion He fought against death when it approached his patients, as if it were a personal affront, all his forces were mobilised, no time or effort was spared He rejoiced over each victory and mourned each loss His great capacity for work and his complete inability to relax finally ended in his own defeat, after a long courageous struggle against ill health "After life's fitful fever he sleeps well" He will live long in the memories of both doctors and patients in this part of the country

Dr Robson is survived by his wife and a daughter Dr Margaret Robson, and a son who obtained an open scholarship at St John's Cambridge, and is studying medicine there

Dr J E O'LOGHLEN

K B writes

In these days when it is fashionable to stress the importance of general practice, the death of Dr O'Loghlen should not pass without notice, since few of the last generation can have done more to enhance its status His versatility was remarkable He was skilled in the practice of the many minor surgical *procedures which fall* within the scope of the general practitioner—and indeed some major procedures *for his rectal* work attracted and kept patients from far afield He neglected no *specialty In medicine* his knowledge and ability were great, while a host *of* patients have reason to be grateful to him *for* his gifts in the diagnosis of orthopædic ailments of all kinds and *their* treatment, especially by manipulation His ability seemed *sometimes* to be based on a special sense, but was in reality founded on a solid basis of anatomy, the *study of which* he *continued* throughout his life

His concern was always where possible for the re education of his patients and the prevention of the faulty habits which *had led to their disease* His storehouse of advice particularly about minor ailments, was an unending *surprise* He gave his time in strict proportion to his patients needs wasting little on the idle and the trivial, but showing the utmost *concern for those* who were really ill He always kept in touch with those whom he had had to refer to a *specialist*— He wore his great kindness of heart under a cloak, but those who knew him were not misled

Mr F J F BARRINGTON

R E S writes

"*I knew* Mr Barrington because he hired my father's shooting in Norfolk and he invited me to join him on several occasions He understood the way of birds and would walk *long* distances *for them* I often thought his insistence on being on the outside had its advantages and was convinced of it when at the end of a long walk we approached a field of *kale* on the outer side of which was a strip of stubble Down this he walked a little ahead of me and at the end was as fresh as is the month of May compared with us who emerged soaked to the umbilicus and with wet mildew clinging to our jackets But all was soon forgotten as he handed round his flask remarking that he thought the risk of contagion was small I feel sure those Saturdays from September to January restored his mental energy and kept him a fellow of infinite jest of most excellent fancy ' "

P H M -B writes

Barrington was by every measure an exceptional personality As I saw his lank slim figure, hatless as usual carrying the inevitable despatch case, swinging down Harley Street before turning into Marylebone Road the night before he died, I little thought that I *had* seen the last of my old friend Although I well knew the wide field of science over which his mind ranged, it was in natural history, and especially in ornithology, that we met on common ground Snorker was a

Other endocrine organs—In the *adrenals* degeneration of the zona fasciculata resembles that described in case 1, but cellular infiltration of the zona reticularis is less conspicuous The seminiferous tubules of the *testis* have undergone slight atrophy There is no evidence of spermatogenesis the cellular picture being similar to that observed in case 1 The tubules of the rete and head of the epididymis are packed with necrotic cells and poorly preserved spermatids Apart from focal carcinomatous infiltration of the stroma, the appearances of the *thyroid* are normal and there is abundant colloid

Discussion

In cases 1 and 2 necrosis of the anterior lobe resulted from operative division of the pituitary stalk In case 2 the development of purulent leptomeningitis can be excluded as a cause in the light of the clinical history In case 3 a similar necrosis was induced by carcinomatous permeation of the portal vessels In all three, acute anterior-lobe deficiency preceded death the length of survival in cases 1 and 3 being closely similar in the absence of hormone therapy In none was there any evidence of diabetes insipidus It is, however recognised that an intact anterior lobe is essential to the development of this syndrome, though precisely how this operates is controversial

Case 3 has the merit of demonstrating the essential part played by the portal vessels of the stalk in maintaining the nutrition of the anterior lobe Experimental confirmation of this is provided by Daniel and Prichard (1956) who found that arresting the blood flow in the portal vessels of the rat by cauterisation resulted in necrosis of the anterior pituitary But, owing to certain differences in the vascular supply in the rat, these necroses were not as extensive as those observed in the present human examples Sheehan (1937) has emphasised the importance of thrombosis in the sinuses below the level of the stalk in determining the development of Simmonds's disease after obstetric shock

The degenerative changes observed in the adrenal and testis of cases 1 and 3 illustrate the effects of recent deprivation of corticotrophic and gonadotrophic hormone

Recent anatomical studies (Xuereb et al 1954, McConnell 1953) have made it clear that the superior hypophyseal arteries do not directly supply the anterior pituitary But, having entered its substance, they subdivide and certain branches anastomose with twigs from the inferior hypophyseal arteries in the neighbourhood of the lower infundibular stem (i e, that part of the stalk which lies below the level of the diaphragma sellæ) According to Xuereb et al, branches from these anastomotic segments, as well as the terminal twigs of the superior hypophyseal arteries, ascend into the lower infundibular stem and break up into capillary tufts Blood is collected from these into short portal vessels which descend into the anterior lobe and, with the longer portal vessels descending from superior levels distribute blood to the sinusoids of the gland (fig 4) The extent of the circulatory disturbance inflicted on the anterior lobe should therefore be proportionate to the de interruption of portal supply, as already postulated b Xuereb et al the lower the level of division the le extensive will be the necrosis In Cushing's case we ha the valuable information that division was at the junc of the stalk with the gland, and necrosis was minim In case 1 above it may be inferred that division was at similar level, in case 2, where more of the gland surviv it was probably higher Division, in Dandy's case, at t middle of the stalk inflicted diabetes insipidus thro interruption of the supraopticohypophyseal tract nerve-fibres, but clearly did not damage the anter lobe sufficiently to impair its function

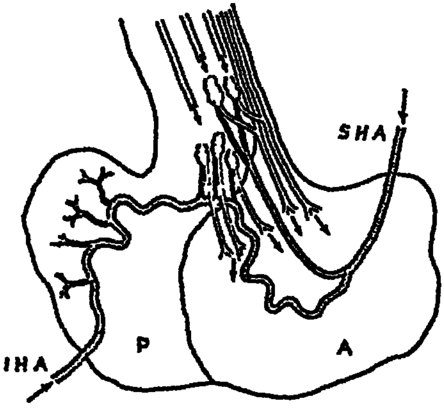

Fig 4—Diagram of relevant features of pituitary circulation (adapted from Xuereb et al) A anterior lobe, P posterior lobe SHA superior, and IHA, inferior, hypophyseal arteries The long and short portal vessels are represented breaking up into the sinusoids of the anterior lobe

At the present time hypophysectomy is performed i the treatment of advanced carcinoma of the breast Th object of the operation is to remove all anterior l tissue, and I submit that a simpler procedure—divi of the stalk at its junction with the gland, and caut of the cut segment, which should include destruction o the lower infundibular stem—may be equally effectiv If so the hazards to the patient would be reduced and th surgeon's task considerably simplified In the Londo Hospital Mr Northfield has adopted this modification i several cases, but as yet it is too soon to assess the full endocrinological effects

Summary

The effects of dividing the human pituitary stalk hav been examined in the light of three cases which came t post mortem examination, and of the existing literature

The extent to which necrosis of the anterior lobe wil result seems to depend directly upon the completenes with which the portal vessels are interrupted, and henc the level of division

It is suggested that division of the stalk at its junctio with the gland may be as effective clinically as tota hypophysectomy

I am indebted to Mr D W C Northfield for the cli notes of case 2

ADDENDUM

Since this paper was written one of Mr Northfield's cases came to necropsy two days after stalk section had been performed The gland (weight 0 8 g) was divided after fixation into eight sagittal pieces and sectioned serially Microscopically the posterior lobe is well preserved and partly occupied by secondary carcinoma The greater part of the anterior lobe is necrotic, with marginal infiltration of such tissue by neutrophil leucocytes A zone of surviving cells is closely related to the boundary between the anterior and posterior lobes an fans out laterally beneath the capsule on the postero inferior aspect of the gland The zone is irregular i outline and its lateral extensions are occasionally interrupted by the necrosis Elsewhere a thin interrupted zone, up to two acini thick, of surviving tissue lies beneath the capsule with the exception of the dorsal surface

To gain a rough estimate of the amount of surviving tissue, forty-four representative sections were projected and the living and necrotic areas outlined on paper, an these areas were then cut out and separately weighed By this means it was estimated that 8 4% of anterior lob survived This is probably excessive because degenerating cells are often mingled with those that appear we preserved

A HOSPITAL CENTENARY

THE Hospital of St John & St Elizabeth, London, this ear celebrates the centenary of its foundation It is a Catholic foundation, though the majority of its patients are on Catholics, and it is outside the National Health Service Patients are asked to pay what they can afford, and on average they contribute about £4 a week towards their total expenses of £15 Otherwise the hospital depends on voluntary contribution Admissions rose from 1783 in 1947 to 2578 in 1954 Over the same years the hospital's annual income increased from £42,000 to £92,000 and expenditure from £75,000 to £110,000 The hospital has opened a centenary appeal for £250,000 to clear the accumulated deficit, renew equipment, and provide more accommodation for training rses Donations should be sent to the fund, c/o Barclays ank, 54, Lombard Street, E C 3

MEDICAL RESEARCH IN MALAYA

THE Colonial Development and Welfare Act of 1946 was planned to promote the welfare of Colonial territories by financial grants for approved schemes The benefit to Malayan medicine from this aid has been incalculable, and its proposed extension to 1966 foreshadows continued support

The report for 1954 of the Institute for Medical Research at Kuala Lumpur is replete with information on bacteriology, serology, biochemistry, nutrition, pathology, virus research, medicine, zoology, entomology, and malariology The institute, rected by Dr J. W Field, has been linked with the Research epartment of the United States Army and Graduate School ollaboration began in 1947 with a clinical trial of chloramhenicol in the treatment of scrub typhus Since 1948 five American medical research teams, financed by the U S Treasury, have worked in the institute, and now a small American group is engaged there on the transmission of Japanese-B encephalitis, the leptospiral infections, and the efficacy of leech repellants Recent years have also witnessed increased liaison with the Army Medical Services, for which the jungle operations against Communist terrorists, the excellent hospital facilities of the Army in Malaya, and the deployment of many keen young doctors have been responsible The Army service has for the first time in Malaya isolated apanese B virus from a human infection In February, 1954, aboratories for the study of virus diseases were opened

This report gives some indication of the increasing value and amount of work undertaken at the institute

THE AMBULANCE SERVICE

CONCERNED by the increasing cost of the ambulance service (in the past three years this has risen by some 30% to about £10 million a year) and by its difficulty in meeting all demands, e Ministry of Health has made a fresh approach to hospital d local health authorities Over 60% of all calls on the ervice come from hospitals, and hospital authorities are sked to appoint a single person in each hospital to coördinate requests for ambulance transport The decision whether an ambulance or hospital car is needed should, says the Ministry,[1] be a medical responsibility, and only exceptionally should this responsibility be delegated to the nursing staff Local health authorities are asked[2] to ensure that the medical officer of health is closely associated with the ambulance service, and suggestions for more economical and efficient operation include use of radio communication and of hemmed canvas sheet stretchers with removable poles, to lift patients from an ambulance stretcher on to a hospital bed, thus saving delay of the ambulance through its having to wait for the return of its stretcher

FOUNDERS OF DERMATOLOGY

IN the Harveian oration for 1951 Sir Archibald Gray gave an account of the history of dermatology from the time of Harvey[1] He has now used the Prosser White oration to discuss the Founders of Modern Dermatology[2]

In the main he describes the work of three men—Joseph Jacques Plenck (1738–1807) who worked in Vienna, and two Yorkshiremen, Robert Willan (1757–1812) and Thomas Bateman (1778–1821) Willan came to London in 1781 and worked for more than twenty years as physician to the Public Dispensary in Carey Street where he was joined by Bateman in 1801 Willan set out to define the lesions and collate the various disorders of the skin, producing a simple classification on a morphological basis, and Bateman popularised Willan's work in a book which ran into many editions Plenck had produced a classification at an earlier date

Most of Sir Archibald's address consists in a critical and detailed assessment of Plenck's and Willan's contributions Plenck undoubtedly had the originality to introduce the morphological system of nomenclature Willan copied and clarified this, but what is more important is that he introduced a nomenclature which with some modifications has been universally accepted He, more than anyone, is recognised as the founder of modern dermatology Willan was also interested in epidemic diseases, and published annually from 1796 to 1800 monthly reports on the weather and prevailing diseases in London which is considered a pioneer work, and which was continued by Bateman from 1804 to 1816 He was partly responsible for the founding in 1801 of what afterwards became the London Fever Hospital, and was one of the original extraordinary physicians

MEDICAL FILMS

THE following films have been added to the library of th International Cripples Association

Treatment of Poliomyelitis with Curare and Stretch (16 mm, silent, black-and-white, 10 minutes U S A, 19 Victor H Raisman, M D, Kew Gardens Hospital, New Yor —This shows the improvement in a 17 year old boy un treatment with curare and stretching, at intervals from three weeks to two years after a severe attack of poliomyelitis The emphasis is on the results obtained rather than on details of the treatment, and there is no indication of the dosage of curare used This film is of interest to physiotherapists For specialists in physical medicine it includes insufficient clinical detail

Bugnet's Neurotherapeutic Method (16 mm, sound, black-and-white, 29 minutes Netherlands, 1954)—This film outlines the theory, application, and results of Bugnet's therapy for re-educating muscles after poliomyelitis It opens with a short introduction in which the principle of muscle activation by bombardment with stimuli is explained and the underlying physiology is shown on charts Examples of the use of the standing, walking, and grasp reflexes are shown The second half of the film is devoted to a series of cases illustrating the application of the technique This long film leaves no clear impression of the procedure or its advantages The exposition is muddled and the conclusions are confused

Mrs Hazard's House (16 mm, sound, colour, 11 minutes U S A Adviser Harry F Dietrich, M D)—This is a propaganda film, encouraging greater care in the prevention of accidents to children in the home

It opens with a visit to Mrs Hazard's house in which various hazards are depicted in a series of still cartoon pictures while Mrs Hazard describes the accidents she devises to change children into statistics Dr Dietrich is then introduced, and he remarks that accidents in the home cause more deaths annually than do disease or traffic accidents Finally a few examples of hazards in the American home of a young couple with an infant are shown, and the film ends by recommending that leaflets be obtained from local health authorities

Though designed for American audiences, this film might be useful in this country for selected general audiences

Further information about these films may be obtained from Dr Francis Bach 1a Devonshire Place, London W 1

TABLE II—SURVIVAL AND CONTENT OF ADENOSINE TRIPHOSPHATE CONTENT OF CELLS INCUBATED WITH NUCLEOSIDE AFTER 3 WEEKS' STORAGE RESTORED AT 4°C FOR VARIOUS PERIODS AND REINCUBATED BEFORE TRANSFUSION

Storage (days)	Nucleoside	% survival at 48 hr		Adenosine triphosphate (µg of phosphorus per ml of cells)		
				Before incubation	After incubation	
		Nucleoside	Glucose		Nucleoside	Glucose
28	Guanosine	82	48	39	58	31
42	Guanosine	75	21	30	49	nil
56	Guanosine	67	17	28	39	nil

In table II are shown similar experiments in which blood had been incubated with the nucleoside at the end of three weeks' storage and then reincubated before its final transfusion. Here again there is increased survival of the treated cells, and their survival is better after long storage periods when treated in this way, *whereas there is but little difference between the two* groups after shorter periods of storage. These experiments were *performed* on three separated specimens of stored blood, which all responded well to nucleoside revival. However, as pointed out elsewhere (Prankerd 1956) there is some variability in the metabolic response of cells to incubation with nucleosides, and recently two specimens of stored blood have been found in which there was no satisfactory revival.

Fig. 2 shows a record of blood-pressure in a narcotised cat after the intravenous administration of various amounts of the two nucleosides. The drop in blood-pressure after adenosine contrasts clearly with the absence of any *change after guanosine.* *No abnormalities* on electrocardiography were observed although such have been reported in guineapigs given adenosine (Drury 1936).

To demonstrate the *innocuity* of *guanosine* when given to man, records of pulse, blood pressure, temperature, and biochemical tests are shown in fig. 3 of a uræmic patient who was given a pint of six-week old blood revived before transfusion by an hour's incubation with 750 mg. of guanosine. Electrocardiograms were taken frequently during transfusion, and no abnormal effects observed. The patient's hæmoglobin increased by an amount compatible with complete survival of the transfused cells twenty-four hours later, and after forty-eight hours there was no indirect evidence of excessive hæmolysis.

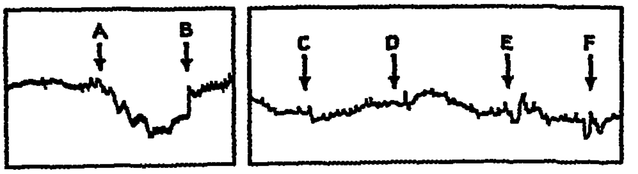

Fig. 2—Blood pressure tracings from narcotised cat. A–B, injection of adenosine 5 mg. C–D, injection of guanosine 5 mg. E–F, injection of guanosine 50 mg.

DISCUSSION

The benefit of reviving stored blood with nucleosides is clearly demonstrated by these experiments, and it appears that reasonably good survival can be obtained even in eight week old blood which has been revived after three weeks' storage and again before transfusion. The mechanism of this revival is *probably metabolic* and related to the increase in the intracellular content of adenosine triphosphate. Elsewhere (Prankerd 1956) the detailed metabolic changes taking place in stored blood have been reported, *together* with the effects of nucleosides. The conclusion from these studies was th after three weeks' storage, red cells lose their abi to phosphorylate glucose, and that this deficiency related to the decrease in intracellular adenosine t phosphate. Nucleosides enable red cells to resynth adenosine triphosphate; and, *once this has happened,* a *sufficient extent, phosphorylation* of glucose can again.

The mechanism of the nucleoside effect was disc in an earlier paper (Prankerd and Altman 1954b), which it was suggested that Dische's (1938, 19 observations were relevant. He observed that red- hæmolysates incubated with adenosine formed tr and hexose phosphates, all intermediates in the glycoly sequence. We concluded that, with intact erythrocyte the nucleosides were split by a nucleoside phosphoryla in the cell surface, and that the ribose phosph which *formed after the splitting* could be metabol by way of steps in the hexosemonophosphate shunt. These steps are shown diagrammatically below.

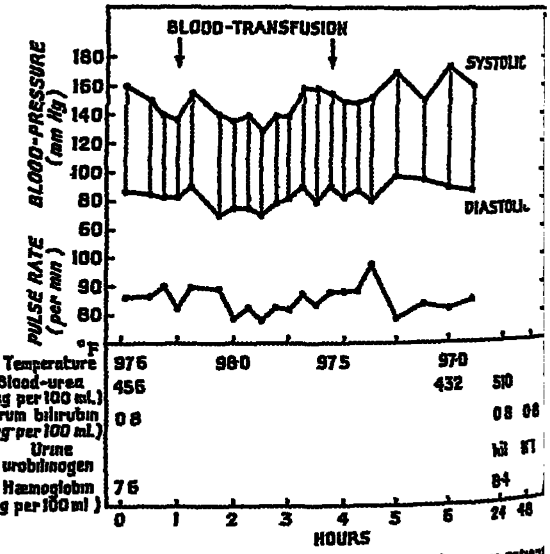

Fig. 3—Blood-pressure, pulse-rate, and biochemical changes in patient transfused with six-week-stored blood revived with guanosine.

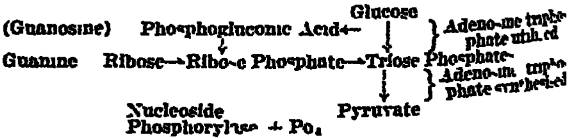

Glucose
(Guanosine)
Phosphogluconic Acid
Adenosine triphosphate utilised
Guanine
Ribose
Ribose Phosphate
Triose Phosphate
Adenosine triphosphate synthesised
Nucleoside Phosphorylase + PO4
Pyruvate

The really significant point seems to be that, where adenosine triphosphate is required for the phosphoryla tion of glucose, it is not required with the ribose of th nucleoside, and it can therefore be resynthesised eve when the cell stores are severely depleted of it.

The chemical structures of adenosine and guanosi are shown in fig. 4, and the difference in toxicity betwee the *two seems to* be related to the chemical differen between them. The substitution of the amino group between them. The substitution of the amino group the 6th carbon of adenosine by oxygen in guanosi may account for the loss of toxicity. A number of oth nucleosides not showing this *amino group* have also be

MIDDLESEX HOSPITAL, LONDON

THE breast has at least two primary lymphatic drainage systems, the larger the axillary, the smaller the internal mammary Whereas the axillary nodes are invaded in about two thirds of patients with "operable" carcinoma of the breast, the internal mammary chain is involved in one-third (Handley and Thackray 1954) The classical radical mastectomy, which takes account only of the axillary system, is therefore foredoomed to failure on one occasion in three by reason of its neglect of the internal mammary lymph-nodes

Surgeons in an endeavour to deal with this unsatisfactory situation have, among other expedients, attempted to make breast surgery truly radical by excising both primary lymphatic drainage systems at the same time as the primary growth We describe here a simple technique for such an operation, and its immediate results in 57 cases There must of course be a lapse of some years before the late results can be assessed, but the present analysis shows that the internal mammary chain can be extirpated without significantly adding to the mortality, morbidity, or deformity of the classical operation

Technique

Several techniques have now been described for excising the internal mammary chain as an addition to "radical" mastectomy The method to be described differs from these chiefly in that it preserves the whole pectoralis major muscle

The operation begins with the same skin incisions as a radical mastectomy Thin skin flaps are raised to the usual limits of the proposed excision At the inner and upper corner of the wound the fascia is then reflected downwards and outwards off the pectoralis major muscle, sufficiently to allow this muscle to be split in the direction of its fibres over the first intercostal space A biopsy of the underlying internal mammary lymph-node is then made by incising the muscles of the 1st intercostal space, to discover whether the node is invaded by carcinoma If it is, the operation is terminated as a simple mastectomy If it is not, the internal mammary vessels are double tied as high as possible (a process which is facilitated by nibbling away the lower border of the first costal cartilage) and divided The first space is then left for the moment, and the reflection of the pectoral fascia and breast from the pectoralis major proceeds as far as the lower border of the muscle By lifting the arm so that it points towards the ceiling and by retracting the pectoralis major, the pectoralis minor can be sectioned close to the coracoid process, and at its lower attachment, and the axillary contents cleared in the usual way up to the lateral border of the first rib , the pectoralis major with its main nerve supply is preserved The breast, with its attached axillary tissue, is removed as a specimen similar to that from a classical radical mastectomy, except that it lacks the pectoralis major muscle

The arm is replaced on an arm board and the sternal head of the pectoralis major is divided just lateral and parallel to the edge of the sternum to reveal the costal cartilages and intercostal muscles The fifth costal cartilage is removed and the internal mammary vessels are double tied and divided at their lower end

A block of the chest wall, measuring about 4 in by 1 in and including the second, third, and fourth costal cartilages, the intervening intercostal muscles, and the internal mammary vascular bundle, has now to be removed, if possible without opening the pleura The first intercostal space is re entered and the pleura gently pushed by blunt dissection away from the inner side of the chest wall as far down as possible , it may sometimes be torn in this manœuvre The costal cartilages are divided at their medial and lateral ends by slipping a Kocher's enucleator under them one by one, and cutting them with a solid scalpel Alternatively the lateral edge of the sternum may be shaved off with a Lebsche chisel to free the medial ends of the cartilages A little further dissection frees the specimen, and until it is removed there are a few small vessels which cannot be adequately secured When hæmostasis is complete the cut edges of the sternal head of pectoralis major are reunited with mattress sutures, and the gap in the chest wall thus closed The skin is sutured and drainage provided only for the axilla grafting being used if necessary

Figs 1–4 show the main points of the operative technique

The chest wall dissection adds approximately half an hour to the time taken for a Halsted operation

Results

We have now treated 57 patients by some form of therapeutic removal of the internal mammary chain The earlier cases did not always follow the description given 3, for example, were done by Urban's technique,

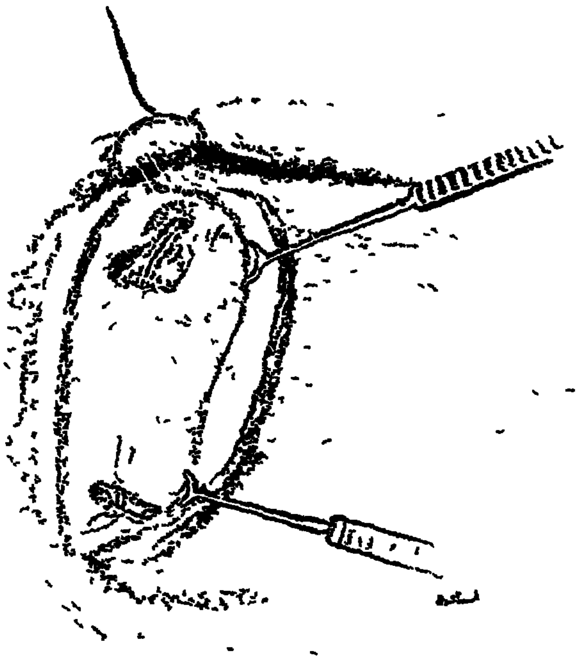

Fig 1—The breast and axillary contents have been removed and the pectoralis major muscle has been cut across the direction of its fibres, to reveal the costal cartilages The first and fifth intercostal spaces have been opened and the internal mammary vessels double-tied in the spaces

Experiment II

An attempt was therefore made to obtain 20 samples of liquor amnii in this way Patients who agreed to submit to the test were selected for paracentesis between the 32nd and 36th weeks of pregnancy if there seemed to be sufficient liquor amnii present to allow a sample to be taken safely 3 patients with obvious hydramnios were included in this number Samples were taken with a lumbar-puncture needle inserted through the abdominal wall in the midline just below the umbilicus after the injection of a small quantity of 1% procaine, 5–10 ml of fluid was withdrawn

Results —Paracentesis yielded suitable samples in only 13 of the 20 patients In 3 patients no liquor was aspirated at all and the attempt was not persisted with, in 3 others a little bloodstained fluid alone was obtained, which was considered unsuitable for examination, in 1 patient 2 ml of pure blood immediately filled the syringe when the plunger was withdrawn, and this attempt also was abandoned, 1 patient from whom bloodstained fluid alone was withdrawn began at once premature labour at 36 weeks' gestation Examination of the 13 samples obtained successfully enabled the sex of the fœtus to be diagnosed correctly in all (6 male, 7 female) In these samples relatively more cells suitable for study were observed than in samples taken by artificial rupture of the membranes later in pregnancy

Discussion

It seems clear from these results that, by careful examination of the nuclei of epithelial cells contained in specimens of liquor amnii, the sex of the fœtus can be accurately predicted Difficulties in interpretation were due to cell shrinkage simulating sex-chromatin masses and to debris partly obscuring nuclear details The number of nuclei unsuitable for study was sometimes great, the search for sufficient nuclei with good definition being then more arduous and time consuming, in 2 of the specimens examined sufficient suitable nuclei could not be found to allow a prediction to be made On the basis of such a small study it is impossible to assess how often these unsuitable specimens might be obtained

For the test to have any practical value, however, it is necessary for the liquor to be obtained with perfect safety some time before term No method of doing this other than by paracentesis uteri seems possible, and the small risk involved in the manœuvre seems to preclude this method for widespread general use The theoretical risk of injury to the fœtus or the placenta, or even the uterus, in introducing a needle through the uterine wall in this manner can readily be appreciated, and the untoward incidents in the 20 paracenteses, though they cannot be regraded as serious, were the deciding factor in the decision not to pursue this investigation further Neither the aspiration of pure blood nor the onset of premature labour was followed by serious consequences, but their occurrence indicates that there is a risk, albeit very small, from this procedure No risk at all can be justified for the purpose of predicting what will soon be known for certain

Summary and Conclusions

The discovery that genetic sex can be diagnosed on the presence of chromatin masses in female nuclei in human tissues suggested that this test might be applied to diagnosis of the sex of the fœtus before birth

Accordingly 20 specimens of liquor amnii were obtained between the 26th and 42nd weeks of gestation by artificial rupture of the membranes or at cæsarean section, and the centrifuged deposit was examined after staining

The sex of the fœtus was correctly diagnosed in 18, the 2 others were unsuitable for accurate prediction

To test the practicability of using this method to determine the sex of the fœtus before birth, 20 other patients were selected for abdominal paracentesis between the 32nd and 36th weeks of pregnancy

Only 13 suitable samples of liquor amnii were obtained and the sex of the fœtus was predicted correctly in all—6 male and 7 female

In the remaining 7 cases no liquor was obtained at all from 3, a small amount of bloody fluid from 3, and pure blood from 1, 1 of these patients went at once into premature labour at 36 weeks' gestation

Although these incidents were not followed by serious consequences they seem to indicate that the method involves a small risk, mainly to the fœtus, and is therefore unsuitable for general use to discover a child's sex which would soon be known for certain

TRACTION-MANIPULATION AND PLASTIC CORSETS IN THE TREATMENT OF DISC LESIONS OF THE LUMBAR SPINE

G K McKee
F R C S
CONSULTANT ORTHOPÆDIC SURGEON, EAST ANGLIAN REGIONAL HOSPITAL BOARD

MANIPULATIVE surgery has been looked on with misgivings by most doctors because it has been largely in the hands of unqualified practitioners, some of whom have made unfortunate mistakes, such as loosening up a fixed tuberculous hip joint Such mistakes will continue to be made so long as the initial diagnosis is in lay hands Careful clinical diagnosis, including radiography, to exclude any more serious underlying condition is essential in every case before any manipulation is undertaken

Various forms of manipulation for disc lesions have been practised—usually hyperextension sometimes combined with rotational movements and sometimes with traction

Traction is undoubtedly the safest, it may be applied by simply making a patient hang by his arms from a horizontal bar This procedure often eases the pain, but traction applied through harness attached to the patient's thorax and pelvis, with the patient prone, is much less exhausting and can therefore be applied longer The degree of traction can be controlled by a spring balance

The ability to place the patient in hyperextension while the traction is still operating is an additional help in the manipulative reduction of a prolapsed disc

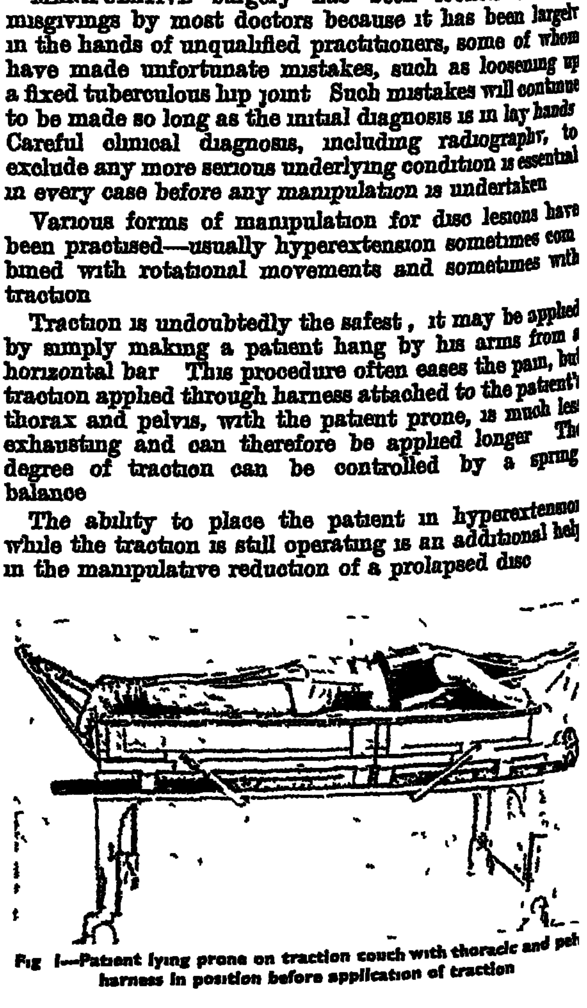

Fig 1—Patient lying prone on traction couch with thoracic and pel harness in position before application of traction

TABLE II—INCIDENCE OF INTERNAL-MAMMARY-NODE INVOLVEMENT BY INTERCOSTAL SPACES

—	Right breast	Left breast	Total
Invasion of first space node	3	10	13
Invasion of second space node	4	9	13
Invasion of third-space node	3	4	7
Invasion of fourth-space node	2	2	4
Total cases with internal mammary node invasion	11	12	23
Total cases in the series	29	28	57

37 spaces were invaded in 23 cases

substantial increase in the disability or postoperative complications over what may be expected from the standard radical mastectomy It is very difficult to put the comparison into figures because these cases have been followed with greater care than ordinary radical mastectomies and we have no exact yardstick for com- rison But the following details are not based on mere mon but are arrived at with the detailed case notes iore us

Shock —There is slightly more shock in these patients ian after ordinary radical mastectomy but it has ever caused anxiety Rather more of the cases receive wo pints of blood after operation than after radical mastectomy, but some have needed none The added loss of blood at operation has been so small that it cannot be considered to have seriously affected transfusion needs

Pulmonary Complications —These are slightly more common than after radical mastectomy, but here again no serious concern has been caused Small effusions and small areas of collapse have been noted and 2 patients have had small pulmonary emboli It must be said on the one hand that the chest was very carefully watched in this series and more minor complications have thus perhaps been found and on the other hand that vigorous preoperative and postoperative breathing exercises, tipping and chest percussion may have reduced the incidence of complications

Wound Complications —There has been less trouble from flap sloughing and marginal necrosis than after the standard radical mastectomy This may in part be due to exclusion of the very old and of those with very advanced growths and in part to our removing as a routine more skin than is usual with the corollary of frequent skin-grafting In fact, no less than 39 cases were skin-grafted

Fluid Collections under the Flaps —These have not been more evident than after a standard radical mastectomy The routine use of suction drainage has in any case made fluid collections after breast operations much rarer than they used to be

Complications of the Chest Wall Defect —These have not been seen The patients do not complain of pain in the area of the defect nor of discomfort

Arm Movement —The return of arm movement is always slower if the sternal head of pectoralis major is preserved than if it is sacrificed It is slower still if the pectoralis major is divided as we have described to expose the intercostal spaces There is thus a definite drawback in slowness of recovery in arm movement The ultimate result nevertheless seems to be nearly as good as with our standard radical mastectomy Division of the pectoralis major does not appear to result in ischaemic contracture of either portion of the muscle, but one would like further experience before concluding that

TABLE III—FOLLOW UP TO SEPTEMBER 1955

—	1–3 mos	4–6 mos	7–12 mos	13–18 mos	19–24 mos	25 mos and over	Totals
Alive without recurrence	10	4	12	14	2	4	46

D X R = deep X ray therapy

extent in the first few days but then gradually subsided Partial immediate relief occurred in 36 (72%), 14 of these had more than one manipulation, and in 6 a considerable degree of pain returned later An operation was eventually required in 4 No immediate relief was obtained in 1 case (2%) and so this form of treatment was discontinued 2 cases (4%) were made worse as soon as the traction was applied, it was immediately discontinued, and the aggravation ceased Anæsthesia was not used in any of these cases, the patient's response is probably a safeguard against doing any harm in unsuitable conditions

Of the 50 patients 44 had a temporary lumbar support made, and this is considered a great safeguard against recurrence The results after 6–12 months (table II) showed that the 11 patients who were completely relieved immediately had no recurrence, and of the 36 who obtained partial immediate relief only 6 had a recurrence

TABLE I—EFFECTS OF TRACTION AND HYPEREXTENSION IN 50 CASES OF SEVERE LOW-BACK AND SCIATIC PAIN

Effect	No of cases	Remarks
Complete immediate relief of pain	11 (22%)	In 5 of these cases the pain returned to a slight extent in a few days but then gradually subsided
Partial immediate relief	36 (72%)	14 of these had more than 1 manipulation In 6 a considerable degree of pain returned later, and in 4 operation was carried out
No immediate relief	1 (2%)	Treatment discontinued
Made worse	2 (4%)	Traction discontinued immediately
Cases in which some form of plaster plastic, or other disc support was also used	44 (88%)	Used in nearly all the later cases as a preventive measure against recurrences

The series is small but it gives some idea of the effectiveness of traction in relieving severe attacks of backache and sciatic pain It is a very useful treatment, much to be preferred to rest in bed and "twilight sleep," and, combined with a supporting corset, allows the patient to be up and about with a considerable margin of safety against a recurrence This manipulation and the application of the plastic support are usually done in the outpatient department, thus freeing hospital beds for other patients

Plastic Supports for Lumbar Spine

Plastic supports moulded directly on to the patient are used in the treatment of disc lesions either with or without manipulation, and have many advantages over plaster or any other form of support or belt for this purpose

The method of application is that described by Brennan (1954, 1955) using polyethylene as a supporting material and a heat insulated layer of polyurethane which not only prevents the patient from being burnt but also makes an excellent soft lining material for the support

Plastic Corset

Design —The design of plastic support (figs 6–8) used at Norwich is based on that of a disc support previously used by me and is made with a solid back-piece The front is narrower than the back and is split in two to allow the support to be removed and reapplied Two straps and buckles are attached in front to keep it snugly in position and to allow for adjustment This front portion is particularly important because, when the two halves are buckled together, it restricts forward flexion at the lumbar spine far better than does any posterior support alone Large pieces are cut out at the sides not only to make moulding easier but also to allow adequate ventilation

TABLE II—RESULTS SIX MONTHS OR LONGER AFTER MANIPULATION

Result	No of cases
Completely relieved	11 (22%)
Relieved to a considerable extent but still avoiding lifting heavy weights	30 (60%)
Not relieved	9 (18%)

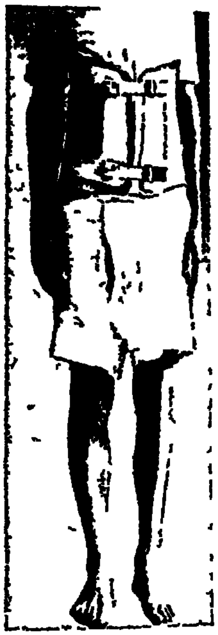

Fig 6—Patient standing with plastic support buckled snugly in position

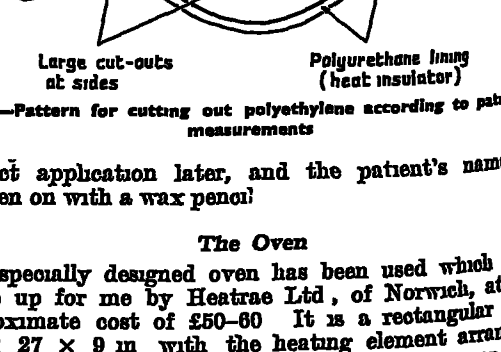
Material —The support is cut out of a $^3/_{16}$ inch sheet of polyethylene lined with a $^1/_4$-inch sheet of polyurethane of a slightly larger size so as to overlap the polyethylene by $^1/_2$ inch at the edges

Measurements —Individual measurements are required for each patient, and the corset is cut out before it is applied The circumference of the patient's body is measured at the level of the xiphisternum (upper margin of the support) and at the level of the tips of the greater trochanters (lower margin) These measurements should be reduced by $^1/_2$ inch when the polyethylene is being cut so as to allow for a gap in front for adjustment with the straps and buckles The front is $1^1/_2$–2 inches less in depth, the lower margin in front being concave downwards on each side to clear the thighs when the patient sits down The midline posteriorly is marked to facilitate correct application later, and the patient's name is written on with a wax pencil



Site for rivets for attaching straps and buckles
Polyethylene
Large cut-outs at sides
Polyurethane lining (heat insulator)

Fig 7—Pattern for cutting out polyethylene according to patient's measurements

The Oven

A specially designed oven has been used which was made up for me by Heatrae Ltd, of Norwich, at an approximate cost of £50–60 It is a rectangular box 58 × 27 × 9 in with the heating element arranged in the roof to give even distribution of heat over the floor At one side is a four-position switch giving hot, medium, low, and off, and there are also a thermostat control and a thermometer *One side of the oven is* hinged to form a door The oven is large enough to hold an asbestos-covered aluminium tray 49 × 25 in, on which the plastic material is placed The oven takes about a quarter of an hour to reach, with the switch in the d it might properly be called "rational radical mastectomy" The term "extended radical mastectomy" ight be reserved for those procedures in which attempts e made to remove more than the primary lymphatic ainage areas—e g, where a supraclavicular dissection included.

Rational radical mastectomy is still experimental hether it will improve the results of treatment remains) be seen. All that can be claimed at present is that the rocedure rests on a sound theoretical basis and can be arried out with no significant addition to the mortality, orbidity, or deformity of the Halsted operation

Summary

A new technique is described for excision of the ternal mammary lymph nodes in primary operations or carcinoma of the breast

57 patients have been operated upon without mortality, n 55 the primary tumour was either in the inner hemisphere or in the central area of the breast

The disability, deformity, and morbidity of the operation are no greater than after the classical radical mastectomy

Invasion of the internal mammary lymphatic chain was ound in 23 cases (40%)

It will not be possible to assess the value of the operation in terms of cure-rate until further time has elapsed

We are greatly indebted to the Bland-Sutton Institute of Pathology of the Middlesex Hospital Medical School, and in particular to Dr A C Thackray, for the histological work incorporated in this paper, and to Miss E Hewland, the hospital medical artist, for the drawings of the operative technique

> "Men meet together for many reasons in the course of business They need to instruct or persuade each other They must agree on a course of action They find thinking in public more productive or less painful than thinking in private But there are at least as many reasons for meetings to transact no business Meetings are held because men seek companionship or, at a minimum, wish to escape the tedium of solitary duties They yearn for the prestige which accrues to the man who presides over meetings, and this leads them to convoke assemblages over which they can preside Finally, there is the meeting which is called not because there is business to be done but because it is necessary to create the impression that business is being done Such meetings are more than a substitute for action They are widely regarded as action The fact that no business is transacted at a no business meeting is normally not a serious cause of embarrassment to those attending Numerous formulas have been devised to prevent discomfort Thus scholars, who are great devotees of the no business meeting, rely heavily on the exchange of ideas justification To them the exchange of ideas is an absolute good Any meeting at which ideas are exchanged is therefore, useful This justification is nearly ironclad It is very hard to have a meeting of which it can be said that no ideas were exchanged'—J K GALBRAITH, *The Great Crash, 1929* London 1955

A AND B BLOOD-GROUP ANTIGENS ON HUMAN EPIDERMAL CELLS

DEMONSTRATED BY MIXED AGGLUTINATION

R R A COOMBS
Ph D Camb, M R C V S
ASSISTANT DIRECTOR OF RESEARCH

DONALD BEDFORD
RESEARCH ASSISTANT

DEPARTMENT OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE

L M ROUILLARD
M A Camb, F R C S E
CONSULTANT PLASTIC SURGEON, UNITED CAMBRIDGE HOSPITALS

STUDIES of the antigenic structure of body cells other than red cells have awaited the development of new methods The technique reported here for demonstrating intra-species differences in the antigenic structure of human epidermal cells offers certain possibilities

Isolated epidermal cells or aggregates of these cells prepared from small sheets of split skin do not give cellular suspensions suitable for agglutination tests The inhomogeneity of the suspension, the irregular shapes of the cells, and the difficulty in obtaining suspensions in sufficient quantity militate against the use of this reaction On the other hand if it were possible to obtain a specific link or attachment between antibodies combining with even a few epidermal cells and different but specially selected indicator cells, the interaction of the individual cells should be easy to observe under the microscope Such specific mixed agglutination or combination between two cell types should occur if both cell types possess a particular antigen in common For instance, Wiener and Herman (1939) showed that horse anti pneumococcus type-14 serum would form mixed agglutinates between type-14 pneumococci and human red cells because both these cells possess a common antigen

If skin epidermal cells of a person of blood-group A possess the A antigen, then accepting that ordinary agglutinating antibodies are at least bivalent, we would expect such epidermal cells to be capable of being linked by anti A to group A red cells Thus on theoretical grounds the phenomenon of specific mixed agglutination or combination should provide a means of revealing whether epidermal cells do in fact contain the A and B blood group antigens on their membranes

The procedure which we have adopted for testing epidermal cells for the A (and B) antigen is illustrated diagrammatically in fig 1 A suspension of epidermal cells from a group-A person is exposed to anti-A, and the cells are subsequently washed free from uncombined antibody Only epidermal cells possessing the A antigen should adsorb anti A and consequently after being washed possess free extending "receptors" with affinity for the A antigen Group-A red cells added at this stage should combine with extending anti A receptors on the treated epidermal cells On the other hand, group-B and group-O red cells should not adhere to the treated epidermal cells

The results recorded here substantiate this reasoning and appear to offer conclusive evidence for the existence of the A and B antigens on epidermal cells of group-A and group-B persons respectively

Materials and Methods

Preparation of Isolated Epidermal Cells from Human Skin

The skin available for this study consisted of small fragments of stored thin split skin procured for plastic

Thrombotic micro-angiopathy was first described by Libman and Moschcowitz in 1925, but it was not until Baehr et al (1936) published four cases that it was generally accepted as an entity Since then there have been an increasing number of reports, mainly from the U S A In the United Kingdom two cases were reported by Symmers (1952), who reviewed the previously published cases, and Revill and Wilson (1954) reported a case which they said was the sixth in this country Ellison and Lloyd (1954) have since added a seventh

We report the present case in the hope that, along with future reports, it may help to establish a full clinical picture, elucidate the nature of the occlusive material (which we believe may be fibrin), and eventually reveal the ætiology of this strange disease

Case-report

A housewife, aged 46, was admitted to the Western Infirmary, *Glasgow*, on *June 9, 1954*, having been ill for six days She had previously been healthy except for "kidney trouble and high blood pressure" during pregnancy at the age of 28 Her menstrual history was normal, and the last period was in November, 1953 There was no history of anæmia or of excessive bleeding, but she said that she "bruised fairly easily" She had not received sulphonamides, 'Sedormid,' or any other drug known to cause purpura Six days before admission she suddenly felt dizzy and almost immediately lost consciousness She recovered in a few seconds and vomited a fairly large quantity of fluid but did not notice its colour or its consistence During the rest of the day she felt weak, breathless, and light headed Next day she had another attack of dizziness but did not lose consciousness, although "everything seemed to go black" She was seen that day by her doctor, who noted that her blood pressure was 160/95 mm Hg No petechiæ were seen on this occasion Three days before admission the patient passed a fairly large quantity of bright red blood per vaginam No clots were seen The bleeding was accompanied by indefinite right sided lower abdominal pain Two days before admission she had another attack of dizziness On the morning of admission to hospital her doctor saw her, recorded a blood pressure of 120/80 mm Hg, and noted increasing pallor, continuing vaginal bleeding, and petechiæ on her arms and body He arranged for her immediate admission to hospital

On examination the patient was well developed, obese, and very pale and her conjunctivæ were faintly tinged with jaundice She had slight dyspnœa, but no cyanosis or œdema A few scattered petechiæ were present in the skin of her forearms, arms, trunk, and legs, but not on the face or in the mucosa of her eyes and mouth There was no clubbing of her fingers Her temperature was 98°F, pulse rate 110, and respirations 22 a minute Her pulse was of good quality and regular rhythm, her blood pressure 120/75 mm Hg, and her apex-beat impalpable, no cardiac abnormality was detected clinically No abnormality of her respiratory system was detected except a few low pitched rhonchi at the left lung base Her tongue, palate, and fauces appeared normal No hepatic or splenic enlargement or any other abdominal abnormality was detected Her pupils were rather small but responded normally, both directly and consensually, to light and near vision Her biceps, triceps, supinator, and knee and ankle jerks were normal, abdominal reflexes absent, and plantar responses both flexor Motor and sensory functions were normal, except that the vibration sense was diminished in both legs There was no evidence of involvement of the cranial nerves

Laboratory investigations—No abnormality was detected in her urine A blood examination showed Hb 35% (Sahli) = 4 9 g per 100 ml, red cells 1,900,000 per c mm, packed cell volume 19%, mean corpuscular volume 100 c µ, mean corpuscular Hb concentration 25 8%, and white cells 8200 per c mm A blood film showed anisocytosis and poikilocytosis, with a few large forms and a few normoblasts White cells were numerous, with a high proportion of bilobed and trilobed neutrophils No platelets were seen, after extensive search Hess's test was negative Bleeding time 13 minutes (Duke's method) Clotting time $4^1/_2$ minutes (capillary method) Direct Coombs test negative The serum was slightly icteric

Sternal marrow puncture on June 10, 1954, revealed a hyperplastic marrow with essentially macronormoblastic erythropoiesis There was an increased number of megakaryocytes some having pyknotic nuclei The cells which exhibited granularity of the cytoplasm only rarely showed the granular material which is the preliminary stage of platelet formation. No hyalinisation of the cytoplasm was seen

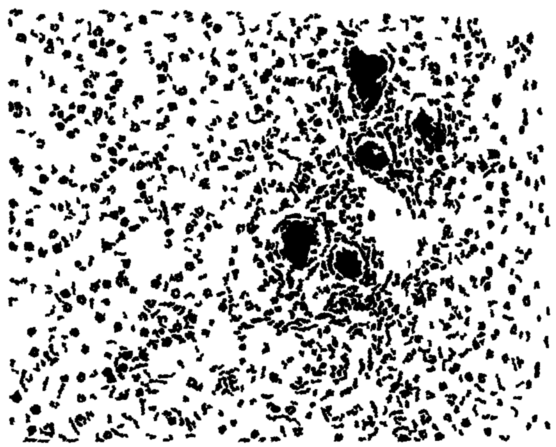

Fig 1—Thrombi in vessels of portal tract.

Treatment and course—A blood transfusion of 2 pints of group B Rh positive blood was given without any untoward reaction on June 10, 1954 Next day the patient became suddenly comatose after a tonic convulsion with cyanosis A few moments after the onset of coma she was breathing stertorously, and all four limbs were completely flaccid Her reflexes were depressed and her plantar responses equivocal Her pupils were contracted but reacted to light There was no nuchal rigidity Retinoscopy revealed no abnormality Lumbar puncture produced crystal clear cerebrospinal fluid under considerable (unmeasured) pressure, no cells were found in the fluid The patient did not regain consciousness *Left hemiplegia was suspected, but there was no definite proof* of this The patient's temperature rose to 101°F that evening

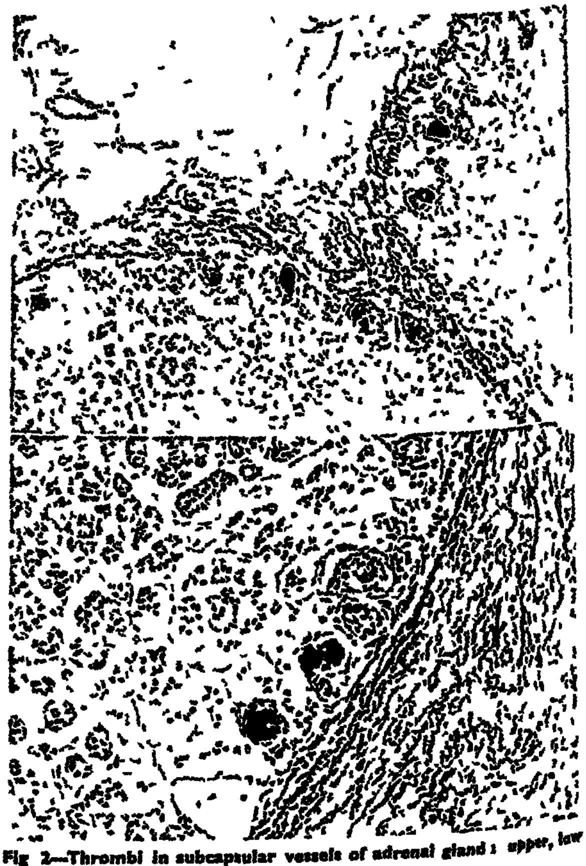

Fig 2—Thrombi in subcapsular vessels of adrenal gland : upper, low power ; lower, high power

incubated for an hour at room-temperature The epidermal cells were then deposited by centrifugation at 1500 r p m for five minutes, washed twice with N R S diluent, and finally resuspended in four drops of the diluent One drop of each suspension was then transferred to three precipitin tubes (5 × 50 mm), and one drop of a 1/2% suspension of group A, group-B, or group-O red cells was added The contents of the tubes were mixed and the cells deposited by centrifugation at 1500 r p m for two minutes The deposited cells, after gentle resuspension, were examined by phase-contrast microscopy for specific linking of red cells to the epidermal cells (figs 2 and 3)

The accompanying table, which summarises the esults, shows that group-A red cells showed a specific ffinity for epidermal cells from group-A persons only nd only if these epidermal cells had been exposed previously to an anti-A grouping serum Thus, anti-A is adsorbed on to epidermal cells of group-A persons only Likewise with group-B red cells, mixed agglutinates were formed with epidermal cells from group B persons only and again only if these latter cells had been exposed previously to anti-B grouping serum Thus anti-B is adsorbed on to epidermal cells of group-B persons only

MIXED ERYTHROCYTE EPIDERMAL CELL AGGLUTINATION BY MEANS OF ANTI A AND ANTI-B GROUPING SERA

Epidermal cells from persons of group	Exposed to grouping serum	Treated epidermal cells washed and 1 drop added to 1 drop red cell suspension of group		
		A	B	O
A	anti A	+ +	–	–
B	anti A	–	–	–
O	anti A	–	–	–
A	anti B	–	–	–
B	anti B	–	+ +	–
O	anti B	–	–	–

+ + mixed erythrocyte epidermal cell agglutination—i e, many red cells adhering to isolated epidermal cells (see fig 3*a* and *b*)
–, no mixed agglutination (see fig 2*a* and *b*)

Up to now epidermal cells from nine group-A persons, five group-O persons, and three group-B persons have been examined, and in all instances the results have conformed with those shown in the table From this it may be concluded that epidermal cells contain the A and B group antigens on their membrane

The anti-A and anti-B grouping sera used in these tests had titres of about 256 and, in most of the experiments, were used undiluted and diluted 1 in 5 However, even with the sera diluted 1 in 50, the reaction still took place, but it was weaker

If at the end of the test the deposited cells are resuspended too violently, the specifically adhering red ells may break away from the epidermal cells These ed cells, however, sometimes remain agglutinated, uggesting that some antibody molecules are transferred totally from the epidermal cells to the red cells

Among the skins examined and found to possess the group antigen, two (one group-A and one group-B) were from persons who were non secretors, hence the occurrence of the A or B group antigen on epidermal cells is not limited to persons possessing the secretor gene On the other hand, the epidermal cells from one group-A person gave a reaction much weaker than the others A second test gave the same results Whether this is the expression of an A subgroup will emerge from further experience

The tube which has group O red cells added serves as a good control for any non-specific combination or agglutination As an example, in one test epidermal cells were used which had been left as a saline suspension at 4°C for a week These cells were from a group-A person and after treatment with anti-A combined with group B red cells as well as those of group A but much more weakly However, group-O red cells were likewise adsorbed This indicated that something was wrong, and when the epidermal cells were examined carefully under the microscope they were seen to be highly contaminated with bacteria

Discussion

The only report we have seen about the A and B antigens and skin is that of Yosida (1928), who concluded that these antigens were absent from skin epithelium. The evidence presented now leaves no doubt that these antigens are present on skin epidermal cells

This finding is not without bearing on the problem of skin homografts Skin cells will now be further examined with sera specific for the other blood group systems, and an attempt will be made to establish their full antigenic structure and to determine which of the intra species antigens are concerned in the homograft reaction

The present observations seem also to be of importance in forensic medicine, because it may be possible to identify the A B O group of an isolated piece of skin completely devoid of blood

We have already applied this principle of mixed agglutination to confirm the presence of the A and B antigens on platelets (Coombs and Bedford 1955), and it seems that the method could be applied to most tissue cells It may therefore afford a useful tool in studies of the antigenic architecture of tissue cells and of problems of ontogeny

With the method described here the antigen being studied on the tissue cells must also exist on the indicator red cells The principle of mixed agglutination, however, may still be used in dealing with an undefined tissue antigen, because recourse may be had to the anti-globulin reaction Here the indicator red cells must also be sensitised with antibody globulin With both tissue cells and indicator red cells sensitised with antibody globulin, mixed agglutination may be brought about by an anti-globulin serum Coombs et al (1956) have used this latter principle in the examination of sera for platelet antibodies In this particular instance the reaction is called the mixed erythrocyte platelet anti-globulin reaction

Summary

The A and B antigens have been demonstrated on skin epidermal cells of group-A and group-B persons respectively by the principle of specific mixed agglutination

Mixed erythrocyte epidermal cell agglutination is possible because both cell types possess a common antigen

R R A C would like to thank both the Nuffield Foundation and the Agricultural Research Council for a joint personal grant We would specially like to place on record our thanks to Dr and Mrs K Joysey and Mr Walter Hatton, group B persons who volunteered skin biopsies for these experiments, to Sister M J Davies and the staff of the ear, nose, and throat theatre, Addenbrooke's Hospital, for their most helpful coöperation at all times, and to Mrs C M Madin Miss M A. Coad, and Mr R H. Matthews for numerous samples of blood Fig 1 was prepared by Mrs C M Madin

(2) Fibrin was obtained from an inflammatory exudate of lung and fixed in formol corrosive sublimate, and paraffin sections were prepared This material is subsequently referred to as natural fibrin

(3) "Thrombi" from vessels in the present case Sections of liver were used, and the material in the vessels henceforth is called the occlusive mass

Sections of platelet mass, natural fibrin, and the occlusive mass were stained by various methods under identical conditions Unless stated otherwise, the acid and basic dyes were used in 0 5% aqueous solution

Results

The results are shown in the accompanying table

The sections from the mass of prepared platelets showed a rather granular conglomerate mass of material without any recognisable structures It is, therefore, not surprising that the certain recognition of platelets in tissue sections has been a subject for much argument in the past

The picro Mallory technique stains the platelet mass blue, whereas both natural fibrin and the occlusive mass are stained red The other stains show similarities in the stain reactions of the occlusive mass, platelet mass, and fibrin It is, however, probably unjustifiable to correlate the staining reactions seen in sections of tissue with any of the materials isolated from fresh blood fixed, processed, and embedded as described, since the regulation of artefacts is difficult to control Thus, for example, if prepared platelets are contaminated with heparin or dextran, their stain affinities are much altered Likewise the staining characters of fibrin may be altered by washing before fixation

What, then, can be said of the occlusive masses that characterise this hyperergic micro angiopathy? The current view that they are composed of platelets is difficult to disprove because of the difficulty in recognising platelets in tissue sections So far as identification is possible by the use of staining methods on sections, we see no reason to regard these masses as other than fibrin The contrary views (see below) may well have been based on staining methods and methods of fixation rather less satisfactory than those of Lendrum for the demonstration of fibrin

Discussion

The anæmia present in this disease has been generally reported as hæmolytic but with a negative Coombs test, and certainly antibodies to erythrocytes were not demonstrable in the present case The fate of transfused red cells in this disorder has been studied by Adelson and Stefanini (1952), who observed a shortened survival-time, but they likewise could not demonstrate red cell auto antibodies or iso antibodies

The thrombocytopenia has been explained as a consumption of platelets in the formation of myriad thrombi but the commonly held view that the "thrombi" are composed of platelets perhaps merits critical reconsideration because, as we have shown, the "thrombi" have all the tinctorial qualities of fibrin Platelet agglutinins were not detected in the present case, as was also the experience of Bernheim (1943) and Adelson (1952) Adelson, however, found a shortened survival-time of transfused platelets and interpreted this as evidence of a destructive mechanism Possibly this mechanism may be the same as that of idiopathic thrombocytopenic purpura, and it seems difficult to understand why previous workers have felt it necessary to postulate that platelet thrombi are the cause of the thrombocytopenia in thrombotic micro-angiopathy

The episodic character of the clinical course is reflected in the microscopical finding of varied degrees of hyalinisation, organisation, and canalisation of the occluding masses, the appearances indeed suggest that the les had appeared in crops

Splenectomy has been done in a few cases with benefit Presumably, therefore, the spleen plays significant part in this disease Likewise administrat of cortisone or of corticotrophin, given in relatively sm doses, does not appear to influence the course of t disease

No lesions were noted in either skin or bone marr Bone-marrow aspiration has, however, yielded diagnost aid in the past (Cooper et al 1952)

The virtual lack of histological evidence of necros other tissue damage, despite the multiple peripher vascular thrombosis, makes it difficult to explain th curious lethal character of the disease In the pres case adrenal hæmorrhages were unusually severe, an this could well have contributed materially to the fat issue

This curious absence of necrosis rather suggest th the occlusions are confined to a level of the vascular tr where there is an anastomosing network, and it ma well be that, whatever the appearance of the involv vessel, it is always a precapillary arteriole An apparent widening of the vessels that contain thrombi was one o the most obvious features in sections from the pres case Indeed, the walls of some affected vessels were s attenuated that the usual distinction between venule an arteriole was lost Comparable dilations were noted b Orbison (1952), who showed, in reconstructions prepare from Meacham's two cases, that these were situated a the arteriolo-capillary junctions It is possibly significan that Humble (1949) found that the site of dermal bleedin in purpuric patients was the arteriolo capillary junction It therefore appears that damage is done at this particula point in the vascular tree, but it is not clear what relation if any, this anatomical localisation bears to the formatio of occlusive masses

The precise nature of the occlusive material is stil unknown Moschcowitz (1925) believed that it wa formed of agglutinated red cells, but this is no longe generally accepted, the common view being that it is a mass of agglutinated platelets (Lutz 1951) This view was apparently reached by a process of exclusion, since neither bacteria, nor red cells, nor threads of fibrin wer found in the so called thrombi It was next stated b Meacham et al (1951) that the thrombotic material ha the same staining reaction as platelets The pres investigation, though extending and confirming the results, if not their interpretation, shows that the throm botic material stains like fibrin The absence of fibrilla structure does not mean that the material is not fibri A compacted granular material giving the staining reac tions of fibrin is not uncommonly seen along with th fibrillar form in infective and exudative disease of th lung That both these forms are fibrin is very possib in the light of work by Ferry and Morrison (1947), wh showed that fibrinogen, clotted under different cond tions, may yield two distinct types of clot, one retic lated and fibrillar, and the other more homogeneous an compact A granular "clumped" form of fibrin wa described by Howell (1914) in mixtures of fibrinogen an thrombin, where the amount of the latter was insufficien to give a firm clot It is therefore probable that th conversion of fibrinogen to fibrin may give sever morphological variants of fibrin As Robb-Smith (195 points out, there is no a-priori justification for assumin that the mechanism of formation of fibrin is identic in each case

The observed differences in the properties of clo formed under various conditions presumably depend o the manner in which the fibrinogen molecules are link together during polymerisation It is conceivable th in the present disease the conversion of fibrinogen similar extraction with alkaline methanol activity remained in the cyclohexane From this we conclude that the active substance is an amine

Gas liquid chromatograms were run with Apiezon M ' at 197°C and nitrogen as carrier gas (James and Martin 1954) Both the original distillate and the basic fraction obtained from the distribution with acidified methanol proved to be highly complex, and the activity was confined to a zone of volatility roughly equivalent to that of a hydrocarbon containing 14 carbon atoms The recovery of activity from the gas chromatogram was, however, very low Further work at lower temperatures is indicated

Attempts to fractionate on liquid liquid columns between acidified 80% methanol and cyclohexane also did not lead to a striking increase in potency, and further work on these lines is also needed

The fractionation of the largest batch proceeded as follows

13 kg of ' vegetable lecithin " was hydrolysed with 7 25 kg of KOH and 18 litres of ethanol in a steam jacketed pan The KOH was first dissolved in the boiling ethanol and the lecithin added with stirring until fully dissolved The material was left for ninety minutes at 100°C, and much NH_3 and $(CH_3)_3N$ were given off Cold water was run into the jacket until it cooled to about 45°C and the material was then a pasty mass 8 litres of water was added, and the mass liquefied Ice was now added until 30 litres of water and 45 litres of ether had been used The material was well stirred and left to settle overnight, it separated into two layers The upper layer was siphoned off, and to it was added a third of its volume of water An ether layer was separated, and the aqueous layer was extracted with an equal volume of ether in a counter current extractor of about five theoretical plates' efficiency The material remaining in the vat was extracted with 30 litres of ether with simple stirring The ether extracts were combined, washed with a small volume of water, and distilled The residue contained water and alcohol and was collected in a 10 litre bottle, and to it were added 5 litres of ether and 2 litres of water The ether layer was separated and concentrated, and the process was repeated with 500 ml of water and 2 litres of ether The ether layer was evaporated to dryness, and the residue was a *brown oil*, semisolid below 70°C It was *dissolved in 1 5 litres of acetone* and set aside at –5°C The precipitate was filtered off, washed with 1 litre of cold acetone, and discarded The acetone mother liquor and washings were evaporated down and yielded 90 ml of dark brown oil, liquid at first at room temperature and setting overnight to a semisolid

This material was distilled in a molecular still at 100°C, and 22 ml of a pale yellow oil, whose colour deepened on standing, was obtained This was active at 0 3 µg The undistilled residue was inactive at 10 µg

The distillate had a strong smell, which was even stronger in the more volatile material that had collected in the cold trap

15 6 g of the distillate was distributed between 250 ml (80 20 1 by vol) of methanol water conc H_2SO_4, and 250 ml of cyclohexane The methanol layer was run off, and the cyclohexane layer re extracted with 250 ml of the acidified aqueous methanol The combined methanol extracts were made alkaline with NaOH, freed from methanol by distillation, and extracted thrice with ether On evaporation of the ether a dark-brown oil weighing 1 74 g remained This material, the ' basic fraction," was active at 0 03 µg per guineapig

The neutral fraction " from the cyclohexane was inactive at 0 3 µg

When the extraction procedure was repeated with NaOH in place of H_2SO_4, the cyclohexane and methanol fractions were both active at 0 3 µg

20 µl of the basic fraction was applied to a gas chromatogram 120 cm long with a stationary phase of apiezon M at 197°C The nitrogen pressure was 71 cm Hg Fractions were collected in cotton wool moistened with ethanol packed in tubes 12 cm long and 1 cm in diameter (Excess ethanol was first removed by suction on a water pump and the tube then attached to the exit tube of the apparatus with a sleeve of silicone rubber tubing)

Tubes were changed after (*a*) 7½, (*b*) 17½, (c) 27, (*d*) 37, and (c) 56 minutes

CONDITIONS IN WHICH DESENSITISATION DEVELOPED WITH THE AGENTS TESTED

Agent and dose per kg of body weight	Diet deficient in ascorbic acid	Reduced glutathione (150 mg per kg of body-weight)
Cortisone acetate * 5 mg (Long and Miles 1950)	–	–
Alloxan 25–50 mg (Long et al 1951)	–	–
Ethionine 50 mg (Long 1954b)	–	–
Cysteinamine 100 mg (Long 1954c)	–	–
Insulin 2 units compensating phase succeeding hypoglycaemia (Cornforth and Long 1953)	–	–
Dehydro ascorbic acid 50 mg (Long et al 1951)	–	–
Growth hormone 10 mg (Cornforth and Long 1953)	+	–
Glucose 1 phosphate 0 01 mg (Cornforth and Long 1952)	–	+
Lysergic acid diethylamide 0 00018 mg (Cornforth and Long 1952)	–	+
Polyoxyethylene ethers 10 mg (Hart et al 1952)	–	–
N acetylsphingosine 10 mg (Fisher et al 1951)	–	–
Peanut-oil factor 0 000006 mg (Long and Martin unpublished)	–	+

* For activity of related steroids see Long and Spensley (1954)

The tubes were washed out with 10 ml of ethanol, and 1 ml of this solution was considered equivalent to 2 mg of the basic fraction The fractions were tested at 0 5, 0 3, and 0 03 µg equivalent basic fraction Only (c) was active (the tests at 0 3 and 0 03 µg were with five guineapigs each and not fully satisfactory)

It was considered that activity was probably lost in this experiment

Eggs and Other Substances

20 hard boiled egg-yolks were extracted in a Waring Blendor with 2 portions of 500 ml of ether After filtration the ether was evaporated off 100 g of yellow oil was obtained In three weeks a bulky sludge precipitated this was centrifuged down The oil was active at 10 mg, the precipitate was doubtfully active at 10 mg

From 50 ml of oil 1 g of unsaponifiable matter was obtained by ether extraction after alkaline hydrolysis, it contained much cholesterol and was active at 20–200 µg

Linseed oil was active at 1 ml, and soybean lecithin was active at 10 mg, but olive oil, almond oil, and wheat germ oil were all inactive at 1 ml

The extracted egg yolk protein was dried and fed at 500 mg daily for three days and proved to be inactive

Comment

Sensitivity to tuberculin is clearly a complex phenomenon that can be influenced by various factors (see table) The diversity of substances that depress sensitivity is such that no single explanation will suffice Presumably those influenced by a diet deficient in ascorbic acid or by injection with reduced glutathione have some part of their mechanism of action in common Long (1955) discusses possible modes of action of several of these substances

Summary

The response to intradermal tuberculin was used as a measure of allergic hypersensitivity in albino guineapigs infected with B C G

Single subcutaneous injections of arachis oil depressed sensitivity slightly but significantly

Purification resulted in a non-toxic fraction that, in a dose of 0 000006 mg per kg of body-weight depressed sensitivity to a degree comparable with that obtained under similar conditions with cortisone acetate in a dose of 5 mg per kg of body-weight, which is maximally effective

RHESUS (D) FACTOR IN SARCOIDOSIS

LÉON CUDKOWICZ
M D Lond , M R C P
REGISTRAR, DEPARTMENT OF THORACIC MEDICINE,
ST THOMAS'S HOSPITAL, LONDON

I REPORT here the results of a brief investigation after the chance finding of a negative Rh (D) factor in a young patient with sarcoidosis

32 patients of this department who are suspected of having sarcoidosis had their blood group and Rh (D) factor determined , the accompanying table summarises the diagnostic features in favour of the diagnosis of sarcoidosis and the blood results Genotype examination in respect of c,C,e,E, and d could not be carried out, and the results are expressed in terms of rhesus (D) factor only

The sera were scrutinised for atypical antibodies, and direct Coombs tests were recorded on most samples

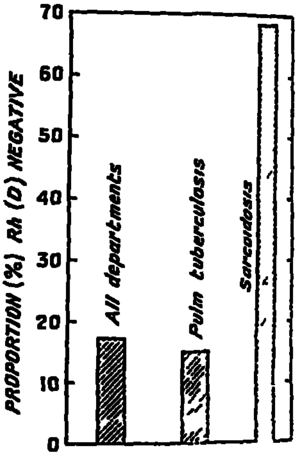
21 of the 32 patients suspected of having sarcoidosis were found to have Rh (D) negative blood, whereas the ABO blood-groups were fairly normally distributed In all the patients with Rh (D) negative blood radiography of the chest revealed pulmonary involvement On the other hand, of the 11 whose blood was Rh (D) positive, 4 (cases 5, 9, 20, and 29) showed no radiographic abnormality at the hila or in the lung fields and in 1 (case 11) there was doubtful enlargement of the left hilum only. In the remaining 6 the lung involvement was widespread, and in case 31 there were also unusual skin lesions

4 patients (cases 2, 4, 13, and 26) presented with ocular signs of sarcoidosis in addition to the lung changes, and their blood was Rh (D) negative A patient with Eale's disease (case 29), however, whose chest radiographs remain consistently normal, was Rh (D) positive Similarly case 31, who has widespread ocular, skin, and lung lesions, proved to be Rh (D) positive The diagnosis in this patient is still subjudice despite " sarcoid like" lesions in a skin biopsy

FINDINGS IN 32 CASES OF SARCOIDOSIS

Case no	Liver biopsy	Chest radiograph	Rh (D) factor	Blood group	Other biopsies
1	Pos	Mottling and hila +	Neg	A	
2		Mottling	Neg	A	Pos keloid biopsy
3	Pos	Mottling and hila +	Neg	A	
4	Pos	Hila +	Neg	B	
5		Normal	Pos	AB	Endometrial sarcoid
6	Neg	Mottling and hila +	Neg	A	
7	Neg	Hila +	Neg	O	
8	Pos	Mottling and hila +	Pos	A	Skin scar—sarcoid
9		Normal	Pos	A	Sarcoid of parotid
10	Neg	Mottling	Neg	B	
11		? lt hilum	Pos	O	Sarcoid in synovia
12	Pos	Mottling and hila +	Neg	O	
13	Pos	Hila +	Neg	A	
14	Pos	Hila +	Neg	A	
15		Hila +	Neg	O	
16	Neg	Mottling	Neg	O	
17	Doubtful	Hila +	Pos	O	
18	Pos	Mottling and hila +	Pos	O	
19		Mottling and hila +	Neg	O	
20		Normal	Pos	A	Sarcoid in muscle biopsy
21		Hila +	Pos	O	
22	Focal necrosis	Hila +	Neg	A	
23	Neg	Mottling	Pos	AB	
24		Hila +	Neg	O	
25		Mottling and hila +	Neg	O	
26		Hila +	Neg	B	
27		Hila +	Neg	O	
28		Mottling	Neg	O	
29		Normal	Pos	A	
30	Neg	Hila +	Neg	A	
31		Mottling	Pos	O	Sarcoid like skin lesions
32		Mottling	Neg	O	

4 patients (cases 5, 9, 11, and 20) in whom the principal manifestations of sarcoidosis originated outside the lungs had Rh (D) positive blood



Proportions of patients with Rh (D) negative blood (1) from all departments (1000 cases) , (2) with pulmonary tuberculosis (93 cases) , and (3) with sarcoidosis (32 cases)

In 5 Rh (D) negative patients sarcoidosis was confirmed by liver biopsy , and in each of 4 Rh (D) positive patients liver biopsy was also positive In 1 Rh (D) positive patient the biopsy of the liver was of doubtful value ; and in 1 (case 22), whose blood was Rh (D) negative, the liver showed focal necrosis 1 Rh (D) positive and 5 Rh (D) negative patients had negative liver biopsies

Rhesus Factor in Other Groups

Of 1000 patients of all departments of this hospital who had their blood-group and Rh (D) factor determined in the period September to November, 1955, 173—i e, 17 3%—were Rh (D) negative 93 patients with pulmonary tuberculosis who were known at one time to have had positive sputa showed a somewhat similar Rh (D) factor distribution , of these 93 patients, tested at this hospital or at the Lambeth and South Western Hospital, 14 (15 1%) were Rh (D) negative (see figure)

DISCUSSION

In the present series of cases of sarcoidosis the prevalence of hilar lymph-node and lung involvement was higher in patients with Rh (D) negative blood than in others Of the total of 32 patients 21—66%—were Rh (D) negative , this proportion is probably significantly greater than that in the general population, and suggests that Rh (D) negative patients react more commonly than Rh (D) positive patients with the production of sarcoidosis (see figure)

No conclusions can be drawn from these figures in respect of susceptibility to sarcoidosis among Rh (D) negative patients, and much larger series are required for any statistical analysis

I suggest that the examination of the Rh factor is of some additional help where sarcoidosis is suspected The fairly large proportion of Rh (D) negative patients observed in this inquiry compares with the positive Kveim's tests in 12 of the 16 cases of sarcoidosis recorded by James and Thomson (1955)

Summary

Of 32 patients suspected of having sarcoidosis 21 were found to have Rh (D) negative blood as well as radiographic evidence of hilar or lung involvement Of 11 whose blood was Rh (D) positive, 4 had normal chest radiographs

This small series suggests that Rh (D) negative blood is commoner in patients with sarcoidosis than in the general population

I thank Dr J H Anderson for permission to study these patients, who are under his care, and Dr J L Pinniger and his technical staff for the determinations of the blood groups and Rh factor of the patients with sarcoidosis

REFERENCE

James, G D Thomson, A D (1955) *Quart J Med* 24, 49

idence of diabetes insipidus her fluid intake being at first 419 ml. daily, later reduced to 887 ml. on account of lack of bsorption from the stomach

She developed a pyogenic intracranial infection from a enicillin resistant staphylococcus, and the spread of this nfection was responsible for death

Macroscopic Examination (P.M. 95 1951)

Necropsy revealed purulent pachy- and leptomeningitis The pituitary stalk was not found Surrounded by thick exudate, the floor of the third ventricle was replaced by an operative deficit leading into the cystic cavity of the tumour There was recent thrombosis of the superior longitudinal and right lateral sinuses The pituitary gland (0 6 g) was flattened n an expanded sella turcica

The right adrenal was swollen and destroyed by recent hæmorrhage, the left appeared normal

Microscopic Examination

Pituitary—There is patchy necrosis of about half of the parenchyma of the *anterior* lobe The necrotic areas are infiltrated in places with lymphocytes and plasma cells The residual parenchyma is poorly preserved, the cells being in stages of degeneration The basophils are pale, swollen, and agranular, the perinuclear cytoplasm appears stringy but at the periphery it is homogeneous and slightly hyaline In the acidophil cells the granules are often clumped

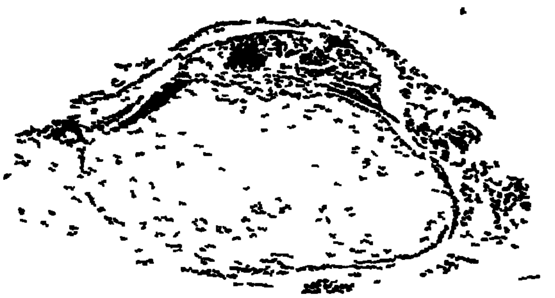


Fig 2 (case 3)—Horizontal section of pituitary as in fig I (H and E ×35)

Four large sinusoids near the centre of the anterior lobe are thrombosed, with early organisation of the thrombus The *posterior* lobe is normal

Other endocrine organs—The hæmorrhage in the right *adrenal* is associated with thrombosis of the central vein, the gland is infarcted The capsule is infiltrated with numerous leucocytes and two large groups of gram positive cocci occupy softened areas in the substance of the gland. The left adrenal contains abundant lipoid, two of the capsular veins are plugged with ante mortem thrombus, and the cortex shows focal hyperæmia The *thymus*, *spleen*, and *lymph nodes* are heavily depleted of small lymphocytes The *thyroid* is normal

Anterior-pituitary insufficiency was recognised in the postoperative course of both of these patients It is probable that, in case 2, life was prolonged by hormone therapy, but this masked the spread of pyogenic infection which, as the pathological examination showed eventually spread systemically with the promotion of thrombosis in the adrenal veins In 1933 hormone therapy was not available, and the postoperative picture in case I was that of unmitigated anterior lobe insufficiency These two cases therefore, agree with Cushing s early observation that division of the stalk can result in severe necrosis of the anterior lobe A brief note is now added on a third case in which, although anatomical division of the stalk was not inflicted, the pathological findings throw considerable light on the vascular pathways implicated in the production of this necrosis

THIRD CASE

A man aged 44 had complained of pain in the right upper limb for 4 months, and more recently of severe pain in the back and behind both eyes He was admitted to hospital in April 1939 in stupor His wife related that 5 days earlier, he had become hysterical and taken to his bed where he had since remained He deteriorated mentally and, though able to recognise his wife was dull and rambled in his speech He lost weight rapidly and became pale On the day before admission he was restless, feverish, and sweating and had visual hallucinations

On examination he was semicomatose, with eyes half closed and mumbling perpetually He occasionally attempted to answer questions His skin was sallow with yellowish-brown pigmentation of the face There were sordes on the lips and his tongue was dry and furred Enlarged supraclavicular glands, and radiographic evidence of tumour deposits in the pelvis and vertebræ were found, but the primary source of these was not determined Blood pressure 100/50 mm and 103·65 mm 4 days later *Nervous system* neck-rigidity present, no papillœdema, right external rectus palsy and nystagmus Blood examination showed a leuco-erythroblastic anæmia Lumbar puncture yielded faintly yellow cerebrospinal fluid mixed with blood at a pressure of 170 mm, containing 20 lymphocytes per ml Urine cloud of albumin Blood urea 0 055 g per 100 ml

No disturbance of water balance was noted but records of intake and output were not kept He became increasingly drowsy, and resentful of attention Urinary incontinence developed and he died, with signs of pneumonia 6 days after admission

Macroscopic Examination (P.M. 164 1939)

Primary carcinoma of the pylorus was found, with extensive carcinomatosis of the lymph nodes and skeleton including the skull There was pachymeningitis carcinomatosa of the left parietal region and over the base with recent thrombosis of the cavernous sinuses The brain and pituitary stalk appeared unaltered, but the anterior lobe of the pituitary (1 2 g) was pale and opaque The adrenals (10 4 g), testes (25 6 g), and thyroid (36 5 g) appeared normal except for a partly calcified adenoma in the thyroid

Microscopic Examination

Pituitary—The appearances of the *anterior* lobe closely resemble those of case 1 and the age of the lesion as judged by the peripheral granulation tissue, is similar (fig 2) The capsule is thickened by recent hæmorrhage and chronic inflammatory cellular exudate, while many of the small veins are permeated with carcinoma The *posterior* lobe is infiltrated at its margin by a few groups of tumour cells, associated with areas of hæmorrhage and some inflammatory cellular infiltration

In coronal sections through the hypothalamus and pituitary stalk there are small areas of recent hæmorrhage in the tuber cinereum and in the stalk In the latter there are also areas of necrosis and many of the portal vessels are plugged with carcinoma cells and thrombus (fig 3) This involvement of the portal vessels extends throughout the length of the stalk to its level of attachment with the gland Branches of the superior hypophyseal arteries over the surface of the stalk are normal and patent

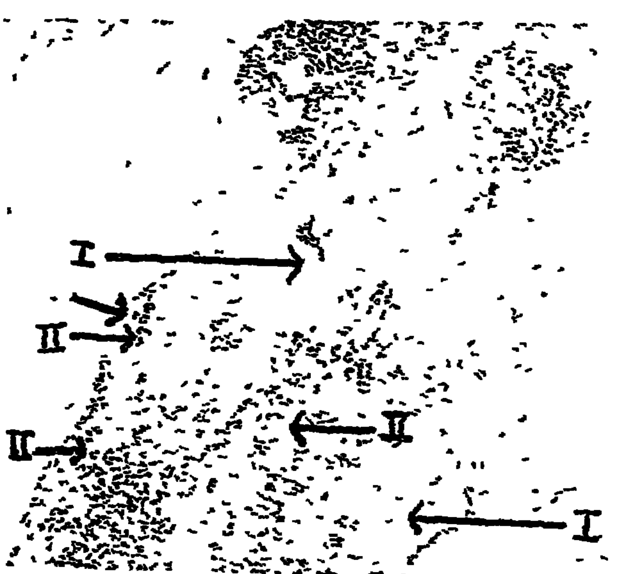

Fig 3 (case 3)—Upper part of pituitary stalk showing areas of hæmorrhage necroses (I), and plugging of portal vessels (II) (H and E. ×21) myelitis infects an individual in a family, nearly all of his susceptible household associates are concurrently infected It may well be that the antibody patterns found in the children in this survey are reflected at least in the older members of their families This seems likely from the epidemiology of poliomyelitis in Northern Ireland

The total numbers of confirmed paralytic cases in the boroughs and counties of Northern Ireland in 1950–55 are as follows

	1950	*1951*	*1952*	*1953*	*1954*	*1955*	*Total*
Belfast borough	110	15	19	31	14	1	190
Londonderry borough	0	0	1	34	4	0	39
Co Antrim	46	18	22	51	11	5	153

TABLE II—ANTIBODY IN SIBLINGS

	Pairs of siblings		
Tested	With similar antibody pattern to all three types	With one additional type of antibody in older child	With on additional ty of antibody younger ch
29*	18	10	1

* Includes 3 siblings in one family

The highest paralysis rates were in the 0–4 year a group. Indeed of 669 confirmed paralytic cases in 1950-5 311 (46 5%) occurred in children aged less than 5 yea The small number of cases in older age groups sugg that they are relatively immune Unfortunately th were insufficient samples in the 5–9-year age group for to examine any possible relationship between antib and paralysis-rates If it is assumed that the samp tested from children aged less than 5 years were rep sentative of the recent poliomyelitis experience of t age group in Northern Ireland, some relationship mig be found between the antibody rate of the 0–4 ye age group and the incidence of paralysis in this a group in recent years That some such relationship m exist (in spite of the selected nature of the samples) seen from table III

Although the data for the 0–4-year age group in table do not merit statistical analysis, places with h paralysis-rates in the 0–4 year age group seem to ha high antibody rates in that age group, and low paraly rates seem to be associated with low antibody rat This apparent association is most noticeable in compar the paralysis-rates in table III with the proportion children with antibody to type 1 poliovirus

Of the thirty-four strains of poliovirus recovered Northern Ireland since August, 1955, twenty nine w type 1, and twenty six of these were from paralytic ca (Type 2 was isolated from 2 paralytic cases, and t other three strains—two of type 3 and one of type 2 were from non-paralytic cases) Furthermore the t strains of poliovirus isolated (at the Central Public Heal Laboratory, Colindale) from paralytic cases fr Northern Ireland in 1953 were also of type 1 All th

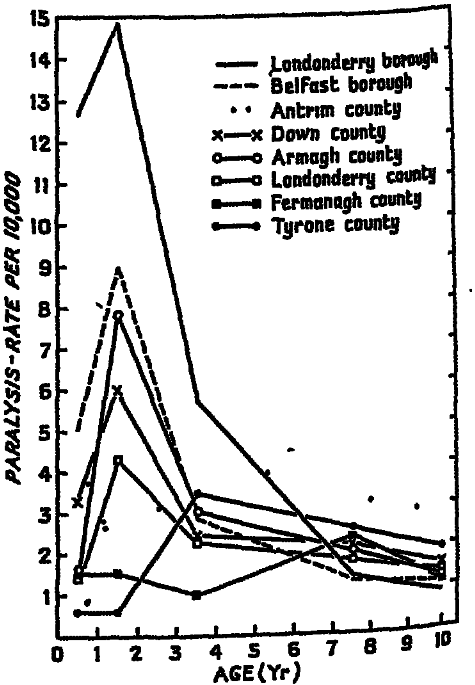

Fig 3—Annual age-specific paralysis-rate in 1950-55

---

† There were 25 notified cases from co Londonderry in which no information was available about the presence or absence of paralysis A proportion of these patients may have had paralysis, and the paralysis rate for co Londonderry may therefore be slightly higher

REVIVAL OF STORED BLOOD WITH GUANOSINE

AND ITS SUCCESSFUL TRANSFUSION

T A J PRANKERD
M.D Lond , M R C.P
ASSISTANT, MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

IN earlier papers (Prankerd and Altman 1954a and b) attention was drawn to the apparent benefit of two nucleosides, adenosine and guanosine, to red-cell metabolism during incubation of blood in vitro at 37°C In these experiments it was observed that, after twenty-four hours' incubation, red-cell metabolism continued in the presence of these nucleosides whereas it ceased if glucose alone was present This effect of these nucleosides was ascribed to their providing, after cleavage by cell enzymes, ribose phosphate; which could be utilised by the red cell for glycolysis, apparently when glucose could no longer be utilised

About the same time Finch and Gabrio (1954) briefly reported that adenosine improved the post-transfusion survival of stored blood, and they have since (Gabrio et al 1955) reported their observations in more detail Blood was stored, by these workers, with adenosine at 4°C and incubated at various times during its storage at 37°C, finally, the cells were labelled with ^{51}Cr, washed with saline solution, and transfused into healthy recipients Estimated cell survival showed great improvement with this treatment Adenosine, however, is very toxic when injected into man (Wedd 1931, Drury 1936) and it would prove unsuitable for adding routinely to stored blood unless the cells were washed before administration

I report here further observations on survival of blood stored in standard acid-citrate-dextrose preservative (A-C-D) at 4°C for periods up to eight weeks, and revived before transfusion with one of the two nucleosides Of these two compounds guanosine has been shown to be pharmacologically inactive, and blood revived with it has been transfused to man in routine manner without undesirable effects It should therefore prove to be a practical and simple means of increasing the optimal storage time of blood and eliminating waste

Methods

Blood collected in A-C D by the North London Blood Transfusion Service was used in these experiments after it had been discarded by the blood-bank as no longer serviceable This usually happens after three weeks' storage at 4°C

Two procedures were used to revive the cells

(i) At various times after three weeks storage 5 µmols of adenosine or of guanosine, in sterile isotonic saline solution, was added for each millilitre of stored blood, and 25 ml of the mixture was incubated for an hour at 37°C At the same time a further 25 ml of the same blood was incubated separately without the nucleoside

(ii) The nucleoside was added to blood in the same concentration at the end of three weeks' storage, and the mixture was incubated at 37°C for an hour and subsequently stored again at 4°C until required for transfusion The blood was then reincubated for an hour before transfusion

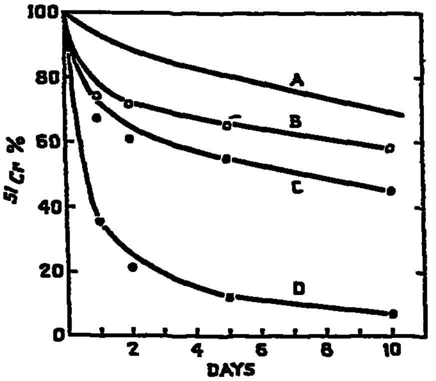

Fig 1—Survival curves for blood stored for six weeks in A C-D and revived immediately before transfusion A, fresh blood transfusion (mean of 5 normals) , B, 6-week stored blood incubated with adenosine C 6-week stored blood incubated with guanosine D, 6-week stored blood incubated with glucose

To estimate post-transfusion survival 30 µC of $Na_2{}^{51}CrO_4$ (15 µC per µg Cr) were added to 10 ml of revived blood and allowed to stand for an hour The blood was then centrifuged for ten minutes at 500 g and the supernatant plasma was removed The remaining cells were washed once with 20 ml of sterile saline solution, and recentrifuged the supernatant fluid was again removed, and the cells were finally suspended in 5 ml of saline solution and injected into a healthy recipient Samples of blood were taken at the end of ten minutes, twenty-four hours, forty-eight hours, about four days, and about ten days after injection, and the radioactivity in 10 ml. of these samples was estimated with an Ekco "pillar-type" scintillation counter The survival of cells was computed by standard methods taking the ten-minute sample as the 100% value The survival values at forty-eight hours were then expressed as per cent survival compared with freshly transfused cells

TABLE I—SURVIVAL AND CONTENT OF ADENOSINE TRIPHOSPHATE OF CELLS STORED FOR VARIOUS PERIODS AND INCUBATED WITH NUCLEOSIDES IMMEDIATELY BEFORE TRANSFUSION

Storage (days)	Nucleoside	% survival at 48 hr		Adenosine triphosphate (µg of phosphorus per ml of cells)		
				Before incubation	After incubation	
		Nucleoside	Glucose		Nucleoside	Glucose
38	Guanosine	75	54	25	41	30
	Adenosine	79	28	21	54	10
42	Guanosine	69	28	21	27	
	Adenosine	51	10	16	36	0
56	Guanosine	49	10	16	29	

To assess the relative toxicity of the two nucleosides, solutions of graded strength were injected into a narcotised cat, whose blood-pressure and electrocardiograms were continuously recorded

As a check on cell metabolism, samples of red cells were analysed chromatographically for phosphate esters as described previously (Prankerd and Altman 1954b) before and after revival with nucleoside

In a final experiment a pint of six-week-old blood, restored with the same quantity of guanosine (750 mg per 540 ml blood) in the manner described, was transfused to a recipient whose pulse, blood-pressure, electrocardiograms, temperature, hæmoglobin, blood-urea serum-bilirubin, and urinary urobilinogen were frequently recorded

Results

Fig 1 shows the survival after transfusion of labelled cells stored in A-C-D for six weeks and reincubated with one of the two nucleosides, or glucose alone before administration The increased survival of the nucleoside-treated cells at the end of forty-eight hours is obvious, and thereafter they survive normally

Table I summarises survival experiments on revived blood after various periods of storage and compares their survival with control samples The amounts of adenosine triphosphate in these cells before and after incubation are also shown Incubation with either of the two nucleosides persistently improves cell survival and is associated with resynthesis of intracellular adenosine triphosphate, which does not happen with glucose alone there was also intermittent diarrhœa The patient died on Nov 20, 1954, sixty days after admission to hospital

Necropsy Findings

The main findings 61 hours after death were those of congestive heart failure Several small recent infarcts were present in the right lung The heart was hypertrophied (22oz), mainly on the right side, its muscles and valves showed no lesion, and the coronary vessels were patent

Histology confirmed the macroscopic findings In an extensive search, including examination of more than a hundred sections of the heart, no toxoplasma was found Scattered throughout the heart muscle were a few foci of lymphocytes, plasma cells, and mononuclear cells, occasionally forming a perivascular cuff, or adjacent to vessels in the interstitial wall These were mainly in the left ventricle

Isolation of toxoplasma —A portion of heart muscle was forwarded to Dr Cathie at the Hospital for Sick Children, London, and toxoplasma was isolated by animal inoculation (Cathie 1955)

Discussion

Post mortem diagnosis of toxoplasmosis is difficult in the absence of animal inoculation because the toxoplasma may be very scanty and there are no specific histological stains

The degree of cardiac myohypertrophy was striking and, in the absence of other causes, must have been due to primary myocarditis Although scanty, it appears significant that histological lesions were found, particularly in the left ventricle

Paulley et al (1954) have pointed out that toxoplasmosis should be excluded in all obscure forms of myocarditis

Adams et al (1953) describe the changes in muscle as a focal disseminated myositis We were impressed with the scantiness of such lesions in the heart muscle in the present case, despite the well-marked clinical findings

Callahan et al (1946) pointed out two distinct forms of toxoplasmosis in the adult one they described as an acute exanthema with the most pronounced lesions in the lungs, and the other is a chronic asymptomatic disease, seen in mothers of infected children and revealed by the presence of neutralising antibodies in the blood Our case resembles Callahan's first type, except that the mode of death was cardiac

The effect of treatment is difficult to assess because the number of cases diagnosed appears to be small The various antibiotics, a sulpha drug, and pyrimethamine were all without effect in the present case

In some of the adult cases the infection has been acquired in a laboratory (Beverley et al 1955) In other cases the possibility of vectors—e g, ticks and mites—has been considered Toxoplasmosis is known to be widespread in the animal kingdom, with varying clinical manifestations

It appears relevant in the present case that, before the patient's illness, his dog was taken ill with diarrhœa and vomiting, was ill for six weeks, and died in July, 1954 A veterinary surgeon had advised destruction of the dog, but the owner had refused Olafson and Monlux (1942) found that, in dogs, toxoplasmosis produced granulomatous lesions in the intestines, lymph nodes, liver, and lungs, with *minimal* involvement of the nervous system, and there may be acute enterocolitis with focal ulceration of the mucosa Possibly the infection in the present case was acquired from the dog

Summary

A case of acute myocardial toxoplasmosis from which the organism was isolated is described

It is suggested that the source of infection in this case was from a dog

We wish to acknowledge the very considerable help and advice of Dr R Blowers of the Public Health Laboratory, Middlesbrough, and Dr I A B Cathie, of the Hospital for Sick Children, London

Preliminary Communication

HYDROCORTISONE IN THE PREVENTION OF TRANSFUSION THROMBOPHLEBITIS

THROMBOPHLEBITIS is a common troublesome complication of intravenous infusions,[1] especially when they are protracted or when hypertonic solutions are given[2] To avoid it Bolton Carter suggested[3] that no infusion should be continued longer than eight hours When it is essential to provide nutriment parenterally for several days—e g, in anuria and in hepatic coma—the use of fat emulsions, the catheterisation of the great veins, and the insertion of a cannula into the cephalic vein have been recommended

It was observed that patients receiving systemically large doses of cortisone or of hydrocortisone seemed less liable than others to develop phlebitis after protracted infusions—an effect which was attributed to the ability of these hormones to suppress inflammation Therefore, when hydrocortisone alcohol became available, it was decided to test the power of this steroid, added to an intravenous infusion, to prevent or to suppress phlebitis, advantage being taken of the fact that a very high local concentration of hydrocortisone could be produced in the vein receiving the infusion by a dose which would be without systemic effect Three patients were selected in whom there was an indication for the intravenous administration of hypertonic dextrose, and they were given 20% dextrose solution containing 0 001% (10 mg per litre) of hydrocortisone

The three patients, all of whom were in hepatic coma were given infusions through standard red rubber tubing into peripheral veins The infusions were continued for 32, 46¹/₂, and 63¹/₂ hours and discontinued 2 hours, 6 days, and 12 hours before death The fluids given to the first patient included 2 litres of the 20% dextrose hydrocortisone solution, the two other patients received 3 litres each In the third patient the solution was not begun until the fastest rate of flow obtainable had gradually fallen to 11 drops a minute and the vein was indurated for three inches proximal to the site of puncture, after 6 hours the rate had risen to 60 drops a minute, and after 12 hours no induration could be felt

No clinical evidence of thrombophlebitis developed in any of these patients during or after the 20% dextrose hydrocortisone infusions, and at necropsy Dr W G Spector found no abnormality in the peripheral vein either macroscopically or microscopically The first patient had a recent ante mortem thrombus in the portal vein

None of these infusions was very protracted, the longest lasting 63¹/₂ hours In each case, however, 20% dextrose was given into a peripheral vein without causing thrombophlebitis In one case signs of thrombophlebitis disappeared while the solution was being administered It seems likely that the addition of 0 001% hydrocortisone was responsible for the tolerance shown by the

ested in cats and found to be similarly non toxic hese would probably be active in reviving stored red ells, but, since guanosine is the cheapest of this group f substances, it is thought to be of most practical mportance

Further work is in progress to ascertain the practical value of reviving stored blood by these methods and to assess factors which influence cell revival, but, in view of the lack of complications observed here after transfusion to man, the value of these methods may well be considerable

Summary

Observations have been made on the effects of the nucleosides adenosine and guanosine in reviving stored blood

Using blood which has been stored in A-C D for periods up to eight weeks good survival-times of transfused red cells can be obtained

The ability of cells to survive after revival is related to their content of adenosine triphosphate

Unlike adenosine, guanosine is not toxic to man, and whole blood revived with guanosine has been successfully transfused

I am grateful to Dr R Moulton and Mr D Willoughby for performing the experiments on cats

DIAGNOSIS OF SEX BEFORE BIRTH

C J DEWHURST
M B Manc, F R C S E, M R C O G
SENIOR LECTURER IN OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF SHEFFIELD

> " Another test for a woman who will bear or a woman that will not bear Wheat and spelt Let the woman water them daily with her urine If they both grow she will bear if the wheat grows it will be a boy if the spelt grows it will be a girl If neither grows she will not bear —*Egyptian Papyrus*

PROBABLY the commonest speculation on the outcome of any pregnancy concerns whether the baby will be a boy or a girl Many have professed their ability to foretell this by various criteria—e g, whether the baby is carried "all at the back" or "all at the front," whether a needle suspended over the abdomen rotates clockwise or widdershins, and when, in the menstrual cycle, the child is supposed to have been conceived More scientific methods have been based on the fœtal heart rate and the saliva test None of them, however, has stood the test of time and at present there is no alternative but to wait and see

The discovery, however, that genetic sex can be recognised by the different arrangement of chromatin according to sex in the nuclei in a biopsy specimen of skin (Moore et al 1953), an oral smear (Moore and Barr 1955), and a vaginal smear (Carpentier et al 1955) has suggested that the sex of a fœtus in utero might be diagnosed by examining the chromatin in the nuclei of desquamated skin cells in liquor amnii I report here the results of a short investigation of this matter

Principle

The nuclei of epidermal cells and other tissues of females contain a mass of chromatin which is rarely observed in male nuclei This aggregation of chromatin in female nuclei is located in different parts of the nucleus but is most definite and easiest to distinguish at the periphery, where Moore and Barr (1955) observed it in 40–60% of suitable nuclei in oral smears Most characteristically the chromatin is roughly triangular, with its apex towards the centre of the nucleus, but other shapes are found In male nuclei the chromatin is distributed in small particles throughout the nucleus and only rarely in aggregations Thus, with good nuclear detail, the sex can readily be distinguished

Technique

Liquor amnii was obtained by artificial rupture of the membranes for the induction of labour, or by paracentesis uteri, or at cæsarean section About 5 ml was centrifuged, and the supernatant fluid was poured away A thin smear, on a slide previously coated with egg albumin, was at once fixed in Papanicolaou fixative (equal parts of 95% ethyl alcohol and ether)

When liquor amnii obtained by paracentesis was prepared in this manner it was often washed off the slide during the subsequent staining, possibly owing to its low protein content This difficulty was partly overcome by adding 30% bovine albumin 0 25 ml to every 5 ml of liquor before centrifuging

The period of fixation was not critical and lasted 2–48 hours After fixation the slide was stained by a method similar to that described by Moore and Barr (1955)

The fixed smears were passed through absolute alcohol and 95% alcohol, two changes of about 2 minutes in each, then through distilled water for 5 minutes The smears were next stained with 1% fast cresyl violet for 10–15 minutes, differentiated in 95% alcohol (two changes) for about 1 minute and then absolute alcohol (two changes) for 1 minute, cleared in two changes of xylene, and mounted

Observations

Examination of the liquor amnii, obtained by artificial rupture of the membranes and prepared in this manner, soon showed that the typical arrangement of sex chromatin in female nuclei could be distinguished here as in other tissues Although many nuclei were found to be pyknotic and densely staining, and therefore unsuitable for study, as were others which were degenerate or distorted, a sufficient number were seen in which the nuclear detail was clear, to allow careful examination for sex differences In specimens from cases where females were subsequently born the female sex chromatin showed the typical arrangement described above in 25–40% of the nuclei suitable for study In specimens from cases where males were subsequently born less than 5% showed such an arrangement

Experiment I

In view of these differences, which were observed and confirmed in the earlier specimens examined, it was decided to test the accuracy of the method on liquor amnii obtained at cæsarean section or by artificial rupture of the membranes in cases where induction of labour was necessary 20 specimens were therefore examined which had been taken between the 36th and 42nd weeks of gestation, with one exception which was obtained at the 26th week from a severe case of pre-eclamptic toxæmia

Results—In 18 cases (10 male and 8 female) the sex of the fœtus was predicted correctly, and in 2 cases suitable nuclei were too few to permit any forecast These results seemed to indicate that, with care, a correct forecast of the sex of the fœtus is possible by this method, at least in so far as the sexing of nuclei in the liquor amnii is concerned

To test this hypothesis further and in circumstances more nearly resembling those in which it might be applicable, the study was extended to include liquor amnii obtained by abdominal paracentesis

In accordance with the changed policy of treating patients, most of the aggression was dealt with by social means (most commonly by removing the patient from the situation) rather than by physical methods of treatment Results suggested that a ward of chronically disturbed patients could be run without extensive use of sedation, E C T, or seclusion, if the frustrations and provocations leading to aggression were avoided by more individualised attention to patients The most important factors seemed to be the development of appropriate attitudes by nursing staff

Dr R K **Freudenberg** gave an account of an investigation conducted with Mr J P S Robertson into personal stresses in relation to psychiatric illness, the aim of which was to establish whether there are in fact statistically significant differences in the incidence of stresses in patients suffering from psychiatric illness as compared with a normal control group of non-psychiatric patients, and whether these influence diagnostic status and prognosis Only tentative conclusions were possible

100 consecutive psychiatric and 50 non-psychiatric admissions below the age of 60 were investigated according to a check-list of personal stresses covering ninety-one items grouped into questions on earliest childhood, childhood in general, school, occupation, sexual and marital life, and miscellaneous adult stresses 23 psychiatric patients were diagnosed as psychoneurotics, 19 as depressives, and 51 as schizophrenics

The incidence of personal stresses was highest in schizophrenics, while depressives did not differ significantly from controls, patients classed as psychoneurotic occupied an intermediary position but did not differ significantly from either of the other two groups Stresses found significant were present largely in the "childhood in general" section In schizophrenics there was a significantly higher incidence of discord between parents without actual separation, and objective occupational factors were more frequently frustrating Within the psychiatric group different stresses did not seem to be the main determinants for differences in diagnostic status Only the stresses of "childhood in general" had a suggestive differentiating influence on treatment response Abnormal birth or being an only child or an only child of that sex were more frequent in schizophrenics than in depressives, while orphans not brought up by parents were more frequent among psychoneurotics None of the separate stresses under occupation, sexual and marital, or miscellaneous adult stresses were of any significance Left handedness and late onset of voice change and menarche were commoner in schizophrenics who did not improve

In general, negative findings were more numerous than positive Among personal stresses in the three diagnostic groups of psychiatric patients in which there were no significant differences were some which had been frequently emphasised, including bottle feeding, weaning difficulties, lax or strict toilet training, over affection from the mother, early death of one parent, and early separation from the mother

Personal stresses in 100 consecutive female admissions over the age of 60 diagnosed as having senile dementia, arteriosclerotic dementia, paraphrenia, confusional states, or affective psychoses were compared with personal stresses in a control group of non-psychiatric patients over 60 The psychiatric group showed more frequent total stresses, among which were deterioration in financial situation, lack of occupation, and social isolation Senile dements had a distinctly lower incidence of stresses than patients with confusional states, the incidence approximating more closely to that in the control group The arteriosclerotic group showed most significant differentiating stresses Among patients with affective disorders, stresses concerned with domestic problems were probably the most important factors in prognosis

The results indicated that differences in diagnostic status were not due mainly to different personal stresses, although these might be slightly more important determinants than in the younger psychiatric sample

Dr Freudenberg felt that these findings were in agreement with the evolutionary theory of disease according to which illness is inherent in the nature of life itself and arises either from the universal preying of one species on another or from genetic variability or from environmental circumstances which the organism's inherited structure is unable to resist The complex relation of personal stress to illness could be further elucidated either by more refined methods which would yield more detailed and systematic knowledge of the existing social context and the particular person involved

New Inventions

INFLATABLE POSTNASAL TAMPON

FOR CONTROL OF INACCESSIBLE HÆMORRHAGE

When bleeding from inaccessible regions of the nose or from the nasopharynx continues despite every encouragement to natural arrest, the choice lies between inserting some kind of tampon and more drastic intervention under anæsthesia When the latter course involves a second anæsthetic, as in reactionary hæmorrhage following adenoidectomy, the decision is serious; for, in addition to the risk of anæsthetic depression in an exsanguinated child, there is the grave hazard of blood inhalation during induction The alternative, often preferred, of inserting a postnasal pack via the mouth is most uncomfortable and disagreeable for the patient, and the pack, unless placed with skill and precision, cannot be relied on to be effective It is also not without danger in that downward displacement can cause acute respiratory obstruction

A similar problem arises in those 10% of epistaxes which arise, usually in the elderly, from invisible areas of the nasal passages and which are unamenable to arrest by direct pressure Control may be effected by nasal tampon, but it is generally effected by occluding the exit of blood via the posterior and anterior choanæ—in other words, by *indirect* pressure

Since nasal hæmorrhage can be arrested indirectly by preventing egress of blood from the nasal cavities, further means were sought to apply this principle without resource to general anæsthesia or undue discomfort to the patient The shape of the postnasal space seemed to lend itself to the use of an inflatable balloon, which could theoretically apply direct pressure to any bleeding point there, and at the same time block the posterior choanæ and palatal hiatus, while with the addition of a nose clip the nasal passages would be effectively isolated

With the helpful cooperation of Messrs Down Bros and Mayer & Phelps Ltd what is believed to be a new instrument has been devised, and has now been used successfully to control postadenoidectomy hæmorrhage in 11 consecutive cases during the past eighteen months With the confidence gained in the earlier cases the instrument has latterly been used at a stage in the bleeding when hope for natural arrest had not been abandoned but continued loss of blood was regarded as

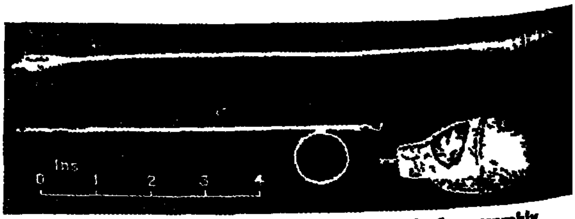

Fig 1—Balloon introducer, and bulb ready for assembly

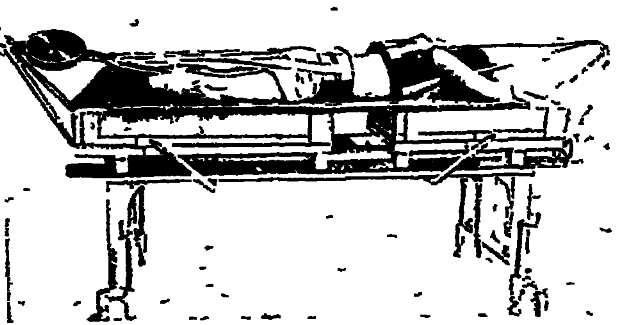

Fig 2—Traction has now been applied by turning wheel at head of couch platforms have separated, and spring balance registers 70 lb pull

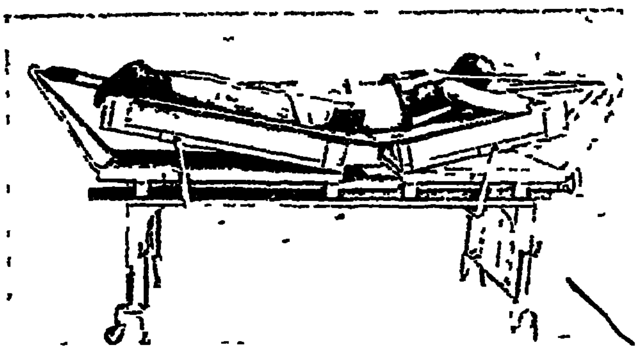

Fig 3—Ends of sections raised to cause hyperextension with traction still operating

Traction Couch

In the traction couch illustrated here (fig 1) the upper surface is divided into two sections, one for carrying the thorax, and the other for carrying the pelvis and the legs These can be raised at either end to elevate that end of the patient lying prone This enables variable and controlled hyperextension of the lumbar region to be obtained while traction is still being applied

The immediate application of a plastic support for the lumbar region while the patient is still lying on the couch is a safeguard against recurrence In doing this one can separate the two sections of the couch to create a gap which enables the plastic support to be wrapped round the patient and bandaged in position without removing the patient from the traction couch It is usual to apply this support without any hyperextension and with hardly any traction

The traction couch (figs 1–4) was originally made up for me from an old Bell's orthopædic table and is very satisfactory and easy to work The section carrying the pelvis and lower extremities is 41 inches long, and that carrying the head, neck, trunk, and arms is 29 inches long The two sections are mounted on runners and coupled together by a long coarse screw which causes them to separate from one another on rotation of the wheel at one end of the couch At both ends of the couch are stout brackets to which the harness is attached, one of these incorporating a spring balance The harness is made up of two belts of soft leather lined with 'Sorbo' rubber, the pelvic belt being 5½ inches wide and the one for the thorax 9 inches wide Adjustable webbing straps connect these belts to the brackets at either end of the couch

Lately I have used a specially designed table (fig 5) instead of that made up from a Bell's orthopædic table

Manipulation

The patient lies prone on the couch (fig 1), the harness is attached to the pelvis and thorax and the slack on the adjustable webbing belt taken up, and the wheel is turned causing the sections to separate until a pull of about 90–100 lb is registered (fig 2) Usually this pull immediately relieves the patient of pain After it has been maintained for 10–15 minutes, the ends of the couch are raised to produce hyperextension (fig 3) *Finally the couch is made horizontal again and the* traction discontinued

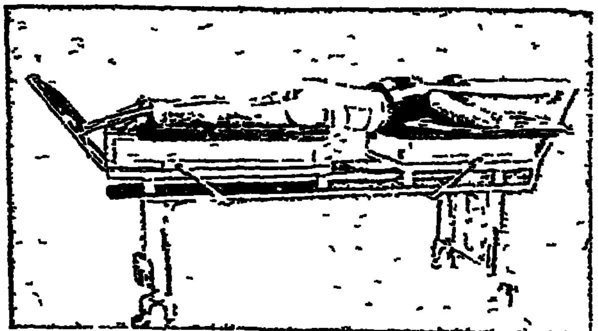

Fig 4—Application of plastic support for lumbar region with patient still prone with sections of couch separated

If at this stage it is considered advisable to make a plastic support, the patient remains prone on the couch with the thoracic harness in position, but ankle straps are *substituted for the pelvic harness* (fig 4) The sections of the couch are separated about 12 inches, and only just enough traction is applied to steady the patient and to prevent him from feeling uncomfortable because of the gap in front of his abdomen The whole of his lumbar region is now free for the plastic corset to be applied and moulded to him by bandaging

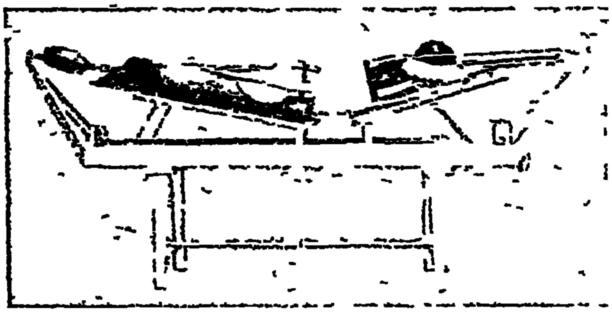

Fig 5—Specially designed couch ends of sections raised to cause hyperextension with traction still operating

Assessment of Effects of Traction-manipulation

The assessment of the results of any form of treatment of disc lesions in the lumbar spine is particularly difficult because of the large number of extremely variable features

Minor degrees of pain in the back and the leg are extremely common, they were formerly labelled lumbago or, sciatica, and few people of middle age have not experienced attacks of low back pain at some time or other There is a strong tendency to spontaneous cure, sometimes quite rapid, but a definite liability to recurrence The 50 patients reviewed here were in very severe and completely disabling pain, and required morphine to relieve them These patients have therefore been selected to some extent because the main symptom (pain) had been very severe Patients with less severe symptoms usually have a plaster or plastic support applied direct, and patients with minor symptoms are prescribed rest and physiotherapy

Results

The results are analysed in table I

Complete immediate relief of pain was obtained in 11 cases (22%), in 5 of these the pain returned to a slight the dissemination of *T saginata* eggs from sewage plants, for this probably explains the sporadic cases in Britain on farms where there is no evidence of a human carrier

The book will be useful to the human and veterinary pathologist and veterinary practitioner, but it is perhaps a little too detailed for the veterinary student There are many excellent illustrations and a comprehensive bibliography

Gynecology

Surgical Techniques Robert J Lowrie, m d , f a c s , associate clinical professor of obstetrics and gynecology, College of Medicine, New York University Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 523 £6 7*s* 6*d*

The companion volume to *Gynecology Diseases and Minor Surgery* is a massive book in which 60 contributors have written something for everyone—the undergraduate, the general practitioner, the postgraduate student, the obstetrician, and the general surgeon

The various surgical methods get full consideration for example, the authors give six different methods for the correction of stress urinary incontinence, four for urinary fistulas, and eight for hysterectomy

The book contains an enormous amount of information, nearly all of which is concerned with the practice of gynæcology in the United States, and in consequence many will think it of limited value to specialists and would be specialists in this country

For all the wisdom in its pages this is the kind of book that overwhelms by its complexity and by the very fact that it offers something for every reader As every contributor is an expert in his subject, then Rudyard Kipling must have been right "there are nine and sixty ways of constructing tribal lays, and—every—single—one—of—them—is—right!"

Modern Trends in Orthopædics

2nd series Editor Sir Harry Platt, m d , m s , f r c s , emeritus professor of orthopædic surgery, University of Manchester London Butterworth Pp 331 65*s*

In this first-rate collection of papers by experts, current views on a number of important conditions are summarised and analysed The writers give their considered opinions on what is sound and unsound in current practice There are chapters on reconstructive surgery, congenital dislocation, and fractures of the hip, traumatic and Pott's paraplegia, peripheral nerve injuries, antibiotics in bone and joint tuberculosis, muscle and tendon transplants in poliomyelitis, internal derangement of the knee, displacement of the upper femoral epiphysis, and contractures of the hand All are good, most of them excellent, and several brilliant Even the most accomplished orthopædic surgeon will gain from a study of these pages

L'art psychopathologique

Robert Volmat, chef de clinique à la Faculté de Médecine de Paris Paris Presses Universitaires de France 1956 Pp 325 Fr 1800

While the first world congress of psychiatry was meeting in Paris in 1950 an international exhibition of psychopathological art was held at the celebrated mental hospital of St Anne more than 2000 paintings by mental patients from 45 different institutions were on view In this book Dr Volmat commemorates that exhibition in a detailed manner suggestive of Germanic scholarship rather than French *esprit* His bibliography of 825 titles will be invaluable to students, but the text which precedes it is not easy reading

The first 135 pages set out the notes—translated, where necessary, but scrupulously unedited—which accompanied some hundreds of the pictures lent for this exhibition There follow three essays, on æsthetic form, on symbols, and on the expression of "archaic thinking" in art These open promisingly with a quotation from Malraux, to the effect that the psychotic, like the child artist, "à la maîtrise substitue le miracle"—a phrase which captures perfectly the unexpected quality of paintings by children and by schizophrenics But Dr Volmat's discussion of æsthetic philosophy is uninspiri Later he quotes Malraux again, to emphasise the paradox t in this age, when mass reproductions have made the beau of art generally accessible, the modern artist is more th ever repudiated In explanation, he advances Wittma view that modern art inflicts a narcissistic trauma on i observers, but Dr Volmat goes further and maintains th the public of today is incapable of understanding any co temporary ideas and trends Similar exaggerations mar t last chapter, on art as a means of group therapy few wou agree that patients' paintings are "as useful as all oth sources of clinical observation," or that the act of paint necessarily brings about a therapeutic abreaction

The book ends with 169 black-and-white reproductio —an eloquent, if muted, testimony to the comprehensiv ness of a remarkable exhibition

℞ for Medical Writing

Edwin P Jordan, m d , Willard C Shepard Phil delphia and London W B Saunders 1952 Pp 11 17*s* 6*d*

The first third of this book is a kindly and intima guide to the writing of medical articles The harde thing is to get started many people are familiar with t paralysis induced by a ream of blank paper to be fil by next Monday And when a start is at last made, t pen is apt to run away with the writer Dr Jord explains how to cope with these troubles

He begins with a chapter on preliminaries choosing t subject, reading it up, making notes, and suiting the style the reader Drafting and revision are then discussed length, and there is helpful advice about those importa points the title, the beginning, and the summary Tw thirds of the book is about illustrations and statistics T chapter on illustrations is technical, and though medi illustrators may find it interesting the ordinary medical wri needs something less involved The chapter on statistics also rather heavy going for those who are not statisticians and probably superfluous for those who are It would ha been better to have a much shorter and non technical accou of the subject

Diseases of the Thyroid Gland

Samuel L Gargill, m d , assistant clinical professor medicine, Harvard Medical School Mark Falc Lesses, m d , instructor in medicine at the School N York and London Oxford University Press 1955 9

Reprinted from Oxford Loose-Leaf Medicine, t book treats the subject in a conventional way Chapt on the anatomy, physiology, and biochemistry of thyroid are followed by detailed descriptions of diseases A reasonable balance has been struck betw the theoretical and the practical The authors' opini seem to be strictly orthodox, and it would be difficult find fault with them, although, like most Americ authorities, they may be unduly influenced by incidence of malignant change in nodular goitres T is a sound but not an exciting book, and the illustrati are good

---

Medical Manual of Chemical Warfare (4th ed H Stationery Office 1955 Pp 88 4*s*) —For the new editi this manual, issued under the authority of the Admira War Office, and Air Ministry, has been extensively rev by a committee with Major General A Sachs as its chairm A new chapter on the nerve gases has been added, as wel a table showing the effects of war gases on food and wa A number of mainly industrial hazards, including hydro sulphide, ammonia, and corrosive acids, have been omit or dealt with only briefly, because they will be covered by *Handbook of Occupational Health* which is being prepared the Joint Services and Factory Department Committee Occupational Health Carbon monoxide, however, has b retained, and a new note has been added on gasoline A f section on Anoxia and Oxygen Therapy points out that Schafer method of artificial respiration has now given p to the back pressure/arm lift method of Holger Nielsen, w is clearly described and illustrated As an alternative, for when the arms or shoulder girdle have been injured, hip lift/back-pressure method is proposed

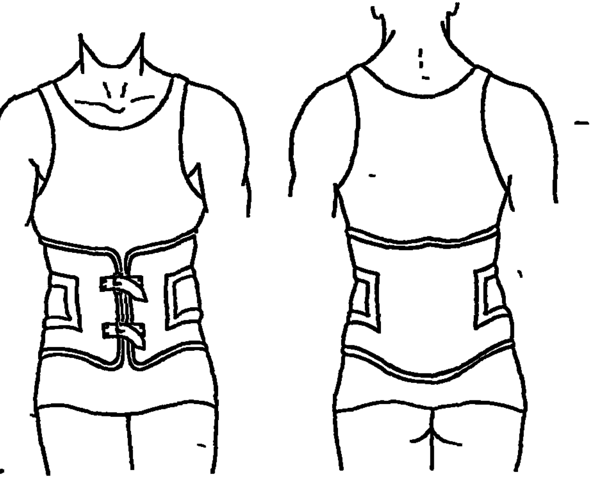

Fig 8—Application of plastic support to patient.

ugh position, a temperature of 120°C The corset is hen placed on the tray with the polyethylene side uppermost and is heated for about 15 minutes The whole of the polyethylene should become clear if it s at the correct temperature It must not be allowed to become too hot because it will then be too soft, like reacle Hence the need for a thermostat as well as a thermometer

Fitting

The corset can be applied with the patient lying prone on the traction couch with its two sections separated, but, if the patient is well enough to stand, this position is preferred because it leads to a better fit The patient then stands with his arms above his head, steadying himself by holding on to a bar He is covered with a layer of stockinet or a vest on which are marked the upper and lower positions for the corset and the midline at the back

The tray with the heated support on it is then removed and laid on top of the oven, and two strips of 2 inch calico bandage are placed on the upper and lower margins of the support These make it easier to hold and lift the support and can be held together in front of the patient so that they are useful in moulding the support They also prevent the material from stretching, which it is liable to do in the soft state The support is then applied to the patient posteriorly, the centre of the support must be made to coincide with the midline of the patient, it is then wrapped round to the front, held by the two calico strips, and bandaged on with two 4 inch openwove bandages It remains in position for a quarter of an hour, by which time it will be cool enough to have set, and is then removed The straps and buckles are applied by riveting in position as shown in figs 6 and 7 The corset is then fitted to the patient, and any minor adjustments are made so that it is absolutely comfortable in both standing and sitting positions Tapes can, if necessary, be attached to the lower bar to hold suspenders, and this is really a useful addition because it prevents the support from riding up

After-treatment

It is recommended that, as a general rule, these supports should be worn for at least six weeks after all symptoms have subsided, but they may be used for even longer periods They can in most cases be taken off when the patient lies down at night and when he wants to have a bath and to carry out hyperextension and straight-leg-raising exercises, and they take the place not only of the plaster corset but also of a Goldthwait's belt subsequently

Return to Work

Plastic supports for the lumbar discs have been most useful in getting the patients back to work, sometimes immediately after the application, provided the work does not entail much bending or lifting Farmers can get round the farm and supervise, bench workers can usually continue, and sedentary workers, such as insurance clerks, bank clerks, solicitors, teachers, and doctors, can do the greater part of their duties In this way many working-hours can be saved, and a man who works for himself does not need to miss much time, for he can be up and about with the lumbar spine supported in an upright position, so that healing can take place probably as rapidly as if he were recumbent

Conclusion

Traction-manipulation has a definite place in relieving a severe attack of pain in cases of prolapse of a lumbar intervertebral disc, and plastic corsets are a great improvement on plaster ones and help to maintain reduction and to prevent recurrences

There is, however, a hard core of patients with prolapsed lumbar intervertebral discs who are not relieved or suffer recurrence in spite of manipulation, supports, or prolonged rest in bed, and in these operation should not be unduly delayed

Every orthopædic surgeon must be familiar with the remark made by a patient after operation when relieved of the excruciating attacks of sciatica "Why didn't you operate sooner?"

Cost

The polyethylene ('Vitrathene') was obtained from Stanley Smith & Co Ltd, Worple Rd, Isleworth, Middlesex, in sheets measuring 7 ft × 3 ft × $^3/_{16}$ in costing £10 12*s* 3*d*, enough to make eight or nine corsets The polyurethane ('Moltopren') was obtained from Kay Bros Ltd, Reddish, Manchester, in sheets 6 ft × 3 ft × $^1/_4$ in costing 15*s* 4*d*, enough to make seven or eight corsets Rivets, buckles, and straps cost less than 2*s* 6*d* per corset, and the time taken by a skilled man to cut out the material is something less than an hour at 4*s* an hour, so the cost of materials used and the man's time for making up the corset come to just over £1 15*s*

I wish to thank the staff of the Norfolk and Norwich Hospital for their coöperation, Miss V Gibson, of the physiotherapy department for not only carrying out many of the manipulations but also for keeping careful record of the effect on the patients, Mr F Baker and the nurses of the orthopædic theatres for help in the application of the plastic supports, and Mr R Fox, the carpenter, for making the original traction couch The specially designed couch was made for me by Rowlands Bros, Aylsham, Norfolk

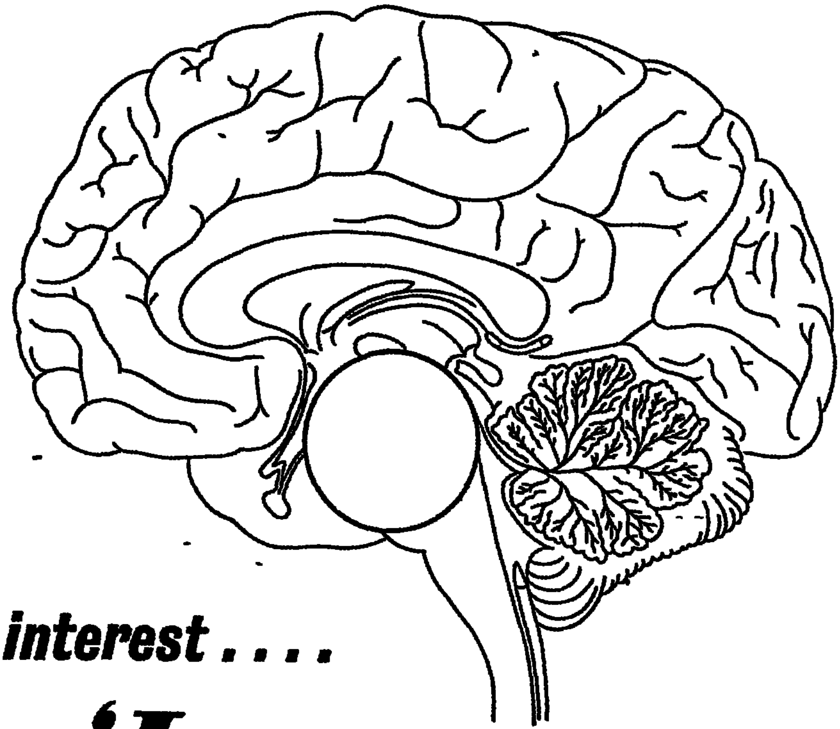
Thrombotic micro angiopathy is characterised by pyrexia, hæmolytic anæmia, thrombocytopenia, and bizarre neurological symptoms It occurs more commonly in females and is of acute onset and fatal outcome At necropsy the gross appearances are neither specific nor striking, and it is usually only when microscopy reveals widespread intracapillary thrombosis that the correct diagnosis is reached

MA310



Still a

drug of

UNUSUAL *interest....*

'Largactil'

trade mark brand

CHLORPROMAZINE HYDROCHLORIDE

A year ago it was just a drug with therapeutic possibilities in general medicine, psychiatry, and anaesthesia. Today, 'Largactil' brand chlorpromazine hydrochloride has been clinically proven and established as a valuable drug for treatment in many serious conditions It is suggested for

1 Control of intractable pain
2 Control of nausea and vomiting
3 Control of motor excitement
4 Relief of tension, anxiety, and apprehension
5 Management of hyperpyrexia
6 Reduction of operative shock
7 Relief of hiccough
8 Relief of pruritus
9 Enhancement of the actions of hypnotics, sedatives and analgesics

Detailed information is available on request Clinical investigations on other possible indications are continuing

PRESENTATIONS

Tablets—10, 25, and 100 mgm Syrup containing 25 mgm. per 3 6 c c (approx 1 teaspoonful) Solutions for injection —1% in 5 c c ampoules 2 5% in 1 c c and 2 c.c. ampoules Suppositories containing 100 mgm base

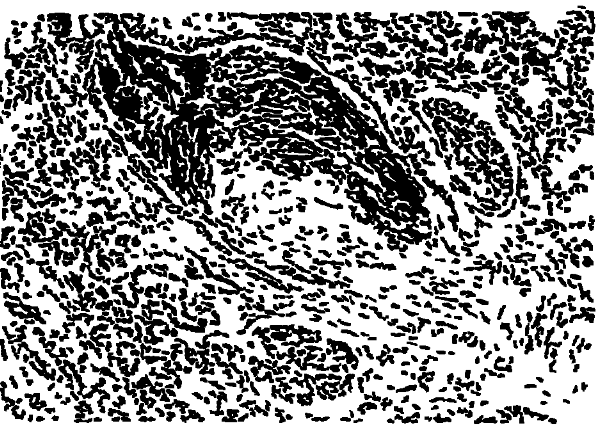

Fig 3—Partially organised thrombus in kidney

(June 11) and her pulse rate was 100 per min. Her blood sugar and blood-urea levels were normal. Her Hb was 51% (Haldane) (7.5 mg per 100 ml.) and reticulocytes 13%. On June 12 her temperature reached 102.4°F, and her pulse rate and respirations increased correspondingly. Fresh crops of petechiæ and numerous bruises appeared on her arms and body. She died in coma on June 14, without having recovered consciousness.

Necropsy findings.—The body showed numerous bruises and purpuric spots. It was very pale, and the conjunctivæ were slightly icteric. The *bone marrow* showed moderate erythroid hyperplasia red marrow occupying the upper two thirds of the medulla of the right femur. The vertebral marrow was uniformly red. The *lungs* were congested and œdematous at both bases, fluid being expressed from them with ease. The *trachea* and *bronchi* were healthy and the related lymph nodes not enlarged. The *pericardium* and pericardial sac appeared normal. The *myocardium* was pale and soft. The *endocardium*, valves, chambers, and arteries of the heart showed no noteworthy features. The *pulmonary and mesenteric vessels* appeared normal. The *œsophagus, stomach*, and *bowel* from duodenum to rectum appeared normal, and there was no hæmorrhage. The *liver* was of normal size and contained an increased amount of iron by the prussian blue reaction. The *gall bladder* and *bile-ducts* appeared normal. There were no pigment stones. The *spleen* was of normal size, dark red, and soft, with indistinct malpighian bodies, and contained an increased amount of iron by the prussian-blue reaction. The *pancreas* appeared normal. Both *kidneys* were smaller than usual (lt. 110 g., rt. 115 g.) Their capsules stripped easily, revealing a smooth surface. The cortex of both kidneys showed slight narrowing and considerable hæmosiderosis by the prussian blue reaction. The medulla was smooth and uniform. The vessels appeared normal. Both *ureters* and the *bladder* were normal. The *adrenal glands* were of usual size, but their cortex was deep-red and extremely congested. The *uterus* was of usual size and contained a small quantity of blood clot. The *skull bones* and *meninges* were normal. The *brain* was sectioned and showed no noteworthy abnormality.

Histology.—The lumina of many small vessels were partly or completely occluded by pink plugs, the so called thrombi (hæmatoxylin and eosin). Some of these were rather granular, whereas others, presumably older, were partially organised. The endothelium of the vessels containing the "thrombi" showed various degrees of swelling and proliferation, which sometimes encompassed the "thrombus". In some instances the vessels appeared dilated, and on occasion a segmental fibrinous deposition was seen in the wall adjacent to the occlusive mass, the fibrinous material lying immediately beneath the endothelium. Most of the affected vessels were of small calibre, arterioles, capillaries, and some venules. In the liver (fig. 1) the lesions were confined to the small vessels of the portal tracts. In the adrenal gland (fig. 2) the vessels in the capsular zone were much affected, and numerous microscopic hæmorrhages were present. "Thrombi" were numerous in the small vessels of the liver, the kidneys (fig. 3), the capsular zone of the adrenal glands, and the pars nervosa of the pituitary gland (fig. 4). They were scanty in the spleen and absent in sections of bone marrow, skin, lung, endometrium, uterus, and pars distalis of the pituitary gland.

Experimental Observations

The appearances and staining characters of the "thrombi" obtained in the present case were compared with pure platelets and fibrin.

Material and Methods

(1) A centrifuged deposit of human platelets was obtained by the method of Dillard et al. (1951). Smears from this deposit showed large numbers of well preserved platelets relatively little contaminated by leucocytes. This material, subsequently referred to as the platelet mass, was fixed in formol corrosive sublimate, and paraffin sections were prepared in the usual way.

ut sufficient evidence is accumulating to that pathologists should direct more attention to . Meanwhile, another aspect of cancer cytology, hardly appreciated in the clinical field as yet, but ultimately likely to affect clinical thought and practice more deeply than the diagnostic side, is advancing rapidly Malignant change can be maintained in successive generations of cancer cells belonging to one tumour by a persistent external stimulus, as may be provided by hormones in some breast cancers, but this phenomenon could also be explained by a transmissible, or hereditary, change within the cancer cell once it has been born Such a change must take place in those parts of the nucleus, chromosome, or cytoplasm responsible for inheritance The large size of the cancer cell's nucleus compared with its normal parent cell has long been noted[10] Furthermore, there is an increase in chromatin content, and the same is sometimes true of precancerous states[11] and cancer in situ This can readily be explained by an increased number of chromosomes, which are often found to be tetraploid or polyploid in cells from tumours of both man and mouse[12] Boivin et al[13] have shown a quantitative relationship between desoxyribonucleic acid (D N A) and the number of chromosomes in normal cells from the same species The work of Leuchtenberger et al[14] reveals an increase in D N A content of malignant cells, and this appears to correlate with the degree of polyploidy of those cells Is malignancy related to this increase in chromatin content and D N A ? It is significant that the nucleoprotein responsible for papillomata in cotton-tail rabbits contains D N A , but this infective agent finds its place in cytoplasm rather than nucleus Gigantism can be induced by chemical trauma, and advantage is taken of this by horticulturalists who induce polyploidy by painting seeds with colchicum in order to grow bigger and better plants But it is a far cry from gigantism to malignancy, and there are some growths, lymphoma in particular, which show few cells with more than diploid nuclei During a period of regression after irradiation, or treatment with nitrogen mustard, the morphological changes in the nuclei, which then show decreased mitosis, vary from pyknosis to enlargement sometimes associated with chromasia Similar changes induced by triethylene melamine in animals with experimental tumours have been accompanied by a greater increase than expected in the quantity of nucleic acids[15], Mellors[12] suggests that the nucleic acids accumulated because they were synthesised but not used when mitosis decreased In that case D N A could hardly be the chemical substance carrying the heredity of malignancy, unless its molecular arrangement had been altered, thus robbing it of this power It is theoretically possible that ribonucleic acid (R N A) may play a part since the organic mass of fat-free chromosomes, studied by interferometry, reveals in the mouse that D N A is linked with histone and R N A with non-histone protein The R N A complex seems to vary and the D N A complex remains constant, so it is conceivable that R N A provides the variation neede for differences in cell function within the body, whil D N A confers the characteristics of the individual If so, is malignancy carried with the variable factor The solution to these problems may turn the attentio of diagnostic cytologists to cytochemistry—and Leuchtenberger et al[14] have already suggeste D N A evaluations as a diagnostic cytochemical tes for malignancy

Infectivity of Nucleic Acids

During the past ten years or so advances in our knowledge of how viruses multiply have come mainl from intensive investigations of the bacteriophage Most bacteriophages seem to consist of a core o desoxyribonucleic acid with a protein overcoat, and one of the most exciting recent events was the demonstration by Hershey and Chase[16] that when bacteriophages infect their bacterial hosts the virus nucle acid enters the host cell while the greater part o the virus protein remains outside the bacteriu Evidently the chief function of the protein is to ac as a vehicle for the all-important nucleic acid, and once the protein has transported the nucleic acid t a new host bacterium, it can be dispensed with in th following stages of multiplication

At the moment, however, progress towards a bette understanding of virus multiplication seems to b coming mainly from studies of tobacco mosaic virus In this virus, the rod-shaped particles have a core o ribonucleic acid surrounded by a protein shell, an recently Fraenkel-Conrat and Williams[17] foun that the nucleic acid and protein could be separate from one another and then reconstituted Th reconstitution was shown convincingly by electro microscopy, and it was also found that some of th infectivity of the original preparation was restored Lately, Fraenkel-Conrat[18] recorded that when th nucleic acid of one strain of tobacco mosaic virus wa mixed with the protein of a second strain, recon stitution again occurred The reconstituted viru behaved serologically like the strain from which th protein was derived, but when the reconstituted viru multiplied, its progeny showed all the characters of th strain from which the nucleic acid was derived Fraenkel-Conrat also noticed some infectivit associated with the nucleic acid alone, this infectivit was unstable and it was susceptible to the action of th enzyme ribonuclease Both these characters differenti ate this infective behaviour from that of the intac virus and Fraenkel-Conrat suggested that it migh be a property of the nucleic acid itself Now, Giere and Schramm[19] have produced strong evidence tha the ribonucleic acid of tobacco-mosaic virus may b infective alone The basis of their evidence is that pure preparation of ribonucleic acid from which th protein was removed was still infective "th infectivity of the ribonucleic acid preparation is about 2 per cent of that of the native virus" Th infectivity of the nucleic acid was not neutralised b antiserum to the whole virus, since antibody effective against the protein part of the virus onl Like Fraenkel-Conrat, Gierer and Schra orm is interfered with, and a type of fibrin produced hose morphology differs from the classical fibrillar form may therefore be concluded that the occlusive material, ough it may contain platelets, is composed mainly of substance that could be compact fibrin Further riticism of the platelet composition of the occlusive ass is offered independently by Fisher and Creed (1955), who, using the staining technique of Glynn and Loewi 1952), believe the occlusive masses are "fibrinoid"

Primary damage to the endothelium as the cause of he coagulum, suggested first by Altschule (1942), eemed to Engel et al (1947) and Trobaugh et al (1946) to e confirmed by their findings of endothelial swelling and roliferation in vessels without thrombi Similar changes were found in two cases by Fitzgerald et al (1947), who are not quite prepared to say that this endothelial change s the precursor of the coagulation Others have failed o find these endothelial changes (Baehr et al 1936, Bernheim 1943, Singer et al 1947) In the present case the overwhelming majority of non-thrombosed vessels appear normal

A different prethrombotic lesion is described by Gore (1950) and by Meacham et al (1951) a segmental accumulation of hyaline material lying below the intact endothelium Meacham et al suggest that increase in the amount of this material eventuates in the intraluminal mass, but they do not record any extension of the so called hyaline material outwards into the other structures of the vessel wall A similar focus of fibrinoid change in the vessel wall is thought by Allen (1951) to be the site of initiation of the thrombi, and he suggests that this disease, which he calls generalised arteriolocapillary thrombonecrosis, may be due to allergy

The hypothesis of primary damage to the terminal portion of the vascular tree has been favourably reviewed by March (1954), and in the present case a few vessels contained deposits of subendothelial material staining like fibrin and apparently in continuity with the intraluminal coagulum This hypothesis, however, is open to two criticisms

(1) "Thrombi" were commonly seen in vessels which otherwise appeared normal, but the "thrombi" may have propagated themselves along the vessel from a small focal point of mural damage

(2) Deposition of subendothelial fibrin, with a curious absence of accompanying thrombosis within the lumen, takes place in the three forms of fibrinous vasculosis described by Lendrum (1955) stagnant, hypertensive, and hyperergic

Thus some other factor, over and above the deposition of subendothelial fibrin, seems to be involved in the formation of the intraluminal thrombosis in this disease

The hyperergic basis of disseminated capillary fibrin thrombi is strongly supported by Pagel (1949, 1951), who suggests that the antigens act on the vessel walls, and the possibility that thrombotic thrombocytopenic purpura should be included in the group of diseases studied by Pagel (dermatomyositis and disseminated lupus erythematosus) is strengthened by Symmers and Gillett's (1951) description of a case showing features of lupus erythematosus, polyarteritis nodosa, and thrombotic thrombocytopenic purpura Moreover, Laszlo et al (1955) have published a case in which the features of thrombotic thrombocytopenic purpura were associated with disseminated lupus erythematosus Compared with polyarteritis nodosa, drug-induced arteritis, and disseminated lupus erythematosus, there is certainly little cellular reaction around the involved vessels of thrombotic thrombocytopenic purpura, but it is probably unjustifiable to make too much of this distinction This interpretation of the histological appearances, which suggest a hyperergic reaction of the vessel wall, is accepted by Dameshek (1955), who believes that this disease is a triple auto immune disorder affecting three tissues red cells, platelets, and small blood-vessels

It may be concluded that, in thrombotic thrombocytopenic purpura, there is some factor at work which determines the site of the "thrombi" in the precapillary arterioles, that the "thrombi" are largely composed of compact fibrin, and that there is some upset of the permeability of the vessels at these sites to explain the occasional presence of fibrin within the wall

From the clinical point of view it is rather galling to realise that, once again, this disease was unrecognised during life because of lack of knowledge of an established clinical entity We feel that this is the factor which maintains thrombotic thrombocytopenic purpura in its present position as a "rare" disease We wonder how many cases of "cerebral thrombosis," &c, have also had pyrexia, anæmia with slight icterus, and perhaps a few petechiæ We reiterate the suggestion of Symmers (1952) that either corticotrophin or cortisone might be used in the treatment of future cases Symmers (1952) gives an admirable survey of treatment used in the past

Summary

A case of thrombotic thrombocytopenic purpura is described

The staining reactions of the "thrombi" are compared with those of platelets and of naturally occurring fibrin. The results indicate a close similarity of the "thrombi" to fibrin rather than to platelets

The following conclusions are reached

(1) Some factor determines the site of the "thrombi" in the precapillary arterioles

(2) The "thrombi" are composed largely of compact fibrin

(3) Altered permeability of the vessels at these sites explains the occasional presence of fibrin within the wall

We wish to thank Prof D F Cappell for valuable assistance in the earlier part of this work, Prof A C Lendrum for his aid in Dundee, where the work was continued, Dr D K. Adams, in whose wards the patient was first seen, for encouragement and advice, and Dr H E Hutchison for interpreting the appearances of the biopsy specimen of bone marrow

considerable, amounting, in terms of money, labour, and materials, to a value about half of what is spent by the government Important assistance has also been given by the United States government and the Ford Foundation, amounting to a quarter of the total cost Since its inception the main scheme has been supplemented by a preparatory one which, at the expense of restricting objectives, will provide some of the benefits for a greater number of people

For doctors, however, a noteworthy feature of the project is its comprehensiveness, which exceeds that of community development programmes in other countries Speaking at the conference, Dr JOHN B GRANT, of the Rockefeller Foundation, who is now professor of public health and medical care at the University of Puerto Rico, outlined principles for the development of backward areas

> The success of an attempt to eliminate poverty, disease, or ignorance depends, he said, on how far it is undertaken as part of "multi-purpose community development," and the project must be within the framework of a national plan for industry as well as welfare The programme must be based on practical economics—e g, on whether the number of doctors the country can afford is one per 1000 of the population, or one per 10,000, and whether the number of hospital beds is four per 1000 or only one per 1000 Each level of government—national, State, and district—requires, in Dr GRANT's view, a development organisation with coordinating and planning functions, designed to *act as a catalyst, not as an executive agency* The success of technical assistance depends on the degree to which it can mobilise voluntary self-help, and this in turn depends on the extent to which consciousness of local needs is generated in the community through its village councils The unit of organisation for community development must, he believes, be technically self-contained, providing its own services, supplies, and supervision empirically it has been found that the population it serves should not be less than 200,000 or more than 500,000, *and its area should coincide* with that of a previously existing administrative unit of government, with which it can be integrated No less important are the steps that must be taken to ensure local *initiation* of the plan according to the determined needs and it is similarly essential to provide for continuous representation from the village level to the highest organs of the State Finally, *a development programme must* provide for the training of personnel and for independent assessment and criticism of the project as a whole

Concluding his survey, Dr GRANT said that, by its adherence to essential precepts, the present plan seems to have placed India well in advance of other countries which have undertaken community development

But though the technique of village development, as he said, has been carefully studied and many schemes have been successful, it remains to be seen how such techniques will bear fruit on the historic soil of India The difficulties are immense, and it is not surprising that one can find, dotted about India, defunct small-scale schemes, with and without Evangelical backgrounds The Indian village has a remarkable capacity for absorbing (quite amiably) outside endeavour, and for having absolutely nothing to show for it ten years later Continuity of policy and adequate funds will thus be essential if the present project is to succeed and if India is to show how democratic methods can be applied in a field too often the preserve of the authoritarian theorist A five-year plan is a beginning, but what are five years among so many hundreds? If the slip back to old habits is to be avoided, the government must be prepared to extend the work in each block for a second, third, and even fourth five year period At present its exact intentions are not clear, but it evidently expects to cover the entire country with its community development programme during the second five-year plan (1956–57 to 1960–61)[1] This is a formidable task indeed, and it remains to be seen what will be the effects of the changing attitude of India towards American aid, and of the present internal unrest Certainly the financial burden will fall heavily on a country as poor as India, and we of the West ought to be prepared individually and nationally to do what we can to help For this vast and well-conceived experiment must not be allowed to fail for want of aid that we are able to offer

Annotations

TUBERCULOSIS IN THE TROPICS

THE waning of *tuberculosis* in Britain and other countries well supplied with hospital and other resources is not yet evident in less favoured areas, and there is no certainty that the methods which are proving effective here will be equally effective in different cultural, environmental, epidemiological, *and nutritional* conditions Even the causal bacillus may not be the one we know As Dr M G Candau, director general of W H O, remarks in his latest annual report[2] "There is increasing evidence that mycobacteria isolated from patients in tropical *areas* may differ, in type and in other particulars, from those which are defined at present as tubercle bacilli" Chemotherapy, without admission to hospital, may help to control tuberculosis in lands where the disease is rife, but we are not yet certain that it will, and meanwhile its use with imperfect supervision may be actually increasing the load of infection in communities by prolonging the lives of patients without rendering them non infective, and by promoting the spread of drug-resistant organisms

An important step *to solve* these problems has now been taken by W H O in conjunction with the Medical Research Council and the Indian Council for Medical Research An international research unit, selected by the M R C, is to conduct a five year survey *in* Madras In the first stage, which may take two years or more, a group of patients treated by various drug régime without being admitted to hospital will be studied for sputum conversion and compared with a reference group admitted to hospital If this stage goes well a second stage—probably an investigation of the community effects of widespread domiciliary chemotherapy—will be considered

Not the least important aspect of this venture may be the opportunity to train counterpart personnel with a view to establishing permanent cadres in clinical and bacteriological research The two vacancies on the unit announced in our advertisement columns this week comprise one for a bacteriologist, and one for a chest physician who will undertake some postgraduate teaching The unit's task will be difficult, but it should prove rewarding

NEW ANALGESICS

IN their continuous search for new analgesics with fewer side effects than those drugs in common use, pharmacologists commonly investigate the effect of variations in the basic molecule of one of the established analgesics Thus, Millar and Stephenson[3] have recently

SENIOR MEDICAL OFFICER, BELFAST HEALTH DEPARTMENT

In preparation for field and serological studies of poliomyelitis vaccine in Northern Ireland, investigations were started in the spring of 1955 to find children with little or no antibody to any of the three types of poliovirus

Arrangements were made with the borough and county medical officers of health to take samples of blood from some of the children in nursery or primary schools or from other children of similar age—i e, 2–9 years In addition a few samples of blood were obtained in some areas from children aged 1 year All the samples were selected, in that mothers were invited to give permission for their children to be bled, in the knowledge that they would be *offered* vaccination when a suitable vaccine became available Except the samples taken in September from the Belfast children aged 1 year, the sera were collected between May and July, 1955 *

Materials and Methods

Sera were stored at –20°C and inactivated at 56°C for 30 minutes before testing

Tissue cultures were either first or second pass monkey-kidney cell monolayers in roller tubes The methods described by Melnick (1955) for preparing these cultures were used, except that a simplified apparatus was used for the continuous digestion of monkey kidney and 6–12 oz medical flat bottles were substituted for Roux bottles in the preparation of second passage cells Lactalbumen medium (Melnick 1955) was used both for cultures and as a diluent for sera and virus suspensions

Virus strains, obtained from Dr A. Goffe, of the Wellcome Research Laboratories, were type 1, Brunhilde, type 2, Y-SK, and type 3, Leon

Tissue-culture Neutralisation Test—Sera were tested at a 1 in 4 dilution against an estimated 100 TCD$_{50}$ of virus Equal volumes of a 1 in 2 dilution of sera and virus suspensions containing 200 TCD$_{50}$ were mixed and allowed to stand at room-temperature for one hour Culture tubes containing 1 5 ml of medium were then inoculated with 0 5 ml of the virus serum mixtures and placed in roller drums at 37°C Two tubes were used in testing each serum against each type of virus Cultures were examined on the sixth day Only those sera which protected both duplicate tubes were considered positive In all the tests the virus suspensions and known positive control sera were titrated

Results

The detailed results of the survey are shown in table I, and figs 1 and 2 We do not claim that these results represent the serological pattern in all children of a particular age group in Northern Ireland.

Table I shows that antibody to each of the three types of poliovirus was present in children in all the areas studied In the Belfast sample the rates among children in private schools were much lower than in nursery and primary-school children—e g, only 1 of 25 (4%) in the former group had antibody to all three types of virus, compared with 83 of 128 (64 8%) of the nursery and primary school children (Social factors, which may be related to the antibody patterns found in the children in this survey, are being investigated by Dr E M Backett, of the department of social medicine, Queen's University, Belfast)

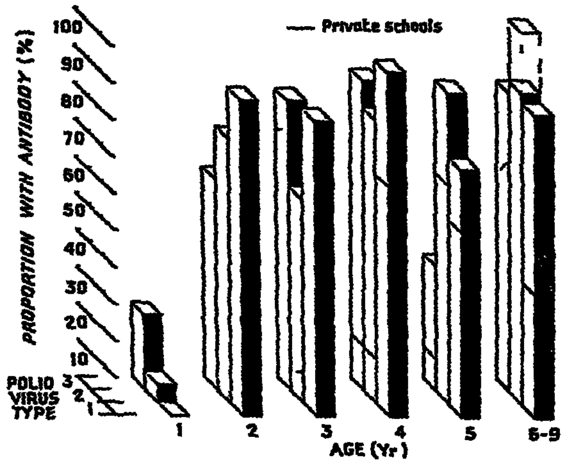

Fig 1—Percentages of children in Belfast and Londonderry boroughs with antibody to three poliovirus types in different age-groups. Interrupted line refers to children from private schools

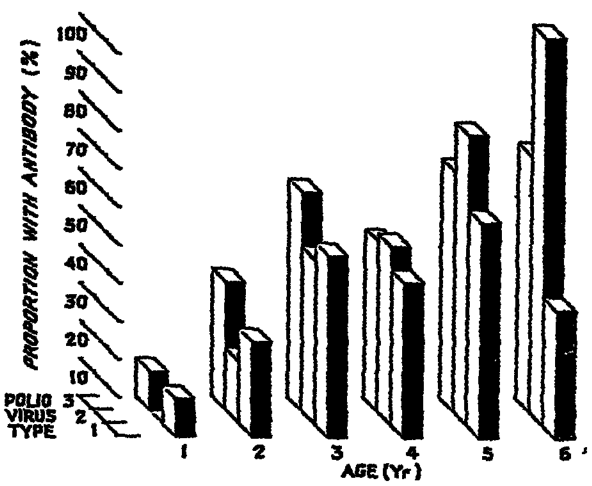

Fig 2—Percentages of children in counties of Northern Ireland with antibody to three poliovirus types in different age-groups

The antibody-rates in the boroughs of Belfast and Londonderry were usually higher than in the counties, of which co Tyrone had the lowest rates (table I)

It was incidentally observed that samples had been obtained from 28 pairs of siblings and from 3 siblings of one family

The results of tests on the sera from the siblings are shown in table II, which shows that both children in 18 pairs of siblings had the same antibody response, and the older child in 10 pairs of siblings had one additional type of antibody In only 1 pair of siblings had the younger child antibody not possessed by the older child This observation is in agreement with the evidence of Fox et al (1955), Brown et al (1954), and others, that when polio-the electron microscope The symptoms of panniculitis —the *peau d'orange* and the paræsthesia—Baker attributes to the tension which arises when normal subcutaneous fat increases rapidly beneath a thickened and largely inextensible corium How the skin changes, and what the change signifies, we do not know The clinical condition is usually self-limiting, and improves if weight is reduced and sodium intake restricted Its appearance at the time of the menopause suggests some hormonal factor, and it may be worth recalling that at other times of rapid change of hormonal activity—pregnancy and the puerperium—there are striking changes in collagen content in, for example, the uterus.

* Sera from co Armagh, which were received during January, 1956 have not been tested

SPLEENS THAT ARE LEFT

THE indications for the removal of enlarged spleens and the results of the operation are subjects which have provoked much discussion It is often difficult, however, to assess the value of the operation because we do not know what happens to patients with similarly obtrusive viscera who, for one reason or another, retain their spleens The need for this sort of information was pointed out in 1938 by Howells [1] He compared the results in 53 patients with Banti's disease who had their spleens removed with a similar series of 43 patients who retained their spleens, so far as expectation of life and anæmia were concerned, there was no significant difference between the two groups Jordan and Heck,[2] of the Mayo Clinic, have recently tackled this question again and their results are valuable and interesting

They reviewed the records of all patients seen at the clinic between 1930 and 1945 who were diagnosed as Banti's disease or syndrome, splenic anæmia, or congestive splenomegaly, and who did *not* have their spleens removed They concede that it is likely that some of these patients would today be diagnosed as hypersplenism—or more specifically as splenic neutropenia or splenic pancytopenia Nor is it always clear from the records how many of the cases listed as Banti's disease had primary cirrhosis of the liver Jordan and Heck have not attempted to make retrospective diagnoses, they give the details so that the reader can form his own opinion In the selected period there were 98 patients who had been followed for five years or more and whose records were therefore worth studying These 98 patients are divided into three groups in group 1 are 34 patients who declined to follow their physician's advice to have their spleen removed, in group 2 are 28 patients with a definite diagnosis but who for some reason were advised not to have a splenectomy (in 11 the risk was said to be too great, and in 3 the disease was not thought to be sufficiently severe), group 3 includes 36 patients with similar clinical and laboratory findings to the other groups, but for some reason the clinician was not sure about the diagnosis and therefore did not recommend removal of the spleen

The records show that 49 patients (exactly half) survived for more than five years after they were first seen in the clinic, and the five year survival-rate of 50% applies also to each of the three groups separately The list of causes of death shows that more patients in group 1 died of gastro intestinal hæmorrhage than in the other groups, and this reflects current opinion that such bleeding is a good indication for splenectomy For comparison with this group, there have been several reports on survival in Banti's disease after splenectomy, and, on the whole, results are no better For example, Pemberton and Kiernan,[3] also working in the Mayo Clinic, had a five year survival rate of 54 8%, though it has to be remembered that more of their patients had bleeding œsophageal varices than those who kept their spleens Jordan and Heck also found that the only reliable guide to prognosis was the bromsulphalein retention test for liver function, and there was a direct correlation between the degree of retention of the dye and the five-year survival, thus, 72% of the patients with normal excretion of the dye (i e, less than 6% retention after one hour) survived, whereas in those who retained 6–11% of the dye in the blood after one hour, the survival was 54%, and so on Some surprising stories are included to illustrate what may happen to these patients A man of 42 was first seen in 1908 with spleen and liver enlarged to the level of the umbilicus, hæmoglobin 40%, and white cells 8280 per c mm A diagnosis of splenic anæmia was made and no treatment was given In 1950, at the age of 84, he was reported in good health, having survived a gastroenterostomy for obstructing duodenal ulcer at the age of 66, the spleen was found to be enlarged then A physician of 56 was seen in 1935 with spleen enlarged to umbilical level normal hæmoglobin, white cells 3500 per c mm, and platelets reduced to 73,000–90,000 per c mm Splenectomy was advised but declined, and fifteen years later he felt fine and had successfully undergone a prostatectomy

Jordan and Heck reasonably conclude that splenomegaly with hypersplenism is not alone a firm indication for splenectomy The operation should be advised "only for those patients whose symptoms are severe enough to justify the surgical risk, it should not be advised simply to correct some deficiency of the cellular elements With this opinion most physicians who see such cases will agree, the signs, symptoms, or complications in addition to the splenomegaly must be taken into account when deciding whether or not to operate Of course such retrospective surveys can give only a rough comparison because nowadays a much more precise diagnosis is possible, and "Banti's disease or syndrome" is much less of an omnibus diagnosis than it was The leukæmias the reticuloses, and conditions like myelosclerosis can all be distinguished, and the presence of gastro intestinal hæmorrhages with signs of portal hypertension should lead to careful consideration of the value of a portacaval shunt

FULL MILITARY HONOURS

SIX years ago we announced,[1] with great regret, that the *Index-Catalogue* of the United States Army Medical Library at Washington would have to end with the eleventh volume of its fourth series This elegiac volume (Mh–Mn) has now appeared, and medical workers in libraries, laboratories, and lecture rooms all over the world will receive it sadly

For the past 35 years the *Index* has been vainly struggling to keep pace with the rising tide of monographs and papers Each year it fell further behind, and by 1950 it had a file of 1¹/₄ million unpublished items which was growing at the rate of 200,000 items a year Publication was at the rate of a volume of 80,000 references every three years By 1958, it was estimated, there would be an unpublished backlog of over 3 million references—more than all the *Index Catalogue* had been able to publish since it first appeared in 1880 A surfeit can be more embarrassing than a deficit, and the Surgeon-General's Library has had to admit defeat, but it is publishing "selected monographic material" from the backlog, and it has revised the form of its monthly *Current List of Medical Literature*, which now includes 100,000 items annually and semi annual cumulations of author and subject indexes The library now also publishes an annual catalogue of monographs and this year the first five year cumulation has appeared

The 3 million references contained in the 58 volumes of the *Index-Catalogue* will be a permanent memorial to ndings suggest that type 1 virus may have been of most importance in producing paralysis in Northern reland in recent years.

---

[1] *Lancet* 1950 i 426

It is emphasised that our samples were taken not as part of an epidemiological investigation but to define a population group with low levels of antibody. Nevertheless the epidemiological data from Northern Ireland show that low antibody-rates were found in young children in the areas with the lowest paralysis rates in that age group.

It is generally accepted that the age distribution of paralytic poliomyelitis in any population indicates the state of immunity of the different age groups, and this appears to be the case in Northern Ireland, if the selected samples were representative.

We conclude from the results (tables I and III) that the serological responses to vaccination might best be studied in the 0–4-year age-group in co. Londonderry, co. Fermanagh, or co. Tyrone, and it appears that a similar conclusion might have been reached by examining the paralysis-rates in that age group (table III).

Summary

A survey was made to find a group of children in Northern Ireland with low rates of antibody to the three types of poliovirus, in preparation for serological and field studies with poliomyelitis vaccine.

A high incidence of naturally acquired immunity to all three types of poliovirus occurs at an early age in the children of most areas studied in Northern Ireland. In Belfast the incidence was highest in children attending nursery and primary schools but was lower in children attending private schools. In general there was a lower incidence in the counties, of which co. Tyrone had the lowest rates.

The results of tests on sera from siblings agree with previous observations on the concurrent infections of family associates.

Provided that the groups of children examined were representative of all children in their age group, it appears that the paralysis-rate in a given age group in Northern Ireland is a good index of the immune status of that age group.

TABLE III—COMPARISON OF AVERAGE ANNUAL AGE SPECIFIC PARALYSIS RATE IN CHILDREN AGED 0–4 YEARS (1950–55) AND PERCENTAGE OF THAT AGE GROUP WITH ANTIBODIES

Place	Paralysis rate (per 10,000)	Percentage of sample with antibody to type		
		1	2	3
Belfast Borough	4·47	73·2	55·7	71·1
Londonderry Borough	8·85	61·5	42·3	42·3
Co. Antrim	3·87	56·2	43·7	68·7
„ Armagh	3·68	?	?	?
„ Down	3·28	50·0	50·0	28·6
„ Londonderry *	2·55	43·8	35·7	57·1
„ Fermanagh	1·19	28·6	35·7	53·6
Tyrone	2·31	15·8	10·5	5·3

* Among the notified cases in this age group were 9 in which no information was available about the presence or absence of paralysis. Since some of these children might have had paralysis, the paralysis rate for co. Londonderry may be slightly higher.

We wish to thank all the borough, county, and divisional medical officers in Northern Ireland for assistance in collecting the samples of blood and for providing epidemiological data; and the medical superintendent and staff of the Northern Ireland Fever Hospital for data on Belfast cases. Before this laboratory was equipped, sera were kindly tested by Dr. W. Wood, of Glaxo Laboratories Ltd., and at the Virus Reference Laboratory, Colindale; we are most grateful to them for their assistance. This investigation was aided by grants from the National Fund for Poliomyelitis Research and the Northern Ireland Hospitals' Authority. Much of the basic equipment for virus research in the department of microbiology of the Queen's University, Belfast, was provided by a grant from the Rockefeller Foundation.

ACUTE MYOCARDIAL TOXOPLASMOSIS

R. E. POTTS
B.Sc., M.B. Glasg.
PATHOLOGIST

A. ALUN WILLIAMS
M.D. Lond., M.R.C.P.E.
PHYSICIAN

TEES SIDE HOSPITALS

TOXOPLASMOSIS, both congenital and acquired, is still regarded as a rarity. Most of the cases reported in this country have been of the congenital variety in children. Paulley et al. (1954) reported 3 cases of myocardial toxoplasmosis in adults, in which the diagnosis was based on a positive dye test and a positive complement-fixation test. They believed their cases to be chronic acquired myocardial toxoplasmosis.

The acquired form has also been known to take an acute course resembling typhus (Pinkerton and Henderson 1941), often with electrocardiographic changes.

Siim (1951) has reported a more benign syndrome associated with generalised lymphadenopathy and resembling glandular fever. Cathie (1954) has isolated toxoplasma from such cases.

We report here an acute fatal case, predominantly myocardial, in an adult.

Case-report

A male police detective, aged 30, was admitted to hospital on Sept. 21, 1954, complaining of bronchial symptoms of two weeks' duration. For the previous two months he had had vague malaise associated with a persistent head cold. The cough was productive of purulent sputum, but there had been no hæmoptysis. Before admission penicillin and erythromycin had been prescribed by the family doctor. There was no history of any previous illness. In his youth the patient had worked on a farm but he for many years had not been associated with farming. His family history was unremarkable.

On admission his temperature was 101°F, and he had gross tachycardia (pulse rate 128) with a systolic murmur at the apex of the heart. Blood pressure 85/60 mm. Hg. There were signs of acute pulmonary œdema but no evidence of congestive heart failure. The other systems were normal. Radiography of the chest showed severe pulmonary congestion with moderate enlargement of the heart to the left. Electrocardiography showed a left bundle branch block. A blood-count showed Hb 96%, and white cells 9700 per c.mm. (differential count normal).

Treatment and course.—After investigation it was considered that he had a myocarditis of undetermined origin, possibly of the Fiedler type. The tachycardia was only partially controlled by digoxin 1 mg. daily. Further courses of penicillin and aureomycin were given. Theophylline mono ethanolamine and 'Neptal' relieved the pulmonary symptoms a little. Further electrocardiography during the illness showed left bundle branch block. The patient's temperature was undulating, rising to 102°F. The patient became very confused. Examination of the cerebrospinal fluid on Nov. 8, 1954, showed cells less than 1 per c.mm., protein 15 mg. per 100 ml., no increased amount of globulin, and a negative Wassermann reaction. The dye test for toxoplasmosis on Oct. 7, 1954, was positive 1 : 32 and the complement fixation test positive 1 : 8. Dr. I. A. B. Cathie (personal communication) considered these results significant and advised the administration of pyrimethamine and a sulpha drug. A course of pyrimethamine 50 mg. daily and sulphamethazine 1 g. six-hourly was started on Oct. 29, 1954, and continued for seven days, but there was no response to treatment. By Nov. 10, 1954, sacral œdema and enlargement of the liver had developed. The mental confusion was now more obvious. A week before death a transient erythema appeared on the trunk, with a few petechial hæmorrhages on the left lower chest. During this period

TYPES OF STEALING

JOHN RICH
M D Lond , D P M
SENIOR REGISTRAR, MAUDSLEY HOSPITAL, LONDON

THIS paper describes an attempt to validate, by statistical methods, some of the concepts used by psychiatrists in their reports to juvenile courts The hypothesis to be tested was that "syndromes" of stealing can be recognised, each of which is shown by a boy with a particular predisposition and each of which has a characteristic age of onset and course A basic assumption was that in children the motives for stealing are largely unconscious and that, even where there are other superficial factors, these unconscious motives will determine the form of the theft In other words, whether or not a boy steals may be determined by training, opportunity and so on , but if he does steal, then the way in which he steals will reflect his unconscious drives These drives are not necessarily neurotic or abnormal simply because they are unconscious On the other hand, in some boys the drive is undoubtedly neurotic

Material and Methods

The study was made in three parts The first, involving about 200 boys, was descriptive, for the purpose of clarifying concepts Information on the next 100 boys was quantified and allowed a further modification of ideas The final study, on 200 boys, is the one reported here

These 200 boys, so far as was administratively possible, were consecutive admissions to Stamford House remand home, who had been charged with theft, and remanded *for psychiatric report* *No control group was needed, for* types within this sample are compared with each other and not with an assumed normality As about a fifth of the boys who appear in the London courts are referred for psychiatric examination , as there are six courts with changing benches , and as magistrates differ on the points which call for a report, the sample is more representative than might be supposed It is certainly more representative than the samples drawn from child *guidance clinics*

The offence with which the boy was charged was placed in one of five categories, which were derived from descriptions in the literature modified by the first two parts of the study Various items of information about the boy were recorded, and the type of offence was then compared with this information

Marauding Offences

These are carried out by three or more boys They are unplanned or "semi-planned" Semi-planned means that the boys have not formally agreed to carry out a particular theft, but if the opportunity arises (such as an open window) they take it for granted that they will pick up whatever is accessible They may be wandering around a big store, not wanting anything in particular, but stealing attractive goods which they often throw away again afterwards There is often a considerable and deliberately chosen risk in these escapades, but this element *did not have to* be present for the offence to be classified as marauding

Proving Offences

This name was chosen because these offences are usually attempts to prove one's toughness or manhood They were thought to be more in the nature of self-reassurance than an attempt to achieve "peer status" as in the marauding offences These offences were arranged in the following subdivisions

(*a*) Breaking and entering alone (but not including the "secondary" offence defined below) *These offences, it was* later decided, should not have been included among the proving offences

(*b*) Any form of theft carried out alone *if the stolen* goods are exhibited, if a symbol of dominance is stolen (such as a gun, or a racing bike if the boy uses it in an ostentatious way), or if the boy is obviously showing off to *one* less experienced or younger

(*c*) Taking and driving away a motor vehicle

Comforting Offences

These offences fell into two groups

(*a*) Stealing from parents
(*b*) Impulsive pilfering alone or with one other boy

Secondary Offences

Planned theft of any sort, alone or with others of similar type, with a definite idea of what can be stolen, with reasonable precautions against detection

Other Offences

Any offence which could not be placed in one of the above categories, including doubtful cases Examples were—stealing under instructions from father, stealing food after having run away from home, and stealing coke to help a sick mother

The following information was collected about the boy his age , his height, weight physical condition sexual development, and intelligence (all transformed into standard deviations) , the socio economic level of his home , the age of his first known theft , whether he had stolen from home at any time , details of separation from mother before the age of 5 , length of breast feeding, and—an essential feature—his parents' attitude towards him

The *information* was *collected* from an interview with the boy, the probation officer's report, the London County Council education department's records including a school report, the case record or a report from any child guidance clinic the boy attended, and *a full social* history taken by the psychiatric social worker at Stamford *House*, Mrs McConville *The parent's* attitude was assessed independently by the probation officer, by the psychiatric social worker, and by myself It was not always possible to make three assessments but unle there were two in agreement on a given variable, the attitude was recorded as unknown On democracy, acceptance, and indulgence—the definitions of these terms being derived from the paper by Baldwin, Kalhorn and Breese (1945) working with the Fels scale—the *attitudes* were recorded as high, medium, low, inconsistent, or "not applicable" Each parent was rated independently of the other

Discussion

Many writers, from Healy (1915) onwards, have pointed out that delinquents cannot be considered a homogeneous group, though some speak of "the delinquent" as if all young offenders were hardened *antisocial* characters Friedlander (1947) takes this latter view, while the Gluecks (1950) finally conclude that "the delinquent group is a composite of several sub types" The proponents of the "typical young delinquent" school of thought are often psychiatrists working in a clinic, and it is reasonable to suppose that the material they see there is highly selected, and consists largely of children with whom simpler methods have consistently failed

TABLE I—AGE GROUPS OF PRESENT *OFFENCES*

Type of offence	Age (years)			Total
	8–11	12–14	15–17	
Marauding	20	30	15	65
Proving	1	6	18	25

Function of the Mental Hospital

THE section of psychiatry met on April 10, with Dr W D NICOL, the president, in the chair, to discuss the Changing Conception of the Function of the Mental Hospital

Dr A R MAY outlined the changing pattern of psychiatric treatment by comparing two groups of patients admitted to Netherne Hospital in two three-year periods, 1935–37 and 1945–48 He stressed that results must be assessed against the changing background due to altered attitudes to mental illness as a whole In the hospital this was shown by the number of patients on parole, which was 5% in 1932 and 60% in 1955 Outside the hospital the running of outpatient clinics by hospital staff resulted in the admission of earlier and milder cases with a correspondingly better prognosis

The use of different physical methods of treatment had varied since their introduction on a large scale in 1942 Thus patients treated by prolonged narcosis numbered 175 in 1945, but only 19 in 1955 The number of patients receiving electroconvulsive therapy (E C T) rose from 380 in 1942 to 1216 out of 1900 patients in 1955 50 leucotomy operations were performed in 1942, 79 in 1949, and 19 in 1955 Deep insulin treatment was used in 133 patients in 1951, but in only 95 in 1955 In 1955 the number of patients receiving paraldehyde averaged 122, and sodium amylobarbitone 106, and there had been a sharp increase in the use of chlorpromazine

The method of sampling was chosen to produce numerically comparable groups for the two three year periods every other consecutive male and female admission was used in the period 1935–37, and every sixth admission in the second period covering 1945–48 600 cases fell into each of the two sample groups, and a comparison was made between patients with schizophrenia or affective psychosis treated without (sample 1) and treated with (sample 2) physical treatments Five-year follow-up was achieved in about 80% In sample 1 there were 173 schizophrenics and 120 with affective psychosis, in sample 2 the figures were 125 and 83 Although the total death-rate fell, deaths due to exhaustion and suicide remained fairly constant

The number of symptoms among patients with schizophrenia and affective disorders was significantly higher in sample 1 36 4% of schizophrenics were hallucinated, compared with only 14 4% of sample 2 Among patients with affective disorders there were major symptoms in addition to depression or mania in 62 5% of sample 1, but only 45 7% of sample 2 These figures suggested that the increase in admissions during the second period was largely due to the admission of milder cases

Hallucinated and non-hallucinated schizophrenics and complicated and uncomplicated affective states were examined separately Among hallucinated schizophrenics there were no significant differences in improvement or recovery-rate between sample 1 and sample 2 Among non-hallucinated schizophrenics significantly more patients in sample 2 were at home after one and five years, although among these too the proportion of recoveries remained about the same The evidence suggested that physical methods of treatment had increased the number of patients discharged and reduced the total time spent in hospital, without however increasing the proportion of recoveries

Among patients with affective psychoses, those with more than one main symptom showed significant improvement in the treated sample on all items of comparison Here the greatly increased discharge and recovery rates might be attributed to the advent of physical treatments, which however did not materially improve the prognosis of patients whose only main symptom was either depression or mania

Dr MAY concluded that physical treatments appeared to have a pronounced effect in certain cases of schizophrenia and affective disorders, but results should be evaluated in relation to parallel improvement in the therapeutic atmosphere of the hospital There was no definite evidence as to which factor was causal and which consequential, but together these constituted the significant alteration in the pattern of care of the psychiatric patient during the past twenty years

Mr M S FOLKARD gave an account of a sociological investigation into the origin, prevention, and treatment of aggressive behaviour in a ward of 50 disturbed female patients

While the investigation was being conducted in the early part of 1955, considerable changes were taking place in therapeutic policy and ward organisation Patients were increasingly engaged in occupational and social activities, and more attention was given to individual patients, more liberal procedures were introduced for deviant behaviour previously controlled by rigid discipline and frequent sedation and E C T Ten weeks were spent making observations on the ward, the rôle of a relatively non-participant observer could not be maintained because the observer's presence itself tended to improve patients' behaviour

During the investigation two hundred and ninety eight acts of aggression were committed by 32 patients, a hundred and five of these created only a mild disturbance Statistical analysis showed that poorer cooperation with nursing staff and lack of parole were characteristics associated with aggressive patients Of 14 very aggressive patients 12 were unmarried, a higher proportion of patients who had been in hospital six or more years were aggressive There were more good workers among non aggressive patients, perhaps because employment provided an outlet Of 15 patients who had been leucotomised, 7 were still fairly aggressive and 5 very aggressive Of 23 patients who had received up to fifty electrical treatments 12 were aggressive, compared with 20 out of 27 who had received more than fifty treatments, suggesting that electrical treatment played no part in its prevention More acts of aggression occurred at meal times than in any other single situation

Ninety-one aggressive acts were related to patient-staff interaction, where personality differences among the staff were found to be important factors Eighty-eight aggressive acts arose from patient-patient interaction, mostly related to food, drink, sweets, and cigarettes, and response to interference and abuse A hundred and eighty aggressive acts lasted less than ten minutes, eighty-seven lasted between ten minutes and an hour, and thirty-one more than a hour

TABLE VI—TYPE OF THEFT AND SOCIO-ECONOMIC LEVEL ACCORDING TO FATHER'S WORK

Types of offence	Professional and skilled	Semi-skilled	Unskilled	Institution	Total
Marauding	12	18	35	0	65
Proving	10	8	6	1	25
Comforting	12	20	19	2	53
Secondary	3	7	8	4	22
Other	7	11	16	1	35
Total	44	64	84	8	200

$\chi^2 = 25.34$ n = 12 P < 0.015

in the upper levels, while marauding thefts tend to occur in the lower levels. The association between economic level and proving thefts is largely due to the fact that car-stealing is commoner in boys from upper levels (Wattenberg and Balistrieri 1952). The link between marauding stealing and underprivileged areas confirms observations of many writers (Mays 1954) that this type of offence is normal behaviour in boys of that class.

Study of physical condition, height, and weight did not yield clear-cut information, though there were hints that marauders have a high proportion of short boys.

The statistical findings were elaborated by study of boys making up each type. Most of those in the comforting group were obviously unhappy, but a distinction appeared between the two subtypes: the parents of those who stole from home seemed to be actively hostile, whereas the parents of those who stole impulsively and alone, from outside the home, were, although rejecting, casual in their attitude. In this latter group there were also three mothers whose earlier good relationship with the boy had been disturbed by illness and several parents who partially rejected the boy after the birth of a sibling.

The secondary stealers showed a family background of emotional instability and insecurity, and over a third of them had a sharp sense of grievance. They were impulsive and immature.

The background of the provers showed psychosexual difficulties usually due to a possessive, over-protective mother. The subtype which was originally placed in this group—the boys who committed breaking and entering offences alone—was found to be composed mainly of severely disturbed boys with no common problem.

No follow-up study was undertaken, but earlier studies based on similar concepts (Healy and Bronner 1939, Glueck and Glueck 1940) show that most young offenders reform. It seems likely that comforters, who begin early in life, continue to steal, whereas marauders give it up early in adolescence. Provers, who begin in adolescence, continue until early adult life. All this would be expected from the emotional drives which give rise to the offences. The secondary stealers are apparently rejected boys grown up, and they form the bulk of adult criminals. But to describe them as "typical" young delinquents is incorrect, for they are in the minority among juvenile delinquents.

Delinquents should not be thought of as a homogeneous group, and the present findings suggest inferences about the motivations which should be a guide towards treatment. Ideally, every offender should have treatment bespoke to his own requirements, but this is seldom practicable, and magistrates or others have to make a broad decision based on general impressions. With this in view I should suggest that boys who commit comforting offences need affection and not further deprivation, for this is probably the cause of the theft. Proving offenders are humiliated and unsure of themselves: they need reassurance and not further authoritarianism. Marauders, on the other hand, seem to be psychologically normal. They need alternative outlets for their drive and gang tendencies.

Summary

A statistical and clinical study of 200 young
thieves shows a firm association between pare
rejection and stealing from home, and a more cor
relation between unhappiness and impulsive soli
pilfering away from home. Boys who have been separ
from their parents early tend to commit these typ
offence.

Gang depredations begin in the prepubertal years a
are not associated with any clear pathogenic pare
attitude, but with a lower socio-economic background

Stealing, involving any form of bravado, such as th
of motor vehicles, is associated with adolescence. T
boy usually has a protective and affectionate mot
and an authoritarian father.

The rejected child has a poor prognosis and is lik
to become more deliberate in his offences. The oth
tend to reform, but their delinquent years cover so
what different age ranges.

Broad lines of treatment based on these findings a
suggested.

I carried out this research, under the supervision of Pr
A J Lewis, as part of the requirements for the PH D Lo

ADDICTION TO METHYLATED SPIRIT

ALLAN A MACDOUGALL
M A Glasg, L R C P E
MEDICAL OFFICER IN CHARGE OF ADDICTION UNIT

KENNETH MACAULAY
R G N, R M N
TUTOR, SCHOOL OF NURSING

GARTLOCH HOSPITAL, GLASGOW

THE special feature of the addiction dealt with he
is that the addicts drink products usually regarded
undrinkable.

Methylated spirit and surgical spirit, of which meth
lated spirit is the main constituent, are the more co
monly used "beverages" of these drinkers. Ma
however, develop skill in recovering methylated sp
from various commercial products. Thus boot pol
shellac, paints, and liquid brass polish have been t
sources for our patients. The brass polish is sometim
taken neat. Two of our patients report having consum
embalming-spirit.

All our patients addicted to methylated spirit h
been people whose original preference was for the usu
alcoholic drinks presumed to contain only ethyl alcohol
(ethanol), and they began to drink methylated spirit for
an exclusively economic reason.

Addiction to alcohol is always to ethyl alcohol, never
to methyl alcohol or the higher alcohols—amyl, butyl

ndesirable. It has not yet been used for epistaxis in dults since a suitable occasion has not arisen but its eliability in children is sufficiently encouraging to ustify trial in older patients

The balloon, made from latex rubber, has a capacity f about 30 ml, and is inflated by means of a fine tube ome 7 in long running to a standard 'Record' syringe nount The balloon is kept blown up by fitting a small ubber cap over the mount The introducer is basically a $8^1/_2$-in stainless-steel tube open on one side with a ring andle near the proximal end One end has a narrow rough in which the stretched tip of the balloon can be etained The other has a similar notch to grip the balloon tubing (fig 1) To assemble for use, the tip of the balloon is stretched until it slips into the trough, where it is held by virtue of its own expansion when the tension is released. The deflated balloon and tube are laid in the body of the introducer, the latter being retained in position by the notch provided (fig 2)

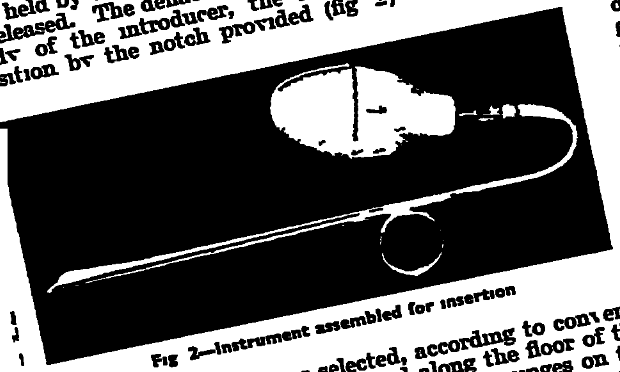

Fig 2—Instrument assembled for insertion

Either nasal passage is selected, according to convenience, and the introducer is passed along the floor of the nose, close to the septum, until the tip impinges on the posterior wall of the nasopharynx When the ring of the introducer lies vertically downwards the balloon will face the roof of the postnasal space and is inflated by a steady, single, complete squeeze of the 20-ml rubber ball fig 3) The tube may be kinked while a cross-action spring-clip is temporarily applied to prevent escape of air While steady traction is exerted on the tube the introducer, which has hitherto prevented the balloon slipping downwards into the oropharynx is withdrawn from the nose The tube is then strapped to the opposite cheek, still under slight tension, across the fulcrum of the columella, and the spring-clip, if desired, may be discarded after the nozzle of the tube has been occluded by a rubber cap Removal of the balloon is easily effected by allowing it to deflate

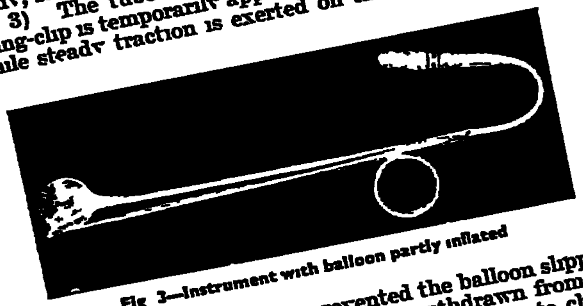

Fig 3—Instrument with balloon partly inflated

20 ml has proved a satisfactory amount of air for the balloon in children under 12 years of age In adults 30 ml would probably suffice, and a 30-ml bulb may be included in the outfit In all 11 cases introduction and emoval have been tolerated with little protest and have aused no difficulty to house-surgeons The balloon has generally been left in overnight and no ill effect, such as otitis media, has ensued

The apparatus, obtainable from Messrs Down Bros and Mayer & Phelps Ltd may be conveniently sealed in an airtight tin, together with a formalin tablet, the balloon having been dusted with glove-powder and wrapped in lint Before use the balloon and introducer may be rinsed in normal saline

Reviews of Books

Biology of Senescence

ALEX COMFORT, M B Camb London Routledge & Kegan Paul 1956 Pp 257 25s

ATTEMPTS to explain the process of senescence have never passed the stage of multiple hypotheses, and this, as Dr Comfort shows, is first because the basic facts are not known even of the distribution of senescence in animal populations, or of its dependence upon growth, reproductive activity, or ecology Secondly we may have been looking for the wrong thing for it seems very probable that there is no single factor, hormonal or other, whose presence or absence determines senescence

Senescence is a potential part of the life-cycle of many vertebrates, though it is rarely reached in the wild state, but some fish seem to show no evidence of it, and it may be, as Bidder thought, related to the migration of vertebrates to dry land, when a specific size, and therefore cessation of growth, became a factor in the survival of swiftly moving animals It is perhaps only because of the development of speech and the social habits of man that he has come to live commonly into the senescent period, for in a primitive social community a few elder statesmen who form the teachers, judges, and historians of the group are advantageous—perhaps more so than in our present society of small family groups—and may thus escape the pressure of selection in the post reproductive age

Dr Comfort discusses all these questions and many more He does not claim to answer the fascinating questions that he asks, but leans towards the view that 'many organisms are provided by evolutionary selection with a 'programme' of development and function which is directional and finite" As the programme runs out, the organism develops "a continuously self-aggravating disequilibrium" and mechanisms of homœostasis begin to fail Although he concludes that "all theories of senescence are at present based on unwarrantable assumptions in the absence of concrete answers to essential questions of fact," this does not preclude an interesting discussion of the manner in which the period of adult vigour might be prolonged and senility postponed in man, and on the ways in which further biological research might be directed towards relieving some of the present ignorance Although enlivened by some attractive similes and concepts and an occasional quotation from Belloc's lighter poetry, this is a serious work and not easy to read but those who are interested will find it rewarding, and it should be intelligible to any doctor, even if he has forgotten much of his early biological training This book also contains an assemblage of biological facts and references which must be of unique importance to serious students of the subject

Veterinary Parasitology

GEOFFREY LAPAGE M D M SC late lecturer in animal pathology and pathologist to the Institute of Animal Pathology University of Cambridge Edinburgh Oliver & Boyd 1956 Pp 964 £3 3s

THE control of parasitic infections in farm stock has received increasing attention in recent years but it would be difficult to find a book in the English language which covers the subject in such an authoritative and comprehensive way as does this

Dr Lapage s book is divided into four parts which embrace a study of the Nemahelminthes Platyhelminthes Arthropoda, and Protozoa and he has given a zoological description of the phyla to which the various species belong This is followed by detailed consideration of the individual species including its life history effects on its hosts symptoms of disease that may be caused and treatment and methods of control There is little in the subject matter which calls for criticism In his excellent description of liver fluke disease Dr Lapage remarks that acute liver rot may possibly be commoner in sheep than is generally supposed—a statement with which those who have examined numbers of sheep livers in slaughterhouses will fully agree In dealing with the life history of *Tænia saginata* he might have mentioned the observation of Götzsche, Silverman, and others that seagulls may be responsible for of this hospital and that addicts to alcohol now form a majority of our male admissions from July 1, 1954, to June 30, 1955, 199 addicts to alcohol were admitted in the total of 320 male admissions

Case-reports

At the time of writing our inpatients include 8 drinkers of methylated spirit (all males) We append some points from the histories of each All are voluntary patients except case 2

CASE 1—An unmarried labourer, aged 51, of no fixed abode, had been addicted to alcohol for 21 years and to methylated spirit for $19^1/_2$ years, and had 24 convictions for drunkenness He was quiet, well behaved, above average intelligence, sociable and a good worker in hospital, and had no psychotic features

CASE 2—A labourer, aged 37, lived with his wife and 6 children when not in hospital or in prison Addicted to alcohol for 13 years and to methylated spirit for 6 years Convictions 15 for drunkenness and 2 for breach of peace Usually quiet and pleasant but has periods of manic excitement, has been 15 months in hospital and is certified, good worker when well, of average intelligence, has escaped 3 times from hospital during present admission, was twice previously admitted here

CASE 3—A seaman, aged 49, married but separated from his wife and 1 child, of no fixed abode, has not worked since 1950, when right leg was amputated above knee, after accident while drunk Addicted to alcohol for 28 years, and methylated spirit for 26 years Convictions for drunkenness over 200 Euphoric, friendly, of average intelligence, since accident has status of cripple—i e, walks with crutches and not expected to work

CASE 4—An unmarried labourer, aged 44, of no fixed abode, addicted to alcohol for 23 years, and to methylated spirit for 9 years Convictions for drunkenness over 50 Quiet, solitary, of more than average intelligence, with good vocabulary, sensitive, pessimistic, well behaved in hospital, and works well but believes himself irrecoverable

CASE 5—An unmarried labourer, aged 30, a sporadic vagrant living for periods at his parents' home, addicted to alcohol for 8 years, and to methylated spirit for $2^1/_2$ years Convictions for drunkenness 7 Schizoid features prominent, shy, solitary, emotionally blunted, but hopeful and coöperative regarding treatment and recovery Intelligence above average, and good rapport exists but from intellectual acceptance more than emotional response

CASE 6—A married fireman, aged 47, of no fixed abode, separated from his wife and 2 children for 8 years Addicted to alcohol for 27 years and to methylated spirit for 11 years Convictions for drunkenness over 40 Has general paralysis of the insane well arrested by treatment, seems unimpaired intellectually and of average intelligence, an exemplary patient who works well in hospital and now has good prospect of being reconciled with wife and family

CASE 7—An unmarried tool setter, aged 41, of no fixed abode, addicted to alcohol for 16 years, and to methylated spirit for 5 months Convictions for drunkenness 4 Euphoric, extraverted, but with strong sense of shame at having become "depraved" drinker, coöperative and optimistic regarding prospects of recovery, sociable and works well in hospital

CASE 8—A miner, aged 58, married but childless and separated from his wife for 5 years, but visited by and reconciled with her since admission, lived as vagrant for 8 months before admission Addicted to alcohol for 31 years, and to methylated spirit for 3 years Convictions for drunkenness 23 A pleasant quiet man, who has worked very well in hospital as builder's labourer, is about to be discharged to live with wife and is felt to have good prospect of sustained recovery

Prognosis

We have only recently—i e, in the last year—come to believe that sustained recovery is possible in some of these cases 3 people at present, including our only female, have periods of 3–7 months' sobriety behind them and are working and keeping in touch with the A A organisation We believe that if we continue to work hopefully and sympathetically on these patients we can obtain as good results as with other addicts to alcohol

Treatment

The general principles of detoxication, sedation a rest in the early stages are observed as with other ad to alcohol Preparations of vitamin B complex w vitamin C and potassium bromide gr 60 b d are g in most cases because this salt can replace the l sodium chloride, and in addition has a sedative act- Depletion of sodium chloride from tissue fluids is bel to be the chief factor causing craving

A special feature in the physical treatment of addict methylated spirit is that disulfiram ('Antabuse') unsafe Despite the low content of methyl alcoh methylated spirit, if the spirit were taken in the disulfiram- sensitised patient, the chemical linkage might liberate a dangerous amount of formic acid in the blood

Individual psychotherapy and group therapy, provi by membership of Alcoholics Anonymous, together w hospital routine are the most valuable therap- weapons and used with enthusiasm, should recoveries

Summary

Addiction to methylated spirit and its derivatives is a secondary or substitute addiction developing on the basis of an established addiction to ordinary form of ethyl alcohol

It is caused by poverty

Addicts to methylated spirit are more hopeful material than has been supposed for treatment and rehabilitation in hospital

We are grateful to Dr J W MacPherson for help and encouragement

In the Mental Hospital *

CHANGES OF SOCIAL ENVIRONMENT THEIR EFFECT ON MENTALLY DETERIORATED PATIENTS

A R MAY

M B Lond, D P M

ASSISTANT PSYCHIATRIST, RESEARCH DEPARTMENT, NETHERNE HOSPITAL, COULSDON, SURREY

Now that emphasis is placed on the desirability of treating psychiatric patients outside hospital whenever possible, we may expect the mental-hospital population to consist increasingly of patients whose illness is chronic and who are mentally deteriorated The likelihood that physical methods of treatment will do much for these patients is now discounted, and it is realised that any advance in their management must depend upon reorientation of the attitude of the staff, who must understand and accept the difficulties yet maintain their interest and enthusiasm Apathy among the staff is a factor which must be acknowledged and faced if the problem is to be tackled at all

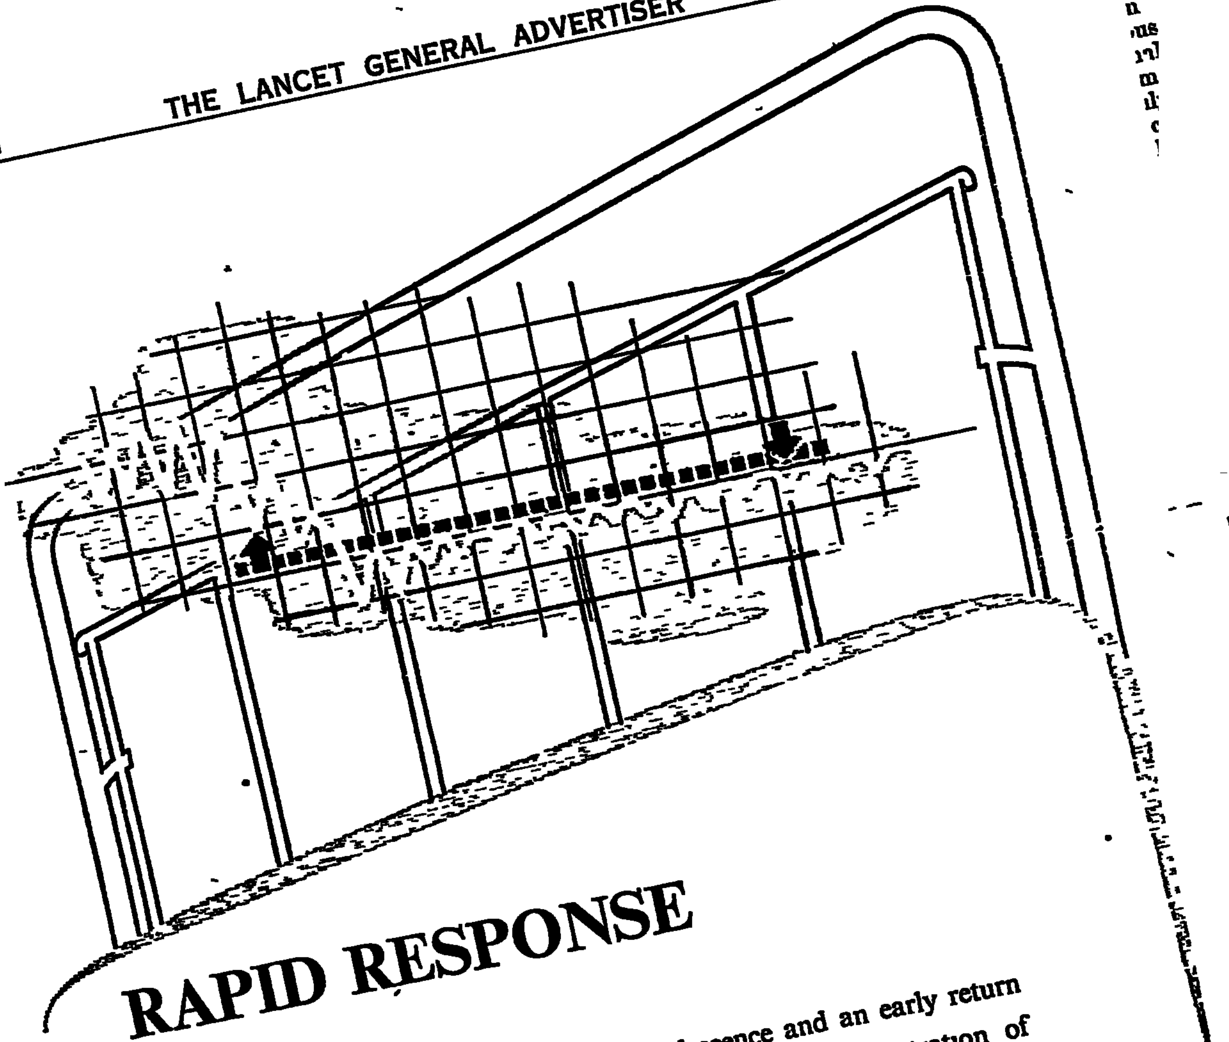
In this article I shall describe how such a change of attitude influenced the behaviour of a ward of chronic deteriorated patients

THE BACKGROUND

The Patients—The ward was a closed male ward holding up to 70 patients (never less than 65) To it were sent all the most deteriorated patients in the hospital and there was no significant change in the characteristics of those admitted during our investigation (January

---

* A group of articles chiefly concerned with the value of active occupation and work for mental patients, and the means whereby it is best provided



RAPID RESPONSE

Rapid response to treatment, smooth convalescence and an early return to normal activities is a natural result of the oral administration of Chloromycetin* Readily absorbed from the gastro-intestinal tract, Chloromycetin diffuses rapidly and penetrates tissue barriers easily, producing blood-levels which rise proportionally with increase in dosage

Chloromycetin

the original Chloramphenicol

no similar ward that could be used as an independent control Many of the patients shown as ward workers in the records of 1954 did in fact do no more than sit about in the ward

DISCUSSION

Assessment of behavioural changes is difficult despite the introduction of Behaviour Rating Scales[1,2] One cannot measure directly the difference in the staff's attitude, or the change in the social environment or atmosphere of the ward Nevertheless the evolution of a group attitude brings with it alterations in activity, which can be measured or counted, and table II is good evidence of increased cooperation and tolerance among staff and patients alike

Instances of improvement in individual patients are numerous At least 10 patients who were formerly mute and solitary have become spontaneous both in expressing their wishes and in offering to work The number of those unable to converse rationally has fallen from around 40 to 20 Over 50 patients now attend the social functions in the main hall, compared with 20 in January, 1955 The interest taken by staff in patients is now obvious and it is a matter of pride when a patient begins to show increased social awareness

The nursing staff as a whole has become conscious of a change for the better Junior nurses now look forward to working on the ward, and several have asked for a further period of duty there From being a source of embarrassment, the ward is now considered suitable for inclusion in any visitors' itinerary of the hospital

All members of the ward staff have been encouraged by the response to their efforts They see the problem in a more realistic light, and have proved for themselves that given a therapeutic atmosphere even the most deteriorated patient is capable of some improvement This is no new discovery, but the sense of achievement that has accompanied its verification has had a profound effect on morale

My thanks are due to Dr R K Freudenberg for his encouragement and advice, to Dr J P S Robertson for his help and criticism, to Mr J N Long for his loyal support, and to Charge Nurse R Brass and Charge Nurse W Neary, who so clearly saw what was wanted

Symposia

HYPOTENSIVE DRUGS

A SYMPOSIUM on hypotensive drugs and the control of vascular tone in hypertension was held under the auspices of the Biological Council on April 5 and 6 at the Wellcome Building, London A gathering of about 250 chemists, biochemists, physiologists, pharmacologists, and clinicians attended The speakers included several well-known visitors from abroad

Chemical and Biochemical Aspects

Dr H R **Ing** (Oxford) dealt with the structure-activity relationships of the veratrum and rauwolfia alkaloids, of the hydrallazine group, anti-adrenaline drugs, and of ganglion-blocking agents Certain simple amidines share with the veratrum alkaloids the property of a reflex fall of blood-pressure by stimulating afferent endings in the heart and lungs He suggested that 'Dibenyline' and its congeners were reversibly adsorbed at particular sites before irreversible combination with tissue constituents occurred—a view supported by the enhancement of activity in phentolamine, which contained the phenoxyethyl group, characteristic of reversible anti-adrenaline drugs such as piperoxan He pointed out that replacement of the three methyl groups attached to the nitrogen in mono quaternary ganglion stimulators by larger alkyl radicals invariably converted the molecule into a pure blocking agent, and he suggested that the more powerful the stimulating action of the original compound, the more potent would be the blocking action obtained by this replacement Dr Ing thought that a promising field for future research would be the study of tertiary bases as ganglion-blocking agents since, unlike the quaternary drugs (hexamethonium, pentolinium, &c), they would be readily absorbed after oral administration He cited 'Mecamylamine,' a secondary base, and two tertiary bases as examples of purely blocking agents He also stressed the need to study the selective activity of blocking agents on sympathetic and parasympathetic ganglia Examples of drugs which blocked parasympathetic ganglia preferentially were known—for example, 'Elvetil'—and he thought that drugs blocking sympathetic ganglia preferentially might be discovered

Mr J W **Billinghurst** (Beckenham) said that from over a hundred compounds that he had synthesised, two did appear to have some preferential blocking effect, they were diquaternaryamino benzhydryl compounds Their pharmacology was described by Mr A F **Green** (Beckenham) They have a ganglion blocking effect resembling that of the methonium compounds but they have the advantage of greater potency, greater selectivity, and much longer action This was confirmed clinically by Dr S **Locket** (Romford) who had tested them on about 60 patients They were potent hypotensive agents, producing when given subcutaneously in a dose of 5–20 mg a satisfactory lowering of blood pressure that lasted all day Dry mouth, constipation, ocular changes, and postural hypotension seldom caused any trouble They were absorbed orally, although the dose needed to be higher than the subcutaneous one

Dr H **Blaschko** (Oxford) distinguished between hypotensive drugs which interfered with the reaction between receptors and hormones (or neurohormones) and those which altered the amount of active hormone available to the receptors The first group included blocking agents The second group interfered with biosynthesis, release, or inactivation He regarded dopamine dehydrogenase, a newly discovered enzyme which forms noradrenaline, as the catalyst of the rate limiting step in pressor amine formation Amine *oxidase* might regulate noradrenaline formation by removing excess dopamine

THE LANCET
LONDON SATURDAY, APRIL 21, 1956

Cancer Cytology

Incredulity has delayed the development of exfoliative cytology in this country Many people have felt that the method must be one of hit and miss, for how can one be sure that a malignant cell will conveniently present itself at the moment and site at which a sample is taken ? Indeed how can the malignant cell be recognised with certainty as it lies alone, shorn of its recognisable surroundings ? It is also argued that where a growth is so accessible that there is a reasonable chance of obtaining an exfoliated cell, biopsy may be undertaken with more certain results it seems better to scrape the uterus than to take a smear from the vagina or cervix Wilcox et al[1] who "screened" 9815 patients for uterine or cervical growth by means of routine smears, found, out of a total of 233 cases of cancer, 33 in which suspicions raised by cytology were confirmed by clinical review and in 17 of these detection was possible only by cytology False positives bedevil results, and they affected 7% of the findings recorded by Wilcox et al Guerriero[2] found much the same proportion of misleading results, and eroded and infected cervices were the commonest source of a false positive Sometimes the hyperplastic changes in cells from the pregnant cervix simulated carcinoma For these reasons Guerriero recommended biopsy for the abnormal cervix, cytology being reserved for the apparently normal McDonald et al[2] would prefer to restrict uterine cytology to the detection of cancer in situ

Diagnostic cytology supplies only circumstantial evidence which must be weighed with other factors If the malignant cell can be caught just a little more than occasionally, then cytology's greatest application will be to those remote sites inaccessible to biopsy For example, bronchial washings examined by Clerf and Herbut[3] revealed malignant cells in 88% of 540 patients with growth in the lung, whereas biopsy was positive in only 31% of the same group There are, however, dangers in the procedure at this particular site biopsy may be impossible, and once suspicions are aroused by cytology thoracotomy may be the only means of further investigation It would be unfortunate if a major operation was undertaken on the evidence of a false positive Moreover, it may be impossible to determine from a positive result where the primary tumour lies, and a metastasis can pass as a primary lesion while the real source remains undetected, thus leading to an unnecessary thoracotomy and resection On the other hand, the work of Foot[4] is promising He examined smears from pleural, peritoneal, and pericardial effusions due to metastatic deposits, by studying the number of cells, their nuclei and cytoplasm, and their arrangement into "proliferation spheres," he was able to classify the primary site of the tumour correctly in approximately 70% of samples for mammary, bronchial, and gastric carcinoma Diagnosis of ovarian lesions proved elusive and reduced the over-all accuracy to roughly 50% Nevertheless, increasing experience on these lines might make it possible to identify the primary lesion from bronchial washings

The colon is another site where cytology might be a great help, though the important cells are sometimes out of reach Wisseman et al[5] and Bader and Papanicolaou[6] have shown that diagnosis by this method is feasible when the lesion lies in or distal to the descending colon Fæcal detritus is an obvious hindrance which can be eliminated only by preliminary purgation and enemata The method of collection is again by washings rather than by direct smears from secretions Rubin et al[7] have shown that cytology can determine the significance of a filling defect seen on barium enema which may be either a Crohn s lesion, diverticulitis, or carcinoma Galambos and Klayman[8] have had similar experiences, moreover, their negative findings were significant for cancer was ultimately excluded in 32 patients with colonic symptoms, though in 5 a radiological diagnosis of cancer had been made Cytological examination showed no malignant cells in any of the 32 Having had no false positives, they state categorically that the presence of malignant cells is conclusive evidence of a malignant lesion, and from their positive results in 26 patients they were even able to diagnose correctly a metastatic ovarian deposit Cytology would have special application in ulcerative colitis since malignant change may be hard to detect either clinically or radiologically, a positive cytological report in the long-standing case would tip the scale in favour of surgery despite the absence of other indications of malignancy—and carcinomatous degeneration in this disease is by no means inevitably fatal if taken early There is, however, one difficulty for the diagnostic cytologist in this disease, since large columnar cells are sometimes seen which simulate certain types of malignant cells The presence of undifferentiated malignant cells, however, may, according to Galambos et al,[9] be regarded as reliable evidence of cancer Galambos and his co-workers also indicate that these large columnar cells are worth further study because of their similarity to the large gastric cells of addisonian anæmia, which like ulcerative colitis carries an increased incidence of malignant degeneration Could these cells therefore represent a metaplastic reflection of the malignancy to come ?

Though diagnostic cytology is a difficult and time-consuming method requiring an expert hand, it must eventually become widely used in this country It may be confined, however, to centres where smears, properly obtained and fixed, may be sent for scanning by trained technicians under the supervision of a pathologist The subject is still in the exploratory

Dr G A **Perera** (New York) was not so optimistic as the two previous speakers He described his personal experience in evaluation of hypotensive drugs In his view the rauwolfia alkaloids not only failed to produce an adequate fall in blood-pressure in many patients, but were also liable to produce mental depression He had not found the veratrum alkaloids of any value whatever unless pushed to the limit, when they produced nausea and vomiting Hydrallazine modified the blood-pressure only slightly and needed to be combined with other drugs Pentolinium lowered the blood-pressure to normal or near normal, but was without effect on the renal complications of hypertension In the malignant phase of hypertension symptoms were ameliorated, retinopathy improved, and congestive failure relieved more consistently than by rest or sedation Side-effects and difficulties of regulation had prevented Dr Perera and his colleagues from using the ganglion blocking drugs successfully in patients with advanced disease except those who were cooperative Administration of hypotensive drugs was not justified in uncomplicated hypertension without symptoms The results obtained with any drugs in the treatment of hypertension were suppressive and not curative

The results of trials with combinations of hypotensive agents in Sweden were described by Dr B **Hood** (Gothenburg) He stressed that a high proportion of hypertensive patients were admitted to hospital in too advanced a stage of their disease for effective treatment to be possible In a series of 66 adequately treated patients with hypertension in grades IV (malignant) and III, 11 were dead and 55 living, 36 of them working full time Dr Hood said that at present he used oral pentolinium, combined with one of the rauwolfia alkaloids and also hydrallazine In his view the use of this triple combination was a considerable advance on sympathectomy

Prof C **Bartorelli** (Milan) gave an account of his experience with hexamethonium and reserpine in hypertension He also described experiments with the ganglion-blocking agent, ecolid, this was found to increase greatly the blood flow to the lower limbs but not the upper limbs

In the discussion Dr E L **McDonald** said that he gave anticoagulants before hypotensive drugs to diminish the risk of thrombo-embolic phenomena which might result from a fall in blood-pressure

Dr R W D **Turner** (Edinburgh) deprecated the use of hypotensive drugs in symptom-free patients. He said that the lives of patients with symptomless hypertension were being made miserable by the administration of potent drugs

In reply to a question Professor **McMichael** said that the chance of the malignant form developing in a patient with hypertension was about 1 in 200

Control of Vascular Tone in Hypertension

Prof **Clifford Wilson** said that the clinical and pathological features of established hypertension were the same whether or not there was a manifest cause such as phæochromocytoma or renal disease In the malignant phase of hypertension there was a qualitative change in vascular behaviour—namely, regional vasoconstriction followed by paralytic vasodilatation This might be the cause of fibrinoid necrosis of the arterioles

Dr M A **Floyer** and Dr J M **Ledingham** showed that both renal and extrarenal factors were involved in experimental hypertension in rats The extrarenal factor was probably of adrenal origin and could be neutralised by the normal kidney Changes in intracellular and extracellular electrolytes accompanied the experimental procedures These were difficult to interpret, but possibly they might affect the reactivity of the arteriolar muscle

Dr B **Folkow** (Gothenburg) produced evidence t the resistance of the limb vessels in full ischaemia d tion was raised in hypertensive patients He sugg that this might be due to some structural change, a pointed out that mild thickening of the arteriolar would greatly shift the range of resistance over wh nervous and humoral control could operate

Dr J **Conway** demonstrated that the barore reflexes of hypertensive rabbits were fully active stabilising the blood-pressure at its abnormal level. H thought that the logical use of ganglion blocking dr was as adjuvants to direct vasodilators

Prof C **Heymans** (Ghent) said that the barorecep reflexes could be set to new levels by local action o vasoactive substances on the carotid sinus

Dr J H **Green** showed records from the carotid se nerves in hypertensive dogs which confirmed that th resetting of the reflexes took place on the affer side

Dr R S **Duff** said that hypertensive patients had, o the average, a normal hand blood flow Their ves were, however, more than normally sensitive to adren line, though not to noradrenaline Patients treated with ganglion-blocking drugs became hypersensitive to noradrenaline as well

Dr **Peart** described work indicating that the increased vascular resistance in the hands of hypertensive patient persisted after inhibition of sympathetic constrictor tone

In winding up the discussion, Professor **Wilson** said that the regularity with which experimental hypertension was reversible argued against structural changes in the arterioles being important in its maintenance He had suggested that persistence of hypertension after removal of a clipped kidney was due to hypertensive lesions in the remaining kidney, but he did not think that the functional abnormality could be closely correlated with histological changes On the whole he thought the rat experiments provided some close analogies with hypertensive disease in man, but he welcomed the increasing amount of work on the vascular responses of hypertensive patients The discussion had shown that there was at the moment less interest than formerly in the search for circulating vasoconstrictors as the cause of hypertension, and greater emphasis on the local conditions affecting arteriolar reactivity

ound that the infectivity of their nucleic-acid preparation was unstable, and was abolished by treatment with ribonuclease It is possible that some of the infectivity of the reconstituted virus prepared by FRAENKEL-CONRAT may have been due to the nucleic acid present, the protein acting mainly as a stabilising factor, further experiments will be required to settle this point

We have become familiar with the fact that pure preparations of desoxyribonucleic acid can, under certain conditions, transform pneumococci and other organisms into the serological variety of organism from which the nucleic acid was derived Now comes the idea that a ribonucleic acid alone can induce an infected cell to produce intact virus particles More and more problems in biology seem to be gravitating towards the chemistry of the nucleic acids

The Indian Village

IF today we seem to hear less about the theory of preventive medicine, this is partly because, in so many parts of the world, theory has passed into practice Under the auspices of the United Nations, of governments, of philanthropic foundations, and of private agencies, schemes which a few years ago would have seemed visionary have brought together teams of medical and other experts for joint action against poverty and disease

Of such schemes, one of the most interesting is the Indian Community Development Project, described by Mr T SWAMINATHAN, of the Indian Civil Service, at the Conference on Regional Planning and Development held in London last September This project, started in 1952 under the Indian government's first five-year plan, is intended eventually to raise the standards of living of a population of no fewer than 310 million, most of whom have hitherto existed at subsistence level Naturally its achievement must take many years, but the progress already made shows with what energy and foresight the Indian leaders are tackling some of their problems In this they owe much to Mahatma GANDHI, and it is because he saw clearly the limitations of welfare schemes imposed from above that the I C D P is primarily a movement to enlist the cooperation of the people in their own betterment the government, through its central agencies, supplies the means, but the momentum is to be supplied by the villagers, working through their village organisations During the British tenure of India the peasants got the benefit of sound systems of justice and taxation, and a skeletal rural medical service, but otherwise no great effort had been made for their social advancement indeed, the policy was, on the whole, to tamper with rural institutions as little as possible Only now, therefore, is the village population (83% of the total) beginning really to emerge from the two or three millennia during which its intricate customs and beliefs seem to have changed very little So far new ideas have not made much impact, though bicycles, cinemas, sewing-machines, and alarm clocks have been fully accepted by those few who have means to enjoy them But the government of free India, activated by GANDHI, the threat of Communism, and universal franchise, has set to work to narrow the great gulf between itself and the overwhelming majority of its citizens

The programme began in 1952 with 55 " project areas," each consisting of 500 villages with a total population of about 200,000 These areas are divided into " development blocks " which cover about 100 villages and are themselves divided into " circles " containing 5–10 villages In each village there is a development council through which the villagers themselves operate the projects and seek the specialised help and advice they require Projects are planned in agriculture, communications, education, health, cottage industries and subsidiary employment housing, and social welfare the health projects centre mainly upon the protection of water supply, proper disposal of human and animal wastes, the control of epidemic diseases, and the provision of midwifery and medical services Such work demands complex administrative machinery, but the Indian scheme differs from many others in that this machinery revolves round the all-important " village-level worker,"—who, with the individual village councils is responsible for each circle This vital man has to cope with the forces of reaction as represented in almost every village by the big landowner, the money-lender, the priest, and even the council of elders, all of whom fear that the influx of new ideas and equipment may reduce their power and prestige (Perhaps no other institution anywhere is more truly conservative than the Indian Hindu village, where one self, one's children, and one's children's children forever, are destined to follow the narrow caste rules—working, marrying, and conforming in all respects, on pain of social excommunication) With the villagers' confidence and cooperation, the village-level worker can do great things without them he does nothing except deepen the villagers' inherent suspicion of " government " and all its representatives Hence one of the question marks behind this great effort is whether enough of the " right " men will be prepared to forsake the bright lights of the big city for the mud hut and humble fare of the village Medical workers, too, have always proved hard to attract to the countryside

Though the project is too big for detailed description, some idea of the scale is given by the fact that on the medical side alone the personnel requirements of the first five-year plan are 620 doctors, 2480 midwives, and 620 each of health visitors and sanitary inspectors—figures which, it is hoped, will be trebled in the second five-year plan The problems meeting these medical workers are great, for it is no medical vacuum into which they move, and they inevitably come into competition with the local " veds " or practitioners of the Ayurvedic system (which has given us rauwolfia among other things), to be found in most villages Their task is not made lighter by the (to most Western eyes) misguided government support to schools of Ayurvedic and homœopathic medicine To the average Indian, Western medicine (known as " allopathic ") is but one alternative of a number, to be considered if the " ved," " hakim," or " homœopath " fail to cure the condition quickly, with their very much cheaper medicines Public health measures also, are not made easier in circumstances where successful opposition can be made to B C G on the grounds that it means " Birth Control General "

Though the I C D P is primarily financed by the Indian government, the people's contribution is

Letters to the Editor

STAPHYLOCOCCAL ENTERITIS

SIR,—I have read with great interest the article by Dr Todd and Mr Hopps[1]

The two cases which they report under the title "staphylococcal enteritis" were actually pseudomembranous enterocolitis Although there is much resemblance in their clinical manifestations, pseudomembranous enterocolitis and staphylococcal enteritis apparently are two separate and distinct entities

The relationship between pseudomembranous enterocolitis, antibiotic therapy, and antibiotic resistant staphylococci is probably not causal but coincidental A review of the necropsy records at the Mayo Clinic showed that from 1927 to 1936, inclusive, when no antibiotics were used, 42 patients died of pseudomembranous enterocolitis, whereas from 1943 to 1952, inclusive, in the antibiotic era, only 37 patients died of pseudomembranous enterocolitis[2] In staphylococcal enteritis the enteric mucosa remains intact, whereas in pseudomembranous enterocolitis the mucosa is denuded In staphylococcal enteritis the early administration of an antibiotic effective against the staphylococci found in the stool usually leads to recovery Such therapy is usually ineffective in pseudomembranous enterocolitis

The pathogenesis of pseudomembranous enterocolitis is not clear It usually follows operations on the bowel, but has been seen in patients with bowel lesions who had not undergone operation, or who had an entirely different type of illness It is conceivable, in this antibiotic era, that some of these patients may also show resistant staphylococci in the stool The presence of these organisms in large numbers may aggravate the underlying pseudomembranous enterocolitis

Staphylococcal enteritis is a different pathological entity It appears that the victims of this complication either harbour or contract from carriers staphylococci which are resistant to the administered antibiotic agent These organisms then invade the intestinal tract, where an opposing normal flora has already been substantially suppressed by antibiotic therapy In the intestinal tract the staphylococci grow in pure culture and most probably produce a toxin which causes the gastro intestinal and systemic symptoms—namely, diarrhœa, vomiting, fever, confusion, shock, oliguria, and azotæmia Not all of these symptoms are necessarily present in every case In overwhelming toxæmia the patient may die in a few hours, even before the onset of diarrhœa Staphylococcal enteritis has followed the administration of various antibiotics, and has occurred in both surgical and non surgical patients, and in patients who received the drug orally or parenterally This entity may be treated successfully if (a) it is recognised early, (b) the offending antibiotic is immediately withdrawn, (c) this is replaced by erythromycin, and (d) the necessary supportive therapy (to maintain or restore fluid and electrolyte balance, blood pressure, &c) is instituted Today erythromycin is generally recommended as the antibiotic of choice in this situation However, sensitivity of the isolated pathogen should always be determined because of the possibility of an erythromycin resistant staphylococcal strain

Diarrhœa during a course of antibiotic is not always due to resistant staphylococci The mild diarrhœa without systemic reaction that so commonly arises during oral administration of the so called broad-spectrum antibiotics is probably produced by chemical irritation, sensitivity to the drug, or disturbed intestinal milieu Possibly in some such cases one may find an abundance of antibiotic-resistant staphylococci in the stool Mild diarrhœa without systemic symptoms will respond to the discontinuance of the offending antibiotic medication, without any further measures

ALLEN E HUSSAR

DEFICIENCY OF ESSENTIAL FATTY ACIDS

SIR,—After the gentle reprimand which Dr Sinclair has given me (April 7) for daring to comment on matters in which I have not worked experimentally, it is good to see that he himself has not hesitated to refer to the work of others In building his house, he has used as his cards some twenty-five reports of original work, in which he has himself been associated with four Of the diseases of which he speaks, his work has been on atherosclero not on carcinoma or leukæmia or peptic ulcer or disseminated sclerosis or any of the other parts of his "etcetera"

My purpose, however, is not merely to say *tu quoque* to Dr Sinclair It is to give one tiny warning to his readers, and one tiny suggestion to Dr Sinclair The warning is that the decorations on the edifice—terms like tetraenoic and trans fatty acid—are bright and glittering but they may well dazzle the eyes of those who are viewing it from the non-specialists' enclosure As a result, it may be that the cards look like real bricks and that the stability of the edifice is assumed to be much greater than it really is

The suggestion is that Dr Sinclair himself removes one of the crumpled cards in his foundation If his gentle hands remove it, they may inadvertently tumble down the whole pretty building, which at this stage does not perhaps deserve so cruel a fate I refer to the statement made by Dr Sinclair, and previously by Dr Nyrop that margarine is deficient in E F A Irrespective of any "unnatural" trans acids which margarine may contain and which *may* (according to Sinclair) act as "anti vitamins" for E F A, the plain fact is that margarine contains more E F A than butter *when tested biologically* That is to say, whatever the relative amounts of linoleic and *arachidonic acids*, or whether there are substances which may increase or decrease their potencies, the final result in the animal is that the substitution of margarine for butter in the diet increases the *effective* amount of E F A

I might add that in my previous letter[1] I referred to the work of Dr H J Deuel in which he had found that the biological E F A activity of margarine was some two to four times that of butter Since then, Dr Deuel has personally informed me that refinements in his methods of testing suggest that this is an underestimate, and that *margarine may have five times the amount of E.F.A or even more*

Truly the problem of the association of fatty acid deficiency with the conditions mentioned by Dr Sinclair requires a great deal more work It is for the future to show whether the resulting evidence becomes a strong wind which destroys his beautiful edifice, or a gentle breeze which settles it into a stable permanent structure

JOHN YUDKIN

THE BASE DEGREES BY WHICH WE RISE

SIR,—In his letter to Barbara (April 7) Dr "Peter Davey" (or could it be Professor Peter Davey ?) discusses the position of pathologists in regard to the lack of higher examinations and of a representative organisation. May I, as another private individual, comment ?

If I have appreciated the troubles of the clinical pathologists correctly, they are concerned because they do not know what advice to give to their registrars who ask which higher qualification should be sought Dr Peter Davey asks what purpose these exams serve and seems to dismiss them as unnecessary Unfortunately—and the more intelligent registrars in clinical pathology appear to have recognised this—hospital pathologists have to live in the same world as the rest of us and the competition for consultant posts is now becoming such that the young man (or his sister) without a higher qualification is likely to wait a very long time for an appointment He might be more successful, of course, in the less competitive field of university pathology It is becoming increasingly obvious that if hospital pathologists wish to keep the pay of consultants, they will have to fill their ranks with holders of higher qualifications, or their medical brethren in other specialties and the lay administrators will demote them—and this notwithstanding the truth that a good pathologist always acts as a consultants' consultant eported an inquiry into the analgesic action of a series f compounds in which the N-methyl group of pethidine s replaced by a tertiary amino alkyl group. Experi- nentally one of this series, morpholinoethylnorpethidine, s somewhere between three and seven times more potent han the parent substance, yet without equivalent increase n toxicity. This analgesic seems well worth further nvestigation, but experimental findings are not always substantiated in clinical practice. In 1949 a piperidyl analogue of iso amidone was found under experimental conditions in both animals and man to be less depressant to respiration than morphine, pethidine, and amidone[4 5] Clinical trial as an adjunct to nitrous oxide anæsthesia, however, now suggests that it is not a satisfactory substitute for pethidine because of the severe respiratory depression that it may cause, and there is also some doubt about the adequacy of analgesia[6]

PROTECTION AGAINST TETANUS

NDEPENDENCE Day celebrations in the United States ed to be responsible for many deaths from tetanus, at the use of tetanus antitoxin in the treatment of the juries reduced the number of deaths from 100 per 1000 njuries on Independence Day, 1903, to 3 deaths per 1000 n 1913. In the early months of the 1914–18 war not enough tetanus antitoxin was available, largely because the incidence of tetanus had been negligible on South African soil during the Boer war. The incidence of tetanus in 1914 was about 8 cases per 1000 wounded—a similar figure to that recorded during the Franco-Prussian war of 1870. But ample supplies of tetanus antitoxin were soon produced, and the incidence fell to 1 per 1000 wounded. Yet, despite the way in which antitetanus serum has been used more and more freely since those days, some 50 or more people still die from tetanus in this country each year. Most of these infections probably arise as the result of injuries so trivial that they are not seen by a doctor, so that the injured have no chance of protection by passive immunity. It seems therefore that this annual loss of life can be substantially reduced only by the wider use of active immunisation.

The protection afforded by tetanus antitoxin lasts only about two weeks, and in persons who have had antitoxin on a previous occasion it may be eliminated om the body abnormally rapidly and no appreciable rotection may be conferred. Fortunately, we can give much more lasting protection by active immunisation. Since whole armies can be immunised before facing considerable risks of injury, it is natural that much of our information about active immunisation should come from military sources[7] It is largely as the result of war experience that successful methods have been established. Two doses of tetanus toxoid, at an interval of six weeks, followed by a third dose six months later, confer adequate immunity for five years. Booster doses are best given every four years. After an injury a further dose of toxoid stimulates the defences sufficiently to make the administration of antitoxin unnecessary unless treatment has been delayed for more than twenty-four hours after injury[8] Both the British and United States armies used routine immunisation during the late war, and immunisation was compulsory for American soldiers. The incidence of tetanus was reduced to $^{1}/_{25}$ of the 1914–18 rate in the British Army, and among American troops there was only 1 case of tetanus among all battle casualties. Tetanus antitoxin was given to British wounded, but the Americans used no antitoxin, giving their injured a booster dose of tetanus toxoid. After a break from 1945 to 1949, active immunisation has been a routine procedure in the British Army, so that there is a section of the community—men who have done their National Service—with an adequate basal immunity. But the rest of the civilian population are poorly defended. Most deaths from tetanus occur in the 5–14 age group and there is therefore much to be said for immunising children when they go to school. Combined diphtheria-tetanus immunisation of children has been compulsory in France since 1940, and nearly all Danish children are similarly treated[9] In the United States and Canada diphtheria-tetanus immunisation, often combined with whooping-cough vaccination, is widespread. The child entering school at 5 might well receive a booster dose of diphtheria prophylactic combined with the initial dose of tetanus toxoid. But, since basic immunity to diphtheria will already have been established in many of these children, the secondary response to the diphtheria toxoid might well swamp the antigenic response to tetanus toxoid unless the composition of the combined prophylactic were suitable, so careful inquiry into the effect of various prophylactic combinations would be needed before such a scheme could be adopted.

It is not easy to envisage immunisation of the whole adult population, although those most at risk might well be offered protection. Agricultural workers, especially those in eastern and south western England, labourers, stable hands, and mechanics are all prone to injuries contaminated with earth. But so are pedestrians, cyclists, and drivers on our roads, and that includes almost everybody. Nevertheless, in a generation's time the toll of tetanus would be much reduced if expectant mothers and children entering school were added to National Servicemen as priority candidates for tetanus immunisation.

MENOPAUSAL PANNICULOSIS

A FEW years ago Copeman and his colleagues[10 11] gathered evidence to show that “the fat tissues of the body are subject to pathological variations which cause pain.” They were investigating the common syndromes of “fibrositis” and “rheumatic” pain, and they suggested that, in certain cases at least, the characteristic pain originates in areas of local œdema of the fibro fatty subcutaneous tissues, particularly in the residual fat areas of the back. Their post mortem dissections and biopsy studies of the back in fibrositis showed that the palpable painful nodules were often identifiable as œdematous fat lobules. Their view of the origin of the pain as a local tension œdema was supported by their finding that induction of a state of clinical dehydration (again in selected patients) brought relief of pain to a significant proportion. Copeman[10 12] has suggested a similar cause for the type of fibrositic pain that occurs in panniculitis, a condition frequent at the age of the menopause, in which the panniculus adiposus increases in bulk in certain characteristic regions of the limbs and back, producing pain and tenderness. He believes that also in this syndrome the underlying mechanism is a shift of extracellular fluid into the fatty tissue cells.

Baker[13] has recently studied panniculitis (she prefers the term “panniculosis”) by means of skin biopsies in 49 cases. The biopsies showed no apparent abnormality of the subcutaneous fat, apart from increased bulk, but 80% of them showed an increased depth and density of the collagen layer of the skin, though the fibres themselves were mature, acellular, and morphologically normal under

ELECTROPHORESIS OF PLASMA-PROTEINS

SIR,—Dr Gero and his colleagues (Dec 31) mention that their electrophoretic findings support the hypothesis that splitting of the β band may be caused by some change in the lipoprotein pattern of the serum

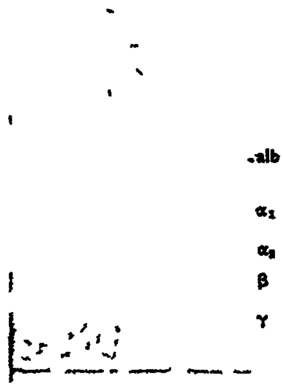

Fig 1—Example of 4-hour run

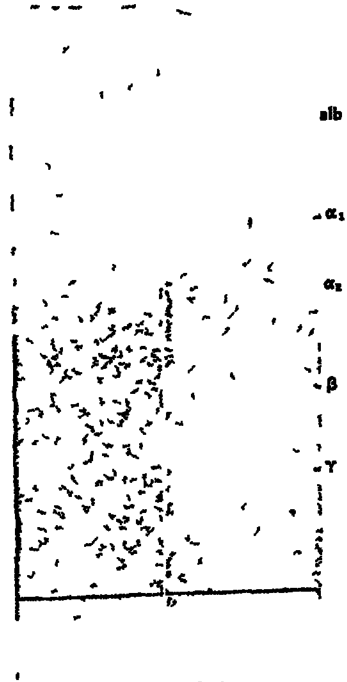

Fig 2—Example of 16-hour run

I was able to illustrate by paper electrophoresis the effect of heparin injection on lipoproteins After 24 hours' refrigeration at 0°C, fasting serum and serum taken 30 minutes after injection of 25 mg of heparin are added to one third part of homogenised and sterilised, undiluted milk The milky sera are then incubated at 37°C for $2^1/_2$ hours Next, 0 08 ml of each serum sample is brought upon a strip of filter paper with a median split and electrophoretically run for 16 hours using a barbitone buffer pH 8 6 After staining with sudan black, three features can be seen (*a*) In almost all paper-strips the right side (post heparin milky serum) is less stained than the left side (fasting milky serum), indicating a disappearance of lipids This corresponds with the clearing effect (*b*) Nearly all strips show a shift of the β globulin lipoprotein band towards the space between β and α_2 bands, sometimes even towards the α_1 and α_2 bands This occurs only on the right side of the strip (*c*) Sometimes a more or less clear band appears between the β and γ globulins, which suggests a splitting of the β globulin band into two components—namely a more rapid (see [*b*]) and a slower one This too is only seen on the right side of the strip

We are trying to ascertain whether this third feature appears only when the patient has symptoms of duodenal ulcer I could not demonstrate that atherosclerotic patients form an exceptional group in show features (*a*) and (*b*) It is noteworthy that feature (and (*b*) are also seen in a four hour run electrophor with smaller strips and 0 02 ml of serum The featu described here are shown in figs 1 and 2

HYDROCORTISONE IN SEVERE TETANUS

SIR,—Despite the introduction of potent antitox penicillin, various relaxants, general anæsthesia, tracheotomy, and intermittent positive pressure respirat in the management of tetanus, the problem of prevent death in severe cases is still unsolved We have shown controlled studies [1–3] that corticotrophin, oral cortiso, and oral hydrocortisone can effectively suppress the manifestations of severe tetanus in man, modifying the course and reducing the mortality Corticotrophin takes about 48 hours before exerting its full effe Injected cortisone suppresses pyrexia quite well b aggravates spasms and has an adverse effect on the whole We report here the results in five cases of severe tetanus treated with parenteral hydrocortisone

All five cases (see accompanying table) were "severe" according to the criteria previously laid down by us The patients were given hydrocortisone in addition to the bas therapy, which included antitoxin, penicillin, paraldehyde supportive measures, and wound hygiene Each of them received on admission an infusion of 50 mg hydrocortisone over about 4 hours (case 3 received two such infusions) Intramuscular injections of hydrocortisone suspension were started at the same time, 25–50 mg being administered every 6 hours at first If hormone was still required after 10 days the patient was switched to oral cortisone to conserve the supply of hydrocortisone The basic therapy, apart from hormones, was essentially the same as we applied in previous trials

DATA ON 5 CASES OF SEVERE TETANUS

Case no	Age (yr)	Sex	Mode of infection	Incubation period (days)	Period of onset (hr)
1	35	F	Dog bite of rt leg	6	48
2	12	M	Puncture by rusted nail of rt foot	5	36
3	10	M	Otorrhœa lt ear	6	24
4	40	*F*	*Furuncle of lt ear*	5	30
5	60	M	Puncture by thorn of lt foot	6	24

Case 2 died of circulatory failure 64 hours, and cases 3 and 5 died of respiratory failure 38 and 60 hours respectively, after admission

Cases 1 and 4 survived

CASE 1 needed hormones for 20 days, the dose was tapered off after 12 days Lockjaw was complete from the 2nd to the 4th day, improved gradually thereafter, and disappeared on the 25th day Spasms were frequent up to the 7th day and occasional up to the 13th day Paraldehyde requirements were only moderate The temperature, which fluctuated around 100°F, went above 101°F on four occasions in the first week and was normal on the 16th day Her stay was prolonged because in the 4th week, during convalescence, she developed pneumonia requiring additional streptomycin, and in the 5th week an abscess in her left thigh at the site of previous paraldehyde injections, requiring drainage We have occasionally seen such abscesses even in cases not treated by hormones, especially where some paraldehyde has got into the subcutaneous tissue In this case we do not think that the abscess was related to previous hormone therapy, because it developed long after the withdrawal of hormones

CASE 4 received hormones for 14 days, the dose being tapered off from the 6th day Trismus, which was never

MYASTHENIA GRAVIS

THE Myasthenia Gravis Foundation, established in New York in 1952, is a charity which collects funds for research into the disease Considerable sums have already been allocated to this work in the United States, but the most notable achievement of the Foundation so far was the conference organised by their medical board of advisers, and held in Philadelphia in December, 1954 Eighteen of the papers read at the conference have now been published in the *American Journal of Medicine* [1]

Viets reviews the work on the ætiology and treatment of myasthenia gravis carried out since 1934, the year in which Mary Walker's description of the action of neostigmine stimulated interest so strongly Koelle describes recent knowledge of the structure of the motor endplate, gained by new techniques which, he points out, have not yet been used in investigating possible structural defects in myasthenia Van Maanen, in his study of neuromuscular blocking agents, notes that the paralysing dose of decamethonium (C10) is smaller for the tibialis than for the soleus of the cat, the opposite is true for tubocurarine This high selectivity of a blocking agent for different muscles in the same species is in line with the affection of certain muscles—such as the ocular, facial, and pharyngeal muscles—in myasthenia

Electromyographic studies led Johns and his colleagues at the Johns Hopkins Hospital to the conclusion that the myasthenic block was of the competitive curare-like type They also compared the effects of acetylcholine in normal subjects and patients with myasthenia, and they obtained results which they felt could be best explained by a competitive block produced by choline, "released in a normal manner during neuromuscular transmission following hydrolysis of endogenous acetylcholine" Churchill-Davidson and Richardson, on the other hand, have found that patients with mild and localised myasthenic weakness showed diminished sensitivity to decamethonium, while those with generalised weakness did not have this tolerance They also found that the block produced by decamethonium in myasthenic patients is of the dual type and not a simple depolarisation, as in the normal subject—a conclusion opposed to that of Johns et al. Churchill-Davidson and Richardson believe that the underlying dysfunction in myasthenia is an alteration in the way in which the endplate responds to acetylcholine, rather than any change in the amount liberated at the nerve ending The work of Botelho suggests yet another possibility From simultaneous studies of electrical and mechanical activity in myasthenia, she finds that tension changes at stimulation rates of 3 per sec and 30 per sec are a closer reflection of muscle weakness than are changes in action potential Botelho suggests that myasthenia may be at least partly due to changes in the contractale ability of the muscle, neostigmine being capable of restoring contractility when no alteration in neuromuscular transmission can be shown

Andrew and Harold Wilson have continued their ork on thymic extracts from myasthenic patients, ormal adults, and fœtal whales The blocking effects ey obtained with thymic extracts were not found in milar preparations of lymph nodes and voluntary uscles They feel that an increased thymic secretion xplains the cure of myasthenia by thymectomy, but might in time lead to irreversible changes at, or near, the neuromuscular junction, and this would account for the failure of thymectomy in some cases of long-standing myasthenia Eaton and Clagett give an extensive critical review of the results of thymectomy in the United States, and they also refer to Keynes's British series, the largest of all. They had been sceptical of their own results in 1949, but when they later re-examined them, excluding the patients with thymomas and dividing the remaining patients into groups according to sex and age, they found that surgery was significantly better in young women, in whom 53% of results were "very good," compared with 25% in a similar series treated medically In men the advantage of surgery was slight—35% of good remissions as opposed to 30% with medical treatment They agree with Keynes that the prognosis is much worse with thymomas and that operation should be preceded by irradiation

Discussing the influence of pregnancy in myasthenia, Schlezinger finds that equal numbers of cases improve, get worse, or remain stationary during pregnancy The behaviour of the disease during one pregnancy is no guide to what may happen to the patient during a subsequent pregnancy Schlezinger draws attention to previous reports of transient myasthenia in the newborn offspring of an affected mother The recognition of this possibility by the obstetrician and the treatment of the infant with neostigmine may be life-saving

Schwab has treated 60 patients with the new drug WIN 8077 ('Mysuran') This drug has a stronger anti-curare effect than neostigmine and its action lasts about twice as long It produces the same undesirable side effects which, because of its prolonged action, may be more serious, calling for caution and very gradual increase in dosage when stabilising a patient Schwab et al [2] have since reported that 59 out of 75 patients were being satisfactorily maintained on this drug

Osserman describes further results with pyridostigmine ('Mestinon') He confirms that many patients get fewer side-effects than with neostigmine and like pyridostigmine, especially because its slightly longer action often makes a night dose unnecessary Tether [3] has lately recorded further experiences which reinforce earlier encouraging findings with this drug [4]

At the Philadelphia conference Tether dealt in detail with the management of myasthenic crises He gave examples of patients who were treated too energetically and carried from a myasthenic crisis to a cholinergic crisis One of his patients had reached the astonishing dose of 215 tablets (3225 mg) of neostigmine daily towards the end of pregnancy Patients requiring such large doses are more safely managed by frequent injections, since uneven absorption is a serious and uncontrollable hazard when tablets are given in large numbers

INDEX OF THE LANCET

OUR Index for the second half of last year should have been issued many weeks ago, but the recent interruption in the work of our printers has prevented their completing it We hope next week we shall be able to say when it will appear

---

DR ÉDOUARD RIST, chief physician to the Laennec Hospital, Paris, has died at the age of 85 He was a past president of the French Tuberculosis Society and was elected a fellow of the Royal College of Physicians o London in 1940

DR MATTHIEU PIERRE WEIL, the news of whose deat has reached us, was for many years head of Fernan Bezançon's clinic in the Hôpital St Antoine in Pari His great intelligence, his warm heart, and his orator made him for many years a well-known and well-love figure at international congresses on rheumatology.

to have a semitransparent tube, although the present tube size is not ideal and a thinner walled tube would be better

Silicone rubber's excellent heat-resisting properties would allow it to be sterilised at a temperature high enough to destroy any protein contaminants

The disadvantages of this tubing are its high initial price (offset by its durability) and its unsuitability for use in the operating theatre with explosive anæsthetics, or by an oxygen tent It may be possible in the future to produce silicone rubber with better conducting properties

The silicone rubber tubing was prepared by Midland Silicones Ltd, London, and the sets were assembled and sterilised by the courtesy of Dr W Weiner, Birmingham Regional Blood Transfusion Service The electrical properties of silicone rubber tubing were examined by Mr A Quinton, principal physicist to the Queen Elizabeth Hospital, Birmingham

TREATMENT OF NEPHROSIS WITH PREDNISOLONE

SIR,—It has been pointed out to me that in seeking brevity some ambiguity as to the dosage of prednisolone used by me in the treatment of nephrosis may have been introduced into table I of my paper published in last week's issue

The dosage recommended in the form of oral tablets of prednisolone was

60 mg daily for 10 days
40 mg daily for 10 days
20 mg daily for 10 days
10 mg daily for 10 days

Royal Hospital for Sick Children,
Glasgow, C 3

FAMILIAL HEMIPLEGIC MIGRAINE

SIR,—Many people with headache do not have migraine, and some people with undoubted migraine (who have the typical visual attacks) do not have headache There is general agreement that environmental factors in the form of digestive or metabolic disturbances and psychological upsets play a part in firing off the migraine attack, but there is little agreement as to what those factors are For these reasons the compilation and interpretation of family histories of migraine over several generations is difficult Migraine is frequently noted in two successive generations, but it may be sufficiently common in the population for it to behave in this way whether the innate tendency were conveyed as a mendelian dominant or recessive character

The peculiar form of migraine known as hemiplegic migraine does not share all these genealogical disadvantages, however It is very rare, and the nature of the attacks is so striking that a fairly accurate, if secondhand, account of them should be obtained even when the affected person is no longer living The attacks are usually very similar in different members of the family Several workers have recorded cases in more than one member of a family, and the most recent account, by Blau and Whitty,[1] concludes "The condition appears to be inherited through a recessive gene and is not sex linked" Of these two conclusions the first seems to be untenable, and Dr Blau and Dr Whitty have since amended it (Feb 11) by stating that the condition is apparently inherited through an irregular dominant gene Their second conclusion is unproven from the data provided

Good descriptions of the disorder are given by Symonds[2] and by Blau and Whitty[1] In the accompanying figure A is the family tree from the latter paper This shows direct transmission through three, and in one instance four generations This in a rare condition is by itself practically proof of a dominant inheritance, the only exception to this mode of inheritance in this family being the individual III 6, who transmitted the disorder though escaping herself Presumably this exception led the authors to postulate a recessive heredity, but for this to be the case, no less than 4 individuals in this small family group must have married persons heterozygous for the complaint, which, in the absence of a series of consanguineous marriages, would in such a rare condition be beyond any likelihood It is quite common for a dominant condition to skip a generation (the phenomenon known as incomplete penetrance) Assuming that the individual III 6 carried this dominant gene, the offspring of affected individuals are exactly as they should be for dominant transmission 8 inheriting the gene and 9 unaffected None of the unaffected members (except III 6) had affected children

Other records, as far as they go, support a dominant transmission Dynes[3] recorded hemiplegic migraine in a mother and daughter, and Symonds[2] in two families—father and son in one, grandfather father, and son in the other Whitty[4] recorded three families, consisting of mother and daughter, father and daughter (in which the father only had ordinary migraine), and the family illustrated in the accompanying figure, B Clarke[5] recorded in detail the extraordinary family illustrated in the accompanying figure, C In this family the individuals I 1 and 2 were said to be free from the complaint, but as they were probably born about 1810 the information may not be complete Perhaps the environmental stimulus for firing off the attack did not occur in those days They had a "very large family" of whom 4 certainly, and a 5th probably, had hemiplegic migraine As the number of sibs in this generation is not recorded and as 4 of the children in generation IV were still very young when the family was investigated, there is not much to be gained by calculating the ratio of affected to unaffected offspring

With regard to sex linkage, indications of the well known form (a recessive gene on the X chromosome) are of course lacking A dominant gene on the Y chromosome is also ruled out, but there is nothing in Blau and Whitty's family to exclude a dominant gene on the X chromosome It is, however, ruled out by pedigrees B and C in which affected males have transmitted the disorder to male offspring A dominant gene on the homologous portion of the sex chromosomes is more difficult to rule out but pedigrees B and C

ABLE II—AGE OF SEPARATION AND AGE OF FIRST THEFT

—	Separated before 2 years old	Separated after 2 years old	Not separated	Total
ore 7	12	4	9	25
er 7	22	18	125	165
Total	34	22	134	190*

$\chi^2=43\ 68 \quad n=2 \quad P<0\ 001$

* Information was unreliable in 10 cases

The importance of unconscious symbolism in many efts by children has been described by many writers, cluding Schmideberg (1935), Bowlby (1946), Fenichel 946), and Gardner (1947), but opinions vary on inter etation Some workers emphasise that the stolen ods represent affection, of which the child has had less an normal, others hold that the theft is predominantly gressive—the main motive being to injure the victim he present study suggests that in different offences oth these motives, and others, are present Whatever e motivation of an offence, however, clinical examina on repeatedly confirms the truth of Healy and Bronner's 1936) remark

> “ Young people enter into delinquency commonly not with ny deliberate rejection of ethical standards nor as a rational nterprise Later on in life, when criminalistic skills are cquired and material gains result the story may be lifferent delinquency in these early years represents mainly a welling up of blindly active responses ”

Results

I observed no connection between type of offence and intelligence But there was a clear association between type of offence and age (table I) It is arguable that only older boys would commit secondary offences or steal motor vehicles, but, even with these groups removed, the distribution is statistically significant Table IV shows that proving stealing is not merely the offence of an older and previously delinquent boy

TABLE III—AGE OF SEPARATION AND STEALING FROM HOME AT ANY TIME

—	Before 2 years old	After 2 years old	Not separated	Total
From home	17	12	20	49
Not from home	17	10	114	141
Total	34	22	134	190*

$\chi^2=21\ 55 \quad n=2 \quad P<0\ 001$

* Information was unreliable in 10 cases

The effect of maternal separation in infancy has been stressed in recent years I could find no clear relation between age at, or length of, separation and type of present offence, but a clear association between early separation and early stealing (table II) There was also a clear association between early separation and stealing from home at any time (table III) In other words, children who are separated early tend to begin their stealing early and tend to steal from home An interesting finding, which was, however, not definite enough to be statistically significant, was a positive correlation between maternal rejection and a history of early separation In other words, the history of early separation may be associated with present behaviour because it is also associated with present rejection—this point is often overlooked No importance could be attached to length of breast feeding

The age at which stealing began was related to the type of theft As shown in table IV, boys now committing marauding thefts began to steal between the ages of 8 and 14 This age has been neglected by psycho analysts, who regard it as part of the latency period, but other workers (Hall 1908, Ackerson 1931, Piaget 1932) have shown that it is an active and important age, for boys at least It is the gang age, and marauding offences are gang offences Most of the provers, on the other hand, began rather later, while a large proportion of the comforters and secondary offenders began early in life

The most important part of the study dealt with parental relationships (table V) The clearest association was between maternal rejection and the comforting type of offence, especially stealing from home Some offences are not due to both parents acting together, but to a conflict of attitudes between the parents In both subdivisions of the proving offences there is a similar combination of “ good ” mother and “ bad ” father Father's failing is to be authoritarian (low in democracy) and often inconsistent, while good mothers are often too affectionate An over-protective mother or an authoritarian father may cause rebellion in adolescence—an age at which self-consciousness about masculinity reaches a crisis (Alexander and Healy 1935, Blos 1941, Selling 1942, Elkin 1946) In the marauding group study of the parental attitudes does not show a definite background Compared with the other groups it gives the impression that the parents are reasonably affectionate, but rather inconsistent in their discipline Without a control group it is impossible to say whether this combination is a likely cause of this type of offence or whether it is merely the predominant pattern at this cultural level Experience suggests the latter

TABLE IV—AGE OF FIRST KNOWN THEFT AND TYPE OF PRESENT THEFT

Type of offence	Age				Total
	Before 7	8–11	12–14	15–17	
Marauding	2	32	26	5	65
Proving	0	5	10	10	25
Comforting	15	18	14	6	53
Secondary	7	10	3	2	22
Other	2	14	15	4	35
Total	26	79	68	27	200

$\chi^2=50\ 28 \quad n=12 \quad P<0\ 001$

Consideration of the socio economic level showed further differences (table VI) Comforting offences spread over the whole range, proving offences are commoner

TABLE V—TYPE OF THEFT AND PARENTAL ATTITUDES

—	Democracy				Acceptance				Indulgence				Total
	Maternal		Paternal		Maternal		Paternal		Maternal		Paternal		
	Good	Bad	Good	Bad	Good	Bad	Good	Bad	Good	Bad	Good	Bad	
Marauding	30	26	22	30	31	24	27	25	26	30	21	28	320
Proving (*b*)	12	2	2	9	8	2	4	4	10	4	2	7	66
(*c*)	7	3	2	7	7	0	5	1	7	2	2	4	46
Comforting (*a*)	7	12	2	12	3	23	4	13	5	14	4	10	109
(*b*)	10	10	4	15	8	15	8	13	10	10	5	12	120
Secondary	7	7	2	11	9	8	4	8	7	7	3	9	82
Other	19	9	11	13	25	8	13	9	17	11	7	13	155
Total	92	68	45	97	91	80	65	73	82	78	44	83	898

“ Good ’ is a combination of ‘ high and medium ’ in acceptance and democracy, and ‘ Medium ” alone in indulgence (as “ high ’ indulgence from the working definition would be considered to be ‘ over ’ indulgence)

A rating of “ *high* ” in acceptance should also probably be considered bad, because it includes the over affectionate mother but if it had been rated “ bad ” it would have masked an interesting finding in the proving group

TABLE II—RESULTS OF DUAL READING

Classification	Both observers	Observer A	Observer B	Action*

Active post primary unilateral	31 (*72%*)	31 +7 (*88 4%*)	31 +5 (*83 7%*)	43
Active post primary bilateral	15 (*100%*)	15 +0 (*100%*)	15 +0 (*100%*)	15
Total	52 (*77 5%*)	52 +9 (*91 5%*)	52 +6 (*86 5%*)	67

* Sent to chest clinic for full investigation and treatment

films was prepared Those persons were then re-examined radiographically Meanwhile, the miniature films were read again by the director of the other unit, and the persons he wished to recall whose names and numbers did not appear on the first list were recalled in addition

A register was kept, which showed the numbers and names of those persons recalled by observer A on the left-hand page and by observer B on the right hand side It was thus easy to see which persons had been recalled by both observers During the course of several months the results from 10,000 people were collected

All the large films were read and reported on independently by both observers and classified for tuberculosis under the old mass X ray classification

20 active primary
22 active post primary unilateral
23 active post primary bilateral

We are concerned here only with cases which were considered to be active by one or both observers (although this does not necessarily mean they were clinically active) and with the efficiency of miniature film reading

The survey revealed a total of 67 cases which were agreed by both observers to require further clinical investigation The results of the dual reading of the miniature film of these cases are shown in table II

It is clear that in many of the observer-error trials, opinions are expressed on figures which are far too small Thus the much quoted American figures of one series were based on 30 subjects out of 1800 students, Stradling and Johnston's figures [5] on 198 out of 1000, and our own on only 67 out of 10,000

Both observers recalled only 77 5% of the total, but each separately did better A recalled 91 5% and B 86 5% In other words, under-reading of agreed abnormals was 8 5% by A and 13·5% by B These figures are in close accord with those of Stradling and Johnston, who stated that "It will be seen that our under-reading error when viewing single postero anterior films alone is 9 11%"

Other American figures, quoted by Birkelo and Yerushalmy in 1947, were that for 1256 persons, 131 films were called "positive" by one or more readers and for different readers, the number varied from 56–100

Stradling and Johnston in considering the under-reading error, which appears lower than that found by the American workers, quote factors which may be of importance

(1) The American figures relate to minimal tuberculous lesions, whereas theirs contain the mixed abnormalities observed in routine practice

(2) The agreed abnormals in the American series are relatively small groups, 30 out of 1790 Their English group contained a higher proportion of abnormals—198 out of 1000

In our results, so similar to theirs, these factors do not obtain, for most of our cases involved minimal lesions occurring in National Service recruits, and, moreover, they were diluted, not at the rate of 30 out of 1790, but 67 out of 10,000

As far as the mass X-ray cases are concerned, it would appear that there is greater difficulty in recognising active primary lesions and the least difficulty from *bilateral lesions—but it is clear that far more extensive* trials would be necessary to elucidate these points

It must be borne in mind that these 67 cases labelled "active" are not by any means necessarily so In fact, in mass surveys, the majority are reported on by the chest clinics as inactive and not requiring treatment If half the cases were active, which may be so in this series since most were found in National Service recruits, then the number of truly active cases missed by A was around 5% and by B 7%

We have discussed this problem with Dr Peter Kerley and he agrees with us that observer error is significantly increased (*a*) by indifferent technique, (*b*) by inexperience and lack of training, and (*c*) by attempting to read too many films too quickly All these factors could readily be eliminated Many people are using X-ray apparatus without any training in technique and they lack experience of the quality of film required In addition, many readers have insufficient experience of minimal lesions and are apt to miss them or fail to appreciate their significance

VISITING IN MENTAL HOSPITALS

Sir,—Dr Salfield is right when he states that mental disorder, though sometimes treatable by physical means, remains *mental*, right again, when he suggests that no problems of life can be solved by physical treatment, but he is wrong in not agreeing that unrestricted visits is the first essential It is simply because the illness is *mental* that we must never lose sight of the fact that the sole objective of psychiatry is to ease the minds of the mentally ill

Although we like to pretend otherwise, the fact is that by far the greatest number of admissions are those admitted against their will, and it is only natural that these frightened and bewildered persons should seek that sympathy, comfort, hope, and assurance that *only* relatives and friends can give Moreover—apart from the fact that my opinion is based on a point-blank study carried out continuously for seventeen years—I should like to remind Dr Salfield that the Royal Medico Psychological Association represents the great majority of our psychiatrists, and that it was their representative committee who proudly informed the Royal Commission of their unanimous desire for unrestricted visits

That there is a shortage of nursing and medical staff is true, it is to be regretted and deplored, but it is, however, beside the point

Edzell, Angus H G Woodley

RESIN-REINFORCED PLASTER CASTS

Sir,—In 1953 I reported the results of a trial of plaster casts using bandages soaked in a freshly prepared solution of melamine resin with ammonium chloride as catalyst [1] At that time I suggested that it would be helpful if the resin and catalyst were incorporated in plaster bandages Such bandages have been produced, and I have tried them with similar results to those reported previously

The casts made from them are lighter, stronger, and more durable than those made from ordinary plaster bandages Moreover, it is noted that when one has finished making a plaster cast, hardly any plaster has *fallen out of the bandage into the basin containing the* water used to moisten the bandage This is in sharp contrast to the heavy deposit found when bandages are home made and to a lesser extent when machine made Sayle Creer [2] confirms this The cost of these bandages is slightly greater than that of the ordinary plaster bandage, but in practice fewer bandages are needed, thus in the end effecting a saving For example, a satisfactory wrist cock-up splint was made using only one bandage as an anterior slab, and fixing it with a gauze bandage It weighed 107 g when dry, compared with 184 g when

All of these are extremely dangerous to life ldiction to methylated spirit is explained by the fact at the spirit consists mainly of ethyl alcohol

In our addiction unit we discourage the notion that e drinker of methylated spirit is a lower type than her addicts to alcohol We find he is almost equally pable of rehabilitation Indeed drinkers of methylated rit show some favourable qualities · for the most part ey live quietly and cheaply, often sleep rough, and rgely keep out of the way of other people Most of em do casual work and live and drink at a very low ost Among our patients the incidence of theft petty aud, begging, and all crimes other than drunkenness, , remarkably low We know of no type of patient who esponds with such warmth to sympathetic interest and riendliness

Methylated Spirit

The official name is industrial methylated spirit It sold mainly for use in industry, but certain domestic ises—e g , as fuel for spirit-lamps—are also recognised The Methylated Spirit (Sale by Retail) Scotland Act, 1937, secures that the purchaser enters in a register his name, address, the quantity obtained, and the purpose or which the spirit is to be used. Sellers have to be registered with the local authority, and a label on the bottle must indicate the name and address of the seller ere is no similar restriction to the sale of surgical irit, which by volume is just over 95% methylated spirit

The *British Pharmaceutical Codex* (1954) defines methylated spirit as " a mixture, made by a legally authorised methylator of 19 volumes of alcohol (95 per cent) with 1 volume of approved wood naphtha " The latter substance consists mainly of methyl alcohol and gives to the mixture its 4% of that substance The *B P C* describes the spirit as " a colourless mobile volatile liquid with an odour of alcohol and wood naphtha and a burning taste "

The taste is so repulsive that aversion to it is never ercome, but when it is highly diluted with water, all soned drinkers find it potable When occasionally ey can afford cheap wine or beer, however, they prefer fortify these drinks with methylated spirit Sometimes hey will add the spirit to tea or to sugared water

Methylated spirit is less dangerous to life than is often supposed We have never found the specific lesions of poisoning with methyl alcohol—i e , optic neuritis or atrophy—in any of these patients The findings are the same as in cases of prolonged overdosage with ethyl alcohol For instance, polyneuritis is often present Addicts to methylated spirit show a slightly higher incidence of this condition than do addicts to other alcoholic drinks, but this may be wholly due to the fact that they tend more than the others to neglect their general nutrition while drinking

That the effects of these two types of drinking differ so little from one another is probably because methylated spirit contains only 4% or less of methyl alcohol, and the overwhelming preponderance of ethyl alcohol tends to prevent the oxidation and conversion of the methyl alcohol to formic acid Indeed ethyl alcohol can be used effectively in the treatment of poisoning by methyl alcohol

In Great Britain, fortunately, methylated spirit and its derivatives are the only liquids containing methyl alcohol that are used widely or regularly The drinking of concoctions containing a high percentage of methyl alcohol has been rare and almost limited to the latter period of the late war and the immediate post-war years in which whisky remained scarce In all such cases the victims obtained " whisky," &c , from irregular sources, thinking that they were buying good drink In the U S A during the prohibition period wood alcohol with a high content of methyl alcohol was sold by some bootleggers, and 444 deaths due to poisoning by methyl alcohol from this source were recorded in 1931.

The Addicts

Weeks (1938) states

" Methylated Spirit drinking is the last stage of alcoholic excess , no one ever starts to drink such stuff, but when the appetite has been whetted by other forms of alcohol, when means to buy decent drink are not available and craving comes, these unfortunate victims turn to anything "

Weeks showed, perhaps, a little less than his usual sympathetic understanding in this summing up We cannot agree that the drinking of methylated spirit is " the last stage of alcoholic excess " Addicts to ordinary alcohol can and do go to hell as effectively and more devastatingly than the drinker of methylated spirit when having used up their normal resources, they insist on still drinking brandy or whisky at the expense of selling their furniture, realising on life policies, mortgaging houses, " borrowing " from relations and friends, &c Also the " whetting of the appetite by other forms of alcohol " is not our experience of drinkers of methylated spirit Not, one of them developed a *preference* for methylated spirit . all would have preferred to continue drinking whisky

Emotional blunting, a tendency to vagrancy, pessimism of outlook and depression are characteristic of typical drinkers of methylated spirit They are also poorly socialised but nevertheless show a pseudo gregariousness by sharing sleeping-out places—e g in yards and lofts of brick-works Their drinking too is often communal because it is more economical to share a bottle among a group This description closely resembles the classical picture of simple schizophrenia We do not however, find that these people are actively psychotic Their auto sedation, their self-exclusion from friction with society, and the leaning on each other of the group life they evolve seem, in combination to save them from psychotic breakdown They are not solitary, bearded, and almost wordless tramps like the schizophrenics of the type they resemble They may be down-at-heel and shabby, but they retain an interest in washing and shaving

Of the 21 male drinkers of methylated spirit who were inpatients in 1955 all but 3 showed the personality features outlined above Cases 3 and 7 (see below) are 2 of the 3 atypical cases Both of these men are hearty hypomanic extraverts

Not one of our drinkers of methylated spirit has been a dullard or mentally defective All have been average or above average in intelligence

Admissions

The Addiction Unit was started at Gartloch Hospital in March, 1950 An Alcoholics Anonymous (A A) group was founded at the hospital in January, 1951 This was the first hospital A A group, affiliated to the parent body, to be founded in Europe From the patients drinkers of methylated spirit were among the first admitted, the first, a man with over 200 convictions, arriving in May, 1950 The following are the figures

Year	*Addicts to alcohol*	*Drinkers of methylated spirit*
1950	30 (3 F)	3 (10 0%)
1951	44 (6 F)	3 (6 8%)
1952	97 (7 F)	5 (5 1%)
1953	113 (4 F)	12 (10 6%)
1954	133 (6 F)	15 (11 3%)
1955 (to end of July)	134 (4 F)	22 (1 F) (16 4%)

F, female

The 60 drinkers of methylated spirit include only 1 female, and the 549 addicts of alcohol include only 30 females In each case our figures give a misleading impression of the sex-distribution nationally, which is probably about 9 males to 2 females The explanation is that the Addiction Unit has grown up on the male side

I wish to thank Prof J Rutkowski and Prof R Pakula for their valuable advice, and Dr B Marzinek, Dr M Brzeziński, Dr M Baranski, and Dr L Landowski for their help in the investigations I administered to these patients 'Distreptase,' containing both enzymes, and sometimes either streptokinase or streptodornase In all these cases I used only the products of the Polish Institute of Hygiene

Surgical Ambulatorium
of the Health Department,
Warsaw

HENRYK RYKOWSKI

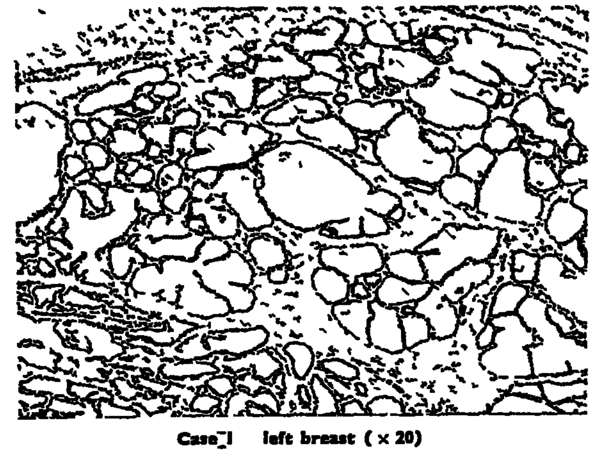
BREAST CHANGES IN FIBROCYSTIC DISEASE OF THE PANCREAS

SIR,—In raising the question of the relation of breast enlargement to fibrocystic disease of the pancreas, Dr Jolly[1] referred to three cases in which these conditions coexisted One of these cases has now come to necropsy and we report here the clinical and histological findings The clinical aspects of a second case, still alive, are also presented

CASE 1, a female, was first seen at 2 weeks of age, when mucoviscidosis was diagnosed Both breasts were much enlarged Subsequently treatment consisted in administration of oxygen and, at different times, penicillin, oxytetracycline, chloramphenicol, and erythromycin but not aureomycin The breasts remained in the same state till death at the age of 6 weeks Necropsy revealed cystic fibrosis of the pancreas and suppurative bronchopneumonia, from the lungs *Pseudomonas pyocyanea*, an anthracoid bacillus, *Staphylococcus albus*, and a non hæmolytic streptococcus were isolated From the enlarged breasts a thin opaque secretion could be expressed, and on section (see figure) greatly dilated ducts and acini, lined by a flattened epithelium, were set in a dense fibrous stroma, there was little secretion in the cystic spaces Mucin stains (mucicarmine and periodic acid/Schiff reaction) of breast and pancreas gave indefinite results

CASE 2 is a female, aged 2 years, in whom mucoviscidosis was diagnosed at the age of 1 month, when the breasts were not enlarged Enlargement was observed by one of us (C E S) between the ages of 5 and 14 months, when aureomycin was administered intermittently Subsequently aureomycin therapy was stopped, and the breast enlargement subsided and has not recurred This child's elder sister also has mucoviscidosis and treatment included aureomycin, but no enlargement of the breasts was observed

Since the breast is essentially a serous gland, Lightwood[2] felt that it was unlikely to be involved in fibrocystic disease of the pancreas, but di Sant' Agnese et al[3] found that the electrolyte composition of the sweat was abnormal in this disease and suggested that all exocrine glands, whether mucus producing or not, are affected We know of no reference to morphological changes in the breast or sweat-glands in pancreatic fibrocystic disease, and accordingly in case 1 the alternative diagnosis of "neonatal mastitis" was considered Forssell[4] described 92 cases of this condition and showed that secretion of "witch's milk" and the associated histological changes not infrequently persisted for several months In the light of Forssell's observations we conclude that case 1 is an example of "mastitis neonatorum"



Case 1 left breast (× 20)

Our experience and that of others[1 2 5] might suggest that there is more than one cause of breast enlargement in mucoviscidosis Enlargement soon after birth almost certainly represents "mastitis neonatorum," but in other cases the swelling occurs later and may be related to antibiotic therapy "Mastitis neonatorum" is ascribed by Forssell to maternal œstrogens If certain antibiotics augment the circulating œstrogens by reducing vitamin B intake,[5 6] then breast enlargement after their administration, whether in mucoviscidosis or not, has a fundamentally similar pathogenesis to that of "mastitis neonatorum" We have not yet had the opportunity of studying the histology of enlarged breasts following aureomycin or oxytetracycline therapy, but on this hypothesis the structural changes should be similar to those in case 1 In Dr Jolly's cases of fibrocystic disease, enlargement of the breasts was not apparently related to aureomycin treatment, but aureomycin is not the only drug associated with breast enlargement,[5] and it would therefore be of value to know if his cases received any other antibiotics If aureomycin and oxytetracycline act by interfering with assimilation of vitamin B the response to vitamin-B therapy would be worth knowing It is difficult at this stage to explain why breast enlargement affects only some patients who receive aureomycin

ORDEAL BY TREATMENT

SIR,—In recent visits to a friend in a surgical ward, I have been shocked by the changes that seem to have taken place in the ten years since I myself had several major operations Perhaps it may be useful to doctors to know how this transformation strikes a layman

Starting before operation, the passage of a nasal tube is presented to the patient as a great modern boon which prevents postoperative pneumonia But this "boon" can be a humiliating and painful affair I myself saw patients coughing, choking, and struggling as the young nurse tried and tried again to work the long tube up the nose and down the throat

As soon as possible after recovering from the anæsthetic, the patient is made to do exercises with the hands, later with the arms and head Vigorous young women come round and pommel him on the back saying, "now please cough," again and again One can hear patients swearing and groaning under this treatment

Beds being still scarce, there is a strong desire to get rid of the patient quickly There is also immense pride in getting him up and walking within a few days of the operation To the layman it seems little short of lunacy that, seven days after big abdominal operations, the patients who were so recently very ill should be struggling about and going to the lavatory on their own If (as happened in my friend's case) the outside and the inside wound reopens, they just have to be in for another week—too bad To boast about young people being out of bed twenty four hours after an appendicitis operation seems to me like boasting about car speed records—and on the same level

Judging by what I have seen, and heard from patients who have had major operations, no forty five minutes pass between 6 30 A M and 10 P M but a nurse appears with a needle for an injection of penicillin (every four hours), or of some vitamin, or of something to prevent the blood from

[6] Biskind, M S, Biskind G R *Endocrinology*, 1942, 31, 109

4, to December, 1955) About 50 were, in fact, sent during the whole two years In January, 1955, re were 58 chronic schizophrenics, 9 deteriorated leptics, 1 G P I, and 1 case of organic dementia The erage stay in hospital was over eleven years

The Ward was on the ground floor, shaped liked a V, th entrances on the main corridor at each end It ntained a dining room and day-room, separated by a ass partition, with a single large dormitory leading off e day-room The floors were of parquet The ward d not been painted since 1925, and the prevailing colour heme was olive green and black The day room urniture consisted of bench-type seats and single chairs n a bad state of repair and many damaged by patients), There was full size billiards table, and a television set closed garden leading out of the ward

THE PROBLEM

his ward, with its drab and depressing appearance, d complement of deteriorated patients, was looked on the nursing staff as a hopeless task Their attitude wards it was one of resignation and acceptance of the recarious equilibrium The main object was to prevent ny aggressive behaviour by patients, who were put to ed if they were at all disturbed About two thirds of them spent most of the day sitting in the day-room or (in fine weather) in the ward garden The remaining third were actively employed on ward work, or in other simple occupations The junior nurses regarded their duties on this ward as a necessary part of their syllabus, but beyond this they showed no interest, counting it only as so much time to be passed Routine within the ward was sadly lacking, and the behaviour of patients left much to be desired

The general feeling in the hospital was that something must be done, but it was difficult to see where to begin

THE METHOD

In April, 1955, two new charge nurses were appointed, one on each shift, and the problem was presented to them as a challenge There were never more than three nurses on each shift, including the charge nurse, and the working parties which were formed comprised about 17 patients

An important first step was to ensure that all the nurses understood clearly the aims in view and were aware of the support they would receive This was done by meetings between the administrative and ward staff and by frequent ward meetings, two or three times a week at first Within a general framework the charge nurses were given considerable freedom of action and were largely responsible for the details of the reorganisation

This reorganisation was based on three principles useful employment of all patients physically fit, a routine pattern of life within the ward community, and increased attention to social needs

Employment —Owing to their deterioration it was impossible to make any great increase in the proportion of patients employed in hospital departments, though an additional 8 were considered suitable for work in the closed occupational therapy centre All those who had been euphemistically designated as ward workers were reviewed 6 were chosen for ward duties under the charge nurse and the remaining 35 were divided into two working parties Each party was always supervised by the same junior nurse and it was not difficult to find routine work in which even the most withdrawn patient could be encouraged to share For example, these parties have been lifting potatoes, clearing brushwood, and moving and cleaning bricks for use in building a new occupational therapy centre It is important for the nurse as well as for the patients that the work should be useful and not just a way of passing the time

Routine —A set pattern was laid down from the start, and all nurses concentrated on teaching patients this new social pattern at all times in the ward At first it was uphill work Changing of outdoor boots, washing, toilet routine, behaviour at meal times, attention to person and dress, and so on, were continually emphasised, and the routine was underlined wherever possible by association and by adhering to a fixed time table (table I)

During the period of this study 10 patients from this ward participated in a habit training experiment in which efforts at improvement were more intensive This will be described elsewhere

Social Activity —As habits and behaviour improved, more and more patients joined in mixed social activities in the main hall Weekly social evenings were also started on an exchange basis with a similar ward of women patients, when games and dancing were organised on the wards These social evenings evoked more spontaneous reactions from patients, who entered into dancing and team games with less and less encouragement The two working parties were also sent to "Movement with music" classes once a week, where they mixed with similar women patients under the charge of a visiting instructor In addition, they had P T classes every morning with emphasis on team games

In September, 1955, the ward was entirely redecorated in modern pastel shades The staff were pleased, and, though the patients expressed no very positive opinions, there was no defacing of walls and in their cleaning duties patients have preserved the new appearance. Furniture was repaired and re upholstered in the hospital departments and the black iron bedsteads were stripped and repainted in bright colours by patients in the occupational-therapy centre

TABLE I—AVERAGE DAY ON LONG STAY WARD FOR DETERIORATED MALE PATIENTS

35 patients in two groups (I and II)
4 patients unfit
25 reasonably well preserved and working in various hospital departments
6 patients as regular ward workers

7 15 A M	Rise Nurses in charge of groups I and II issue clothing to them from their individual lockers and supervise their toilet and bedmaking Charge nurse supervises remainder who being better preserved mostly look after themselves
8 00 A M	Breakfast
8 30 A M	Group I taken for physical training by instructor Group II ward work Remaining patients out to work in various departments
9 15 A M	Tea break and change into outdoor boots
9 30 A M	The two groups in the charge of their respective nurses do work specified by occupational therapy supervisor (e g, cleaning bricks or digging) or 'basic movement,' Mondays and Thursdays (I or II)
11 30 A M	All patients back in ward Change boots supervision of toilet
12 NOON	Lunch
12 45–1 15 P M	Double shift on—therefore Shaving bathing hair cutting
2 00 P M	All patients including groups out to work or visitors on visiting day or organised games Tuesday and Thursday on recreation field
3 45 P M	All patients back in ward Change boots, supervision of toilet
4 30 P M	Tea
5 00 P M	Social events Cinema, plays dancing, inter ward games inter ward parties television
8 15–8 45 P M	Preparation for bed

THE RESULTS

The Fergus Falls Behaviour Rating Scale[1] was used to assess the behaviour of the 54 patients who were in the ward throughout 1954 and 1955 The 10 in the habit training group showed an average gain of 5 4 points in the six months between April and October, 1955, while the remaining 44 gained 4 2 points

The ward records reflect changes in behaviour and socialisation (table II) The comparison is made between conditions in 1954 and 1955, since the type of patient in the ward remained stable during that period There was aided, if necessary, by an Oxford inflating bellows, using a face mask In cases with moderately severe respiratory paralysis, a portable cuirass respirator, such as the Monaghan, was tried but was ineffective Some patients with very extensive respiratory paralysis, already in a tank respirator, were transferred to the unit A large coach type ambulance with seats removed was supplied, and the patients were transported in an iron lung, the pump unit being operated manually Before the journey a Ryle's tube was passed and *the stomach emptied in case acute dilatation occurred in* the ambulance

1377

Combined Bulbar and Respiratory Paralysis

These cases can be divided into two categories (*a*) established respiratory paralysis with definite bulbar signs, and (*b*) established bulbar paralysis with slight respiratory involvement

Patients in the first of these two groups were, usually not difficult to manage during transport as they had already had a tracheotomy done They were placed on *their back on the ambulance stretcher*, and pulmonary ventilation was maintained by manual operation of an intermittent positive pressure apparatus (e g, Oxford inflating bellows), with or without added oxygen run through the inflation circuit These cases appeared to be the safest to transport, since there was an established airway well below the pooled secretions in the pharynx and larynx Since the endotracheal tube was cuffed, these secretions could not leak into the trachea and main bronchi Tracheal phlegm was easily aspirated by suction through the endotracheal tube Pharyngeal pooling was prevented by frequent suction through the patient's mouth

The patients that caused most anxiety during the *ambulance journey were those with fully established* bulbar paralysis with slight respiratory involvement (e g, with paresis of the lower intercostal muscles) The problem was *to* assess how well *this type of patient could* tolerate a journey of up to thirty miles If a tracheotomy is not considered necessary the patient must be transported in a prone and tilted position, because of the bulbar paralysis But there are certain disadvantages in this position, especially in a moving vehicle The diaphragm has extra work to do, because of the weak lower intercostal muscles, the added weight of the abdominal viscera, and compression of the chest against the stretcher and the paralysis may not yet be at its maximum Some of these patients who had not had a tracheotomy (respiratory aid not seeming necessary) caused considerable anxiety during the journey Their general condition deteriorated, with vomiting, copious secretion of saliva and mucus, and laboured breathing, this happened despite continuous suction from the mouth and pharynx to maintain a clear airway—a life saving but, for the patient, extremely exhausting measure On arrival at the unit some of these patients were very exhausted, with an apparent increase of the respiratory paralysis, in 1 patient an immediate tracheotomy was necessary on arrival In view of our experiences, we feel that a tracheotomy should always be seriously considered in this type of case before the journey, especially if it is a long one It is always safer to transport such a patient with a cuffed tracheotomy tube in position It may then not even be necessary to aid the patient's breathing by intermittent-positive pressure apparatus, and the patient can lie in comfort on his back during the journey Pharyngeal secretions are prevented from entering the trachea by the cuffed tube, and by adequate suction

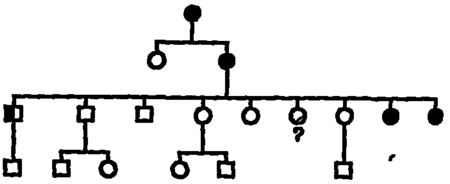
We should like to emphasise the importance of seeking early assistance for patients with the types of poliomyelitis described here Where this was done we found that, as a rule, the transport of the patient caused less anxiety and the prognosis was correspondingly better

We should like to thank Dr E James, under whose care these patients were admitted, for his helpful criticism and advice, and for the opportunity of supervising their transfer

ANTHONY F C SCOTT
BEULAH R KNOX

HAMMER-TOES IN THREE GENERATIONS

SIR,—The accompanying pedigree shows hammer toe in three generations of a family, involving the second toe of both feet in the four females affected and of the left foot alone in the one male affected A fifth female in the second filial generation is said to have shown this condition as a baby but was cured by the application of little splints to stretch the toe, little malformation can be observed now



The flexor digitorum brevis muscle arises from the calcaneum, passes forwards across the arch of the foot, and divides into four tendons, one of which is inserted into the middle phalanx of each of the four minor toes Their action is to flex the middle phalanges on the proximal ones In the present cases the tendon supplying the second toe only is congenitally short, resulting in a hammer toe The parents and two siblings of the progenitor of this condition, together with their fairly closely inbred descendants, show no sign of it

It has been suggested that this is an example of sex limitation

London, E 2 PATRICK JAMES

TREATMENT OF BEDSORES

Dr L GUTTMANN, director of the National Spinal Injuries Centre, Stoke Mandeville Hospital, Aylesbury, Bucks, writes It has been brought to my notice that in 1954 you reported me as recommending, in the course of a lecture, the application to bedsores of a pack moistened with 'Dettol' solution[1] In fact I did not mention dettol, and I consider that the use of this substance is absolutely contra indicated in the treatment of such lesions My views on their treatment have been set out elsewhere[2]

AMATEUR BOXING

Dr J L BRONSTEIN, hon medical officer of the London Amateur Boxing Association, writes Under its medical welfare scheme the association has made it compulsory for all boxers to have an initial medical examination Will those doctors who are interested in amateur boxing and are not already on the panel of boxing medical officers please communicate with me at the London A B A, 69, Victoria Street, London, S W 1, *if they would like to participate in this scheme?*

2 e g, *Brit J plast Surg* 1955, 7 106

enzyme was also responsible for inactivation of sero- n He considered the storage of serotonin in cyto- mic granules in relation to the ability of reserpine elease serotonin

)r H McIlwain described biochemical work by A Wollenberger on protoveratrine, one of the vera- m alkaloids It greatly increased the respiration and colysis of cerebral tissue, decreased its anaerobic colysis and increased its response to electrical pulses ese actions appeared to be due to delaying the ccumulation of potassium ions

Pharmacology of Hypotensive Drugs

Dr J Tripod (Basle) discussed some pharmacological fferences between hypotensive drugs, with special ference to hydrallazine and reserpine Such drugs nded to fall into different groups according to their teraction with a series of pharmacological antagonists, pending on the concentration of oxygen or electro- tes in the medium He had found that the fall in blood- essure produced by hydrallazine could be entirely oolished by previous incubation with certain sera It ad not been possible to identify the constituent of serum ith which hydrallazine reacted Other hypotensive gents, including reserpine did not show this feature

The site and mode of action of reserpine were discussed y Dr Marthe Vogt (Edinburgh) Its hypotensive ction was central in origin and this and its sedative ction might be mediated through the hypothalamus These central actions might be due to the release of large uantities of serotonin (5-hydroxytryptamine) from the owel, brain, and platelets All rauwolfia alkaloids which had a tranquillising action also released serotonin The central actions of reserpine and serotonin were antagonised in the same way by substances such as lysergic acid diethylamide, morphine and methadone On the other hand, central nervous effects resembling those of reserpine had not been reported in patients with argentaffin tumours and a high level of circulating serotonin

Dr W S Peart discussed the β haloalkylamines, which are potent antagonists to adrenaline and noradrenaline One of the most active of these compounds was dibenyline (n-phenoxyisopropyl-n-benzyl chlor ethylamine) In man these compounds produced postural ypotension, miosis and vasodilatation in the skin Their action seemed to be entirely peripheral, locally in the arteriolar wall Dr J G Widdicombe, who dealt with the veratrum alkaloids, said that although they were first investigated over eighty years ago, we still do not know for certain their mode of action in man In animals they produced hypotension and bradycardia by eliciting the Bezold reflex, the sensory end-organs for which lay in the ventricular muscle of the heart In addition it was known that veratrum could cause hypotension by a direct action on the central nervous system The fact that they seemed to exert no effect on the motor side of ardiovascular reflexes, so that postural reflexes were tained had been cited in favour of their therapeutic e in hypertension

The pharmacology of ganglion-blocking agents was discussed by Dr E Zaimis They interrupted transmission in autonomic ganglia by competition with acetylcholine—a mechanism which left preganglionic nerve endings and the ganglion cells unaffected Referring to the tolerance to the hypotensive action of these drugs observed clinically during the initial weeks of their administration Dr Zaimis thought that it was unlikely that this was due to a decreasing sensitivity of the ganglia to the blocking action of the drugs Clinical observations suggested that no tolerance developed in parasympathetic ganglia Further, animal experiments showed that sympathetic ganglia acquired increasing rather than decreasing sensitivity to subsequent doses It appeared possible that the reduced effect on blood-pressure resulting from repeated administration was due to sensitisation of the periphery to adrenaline and noradrenaline

In the discussion Prof F H Smirk (Dunedin New Zealand) described pharmacological experiments in his department suggesting that reserpine had a peripheral action Dr P B Bradley (Birmingham) said that in the cat the effect of reserpine on the electro-encephalogram was similar to that produced by the intraventricular injection of serotonin Dr M Harington described experiments demonstrating the summation of the actions of single intravenous doses of reserpine and hexamethonium in hypertensive patients There was some evidence to suggest that the hypotensive action of hexamethonium might be potentiated after reserpine

Clinical Applications of Hypotensive Drugs

Prof J McMichael described the results of treating patients with malignant hypertension with methonium compounds for five years Hexamethonium or pentolinium was given by parenteral injection, oral administration being avoided because of irregularity of absorption Recently, small doses of reserpine had been added Of 73 patients with malignant hypertension 11 were unsuitable for treatment, being admitted moribund from cerebral hæmorrhage or advanced uræmia The results were most favourable in 52 patients whose blood-urea level was initially under 60 mg per 100 ml; with methonium treatment, in this group the five year life expectancy was 50% The disappearance of retinitis was the most dramatic event following reduction in blood-pressure, fresh hæmorrhages and exudates vanishing in a few weeks, but papillœdema took from two to ten months to disappear The intense morning headache was immediately and completely relieved Gross and severe heart-failure could vanish dramatically The heart size often diminished notably, but the electrocardiographic changes decreased more slowly In 5 patients a peculiar type of organising œdema of the lungs had developed There was no evidence that treatment with methonium drugs led to deterioration of kidney function Pathological study showed that fibrinoid necrosis in arterioles and glomeruli could undergo collagenisation and healing, but the risks of cerebral thrombosis and hæmorrhage and of coronary thrombosis were still present in proportion to the severity of already established arterial disease

The principles of treatment at the hypertension clinic in the University of Otago were described by Professor Smirk He said that the improvement in clinical manifestations and in prognosis were closely related to the degree of control over the blood-pressure The systolic blood-pressure was kept if possible, between 110 and 140 mm Hg, measured in the standing posture although the range was often 85–160 Over a period of six years, there were 25 survivors out of 44 with malignant hypertension or nearly 57%, the survival-rate in the Keith-Wagener series of untreated patients was 2% in the same period In the past six years 320 patients in grades II, III, and IV had been treated and there had been 80 deaths—a survival-rate in all groups of 75% In the past eighteen months treatment had been with pentolinium usually administered orally, together with one of the rauwolfia alkaloids Patients first spent five whole days a week at the clinic and the blood-pressure was recorded every half-hour by a technician As improvement took place, the patients attended for two whole days a week, then one day, and finally they attended only occasionally Advantage was taken of the standing or sitting posture to enhance the decrease in blood-pressure Patients sat propped up at night, or else the head of the bed was raised on blocks Professor Smirk said that he had tried 'Ecolid' and mecamylamine, but they both produced malaise, and parasympathetic side-effects were prominent

Royal Australasian College of Physicians

At the annual meeting of the college held in Wellington, New Zealand, in March, the following took office for 1956–58

President, Dr E G Sayers, vice presidents, Dr Bruce Hunt, Dr C H Fitts, Dr C R Burns censor in chief Dr T M Greenaway, honorary treasurer, Dr W P MacCallum, honorary secretary Dr H M Rennie, past president, Dr C G McDonald

The following were elected to the fellowship

Dr A J Barnett Dr J J Billings, Dr H W Garlick Dr D R Gauld, Dr E A North, and Dr R F A Strang (Victoria), Dr S P Bellmaine, Dr A E McGuinness and Dr R B Perkins (New South Wales), Dr O Hirschfeld (Queensland), Dr E G Saint (Western Australia), Dr E G Sims and Dr R T Binns (South Australia)

The following, having satisfied the board of censors in New Zealand, were admitted to membership

Dr J Apthorp, Dr D W Beaven, Dr M I Bostock Dr D S P Dickson Dr G L Glasgow Dr J D Sinclair, Dr P Fleischl Dr J V Hodge, Dr M J A McDonald, Dr A R Stone, Dr V I E Whitehead, Dr A C H Wilkinson

Dr R H Black and Dr H M Whyte of New South Wales were admitted to membership under the special provisions of article 37

Institute of Diseases of the Chest, London

Clinical demonstrations are being given by Dr F P Lee Lander at the institute (in the grounds of the Brompton Hospital, Fulham Road, S W 3) on Fridays and will continue till July 6 All the meetings are open to doctors without fee and will be held at 5 P M

Vital Statistics in Psychiatry

The Society for Visiting Scientists is holding a discussion on this subject on Wednesday, April 25, at 7 30 P M, at 5, Old Burlington Street, London, W 1 Prof Aubrey Lewis will preside, and the speakers will be Dr Vera Norris, Prof L S Penrose, F R S, and Dr Peter Sainsbury

Service Appointments

Dr F C Golding has been appointed honorary civil consultant in diagnostic radiology to the Royal Air Force

Sir John Parkinson, on resigning his appointment as civil consultant in cardiology, has been appointed honorary consultant in cardiology to the R A F

Miss B Nockolds, R R C, has been appointed matron in chief of the Queen Alexandra's Royal Naval Nursing Service

Cancer Consultation Clinics

For twelve years the Royal Marsden Hospital has been running joint cancer consultation clinics between physicians surgeons, and radiotherapists in association with a group of London hospitals including the Brompton Hospital for Diseases of the Chest, the Chelsea Hospital for Women, the Royal National Throat, Nose, and Ear Hospital, Moorfields, Westminster, and Central Eye Hospitals, the National Hospital, Queen Square, and St Peter's, St Paul's, and St Philip's Hospital Over 1000 new patients are now seen each year On Friday, May 11, an all day meeting (10 A M – 5 P M) is to be held at the Royal College of Surgeons, Lincoln's Inn Fields, W C 2, to report on the work of the group, and on the following morning there will be a demonstration at the Royal Marsden Hospital Programmes of the meeting may be had from the House Governor, Royal Marsden Hospital, London, S W 3

Presentation to Sir Thomas Fairbank

Sir Thomas Fairbank's former house surgeons at King's College Hospital, and other colleagues who worked with him there and at the Hospital for Sick Children, Great *Ormond Street*, have presented him with his portrait by Mr Maurice Codner, R P Proposing his health at an informal dinner held in London on April 14, Mr Harold Edwards said that the reason for the presentation was not his world renown as an orthopædic surgeon (though they were intensely proud of him on this account) but their respect and affection for him as a leader and a friend To those who had had the good fortune to work for him during their formative years he had set a standard, both professional and ethical, which had been of incalculable benefit The portrait was formally presented by Dr Alfred Mitchell the oldest house surgeon present, and Mr H L C Wood the present senior orthopædist to the King's College Hospital Dr W H Scriven then presented Lady Fairbank with a framed photograph of the portrait, in recognition of her many kindnesses to the former house surgeons, both before and since Sir Thomas's retirement

Chelsea Clinical Society

The annual dinner of this society will be held at the Rembrandt Hotel, Thurloe Place, S W 7, on Tuesday, May 1 at 7 30 P M The Marquess of Salisbury will attend

---

At the invitation of the Royal Colleges of Surgeons of England and Edinburgh and the British Council, Prof Peter Andreevich Kupriyanov, principal of surgery in the Kirov Military Medical Academy at Leningrad, Prof Andrew Gregorievich Savinikh, principal of surgery at Tomsk Medical Institute, and Dr D D Benediktov, director of the surgical clinic of the Second Moscow Medical Institute are visiting this country from April 15 to May 5

CORRIGENDUM *Pulmonary Embolism and 5 hydroxytryptamine*—In the second paragraph of Dr Kenneth Carter's letter last week (p 446) the third sentence should begin "Replacing one benzyl group by a phenoxyisopropyl group results in *n* phenoxyisopropyl *n* benzyl β chlorethylamine hydrochloride "

In England Now

Running Commentary by Peripatetic Correspondents

IVING in Canada is a long-term proposition I bled oldest donor yesterday—a little old man, spry as come, a bit deaf, and with bright blue eyes which sed nothing peering out through slits in parchment

Want you to take some blood," he said "S'alright, tor sent me Been having headaches all winter an' got a in me shoulder" His hands quietly rolled invisible pills monstrated "Go on," he said, "nothing like it to set ye Do it for meself if I didn't shake too much"

e jumped up on our high donor couch like a 10 year old illed up the sleeves of his sweater and of a long woollen Across each elbow, over the cephalic veins, were old, te, transverse scars "Used to do it in the bush," he said, st thing when you're out of sorts Laid up all one winter a pains in me ear Doctor filled me up with pills, tons of , got fed up with it So I bled meself—into a soup plate I sweated Must 'a been a quart of it Next day, back to k, good as ever"

is pulse never wavered as I bled him, and he reminisced unting All me life Love it Got me a buck last month 't carry 'em home now, though Can't walk like I used to ried 200 lb *once*" *He accepted hot milk, refusing tea,* showed me his blood letting implement It was a small ss sheathed gadget like a penknife, a triangular steel de protruding from the end You pressed it back against a ng, held it against the vein, and released a catch The de sprang down, incising the vein with a clean, 0 5 cm, cut on t think he ever sterilised it

e is 89 And in November we're going up North moose

* * *

or many years twelve learned men met once a month study the appearance and behaviour of strange mals They examined their form, their appetites, ir desires, and above all they were well up in the rature of their subject They then classified each mal and gave it a number with up to three decimal nts

ut all was not well For some time they had used a egory for the unicorn, and after ten years they found t they had classified no less than eleven animals in s way, giving them the code number 1 322 Soon the ling began to spread that there might be no such mal, and they called a special meeting to consider the nt The literature on the subject was definite The icorn was an animal like a horse which had a single nder horn projecting from the centre of its forehead e Chairman maintained that most of the animals so ssified either lacked the horn, in which case they were rses, or else they really had the horn, in which case y were rhinoceroses

But this was not all The Secretary was loth to andon his belief in the reality of the unicorn He inted out that according to the oldest authorities the icorn was sterile The Chairman agreed, but added that number of the animals they had to consider were rile, also "Are we therefore," he said, "to regard em all as unicorns?"

The specialists in animal behaviour said that apart m their appearance, which might be deceptive, a icorn was always wild in its ways and could only be ned by a virgin dressed in white The unicorn, they d, would lay its head down in her lap and become fectly tame Against this point of view the specialists taxonomy objected that although they had often served this phenomenon, yet every time they had tained a good view of the animal it always turned out be something else, such as a dog or a gazelle and ce even a giraffe

This last observation gave rise to trouble When ch of the eleven cases was reviewed in detail, two or ee of them were clearly giraffes But the Secretary sented, he preferred to call them camelopards hen pressed to conform to the majority opinion he named firm "We are agreeing," he said, "not to call this animal a unicorn, but I see no reason why these debatable cases should be classified as giraffes I call them camelopards because they are tall like a camel and spotted like a leopard"

"Surely," said the Chairman, "that is rather an old-fashioned view? When I was a student we called all these sorts of animals camelopards, but we now know them to be giraffes The name camelopard is merely descriptive, while the name giraffe is specific one of the greatest of recent advances is the ability to give these animals specific names"

So one by one these eleven animals under review were removed from the category of unicorn Some were called horses, others giraffes (always with one dissentient voice, the Secretary's), and one was clearly a rhinoceros It was late when the twelve learned men went home to their beds, but they each had the satisfaction of knowing that never again would any of their number call a strange animal a unicorn

* * *

When I visited the Hubbards' I could never understand why their dog was hustled into the back-kitchen I never heard it bark nor look in the least aggressive It was a Borzoi, finely groomed, very long in the nose, and it always looked unspeakably bored Usually when I knocked I heard a scuffle while Mike was being dragged with skidding paws along the narrow hall to the back of the house But last Monday when I knocked I heard Mike sniffing diagnostically on the other side I inferred that the family was out and that Mr Hubbard was either too deaf to hear my knock or too immobilised by his lumbago to come to the door Accordingly I walked straight in As I anticipated, the dog came up to me and was perfectly friendly I pride myself that I understand dogs and that this sympathy is reciprocated Dogs only bite if they know you are afraid

I walked along the dark hall to the kitchen where Mr Hubbard was bending over the table holding his back with both hands At that moment I felt a sudden tug on my coat Mike had taken a grip on it "I say, call your dog off Mr Hubbard, it s got hold of my coat!"

"I can almost touch my toes," said Mr Hubbard bending with a conspicuous lack of confidence towards the floor Mike released his grip on my coat, opened his jaws and sank his teeth into my hamstrings This was very painful "Hubbard!" I screamed, "Call this cursed blood-hound away, it's got hold of my leg!" Mr Hubbard was, unhappily, fixed in flexion In this position he advanced towards us clicking his tongue in mild abuse ' Tch tch, come away, come away, now, boy, it's only the doctor"

PRESCRIBERS' NOTES III

"An advertisement is a rich man asking you to give him more money" (G K C)

or

Circles, vicious, one

The postman homeward plods his weary way,
  His shoulders lightened of his heavy load,
Thinking he ought to get a rise in pay
  With seven doctors on his daily road

Pamphlets and pictures to ensnare the eye,
  Samples their young will eat and sicken, he hoped
Blotters enow to suck the salt sea dry,
  Into the dustbin straight they go, unoped

The P.M G has heard his heartfelt cries,
  His wages raised, up must the postage go
The cost is added to the products' price
  The hopeful man thinks that will stem the flow

But when the State will pay, let money burn!
  We need not dam the ever widening stream
Yet animated bust and *stoned* urn
  Whisper, the State is you and me—and him

Epitaph

Full many a Flower is born to blush unseen
  And waste its sweetness in a bonfire's air
Full many a View of Zermatt or the spleen
  The dark unfathom'd caves of ocean bear

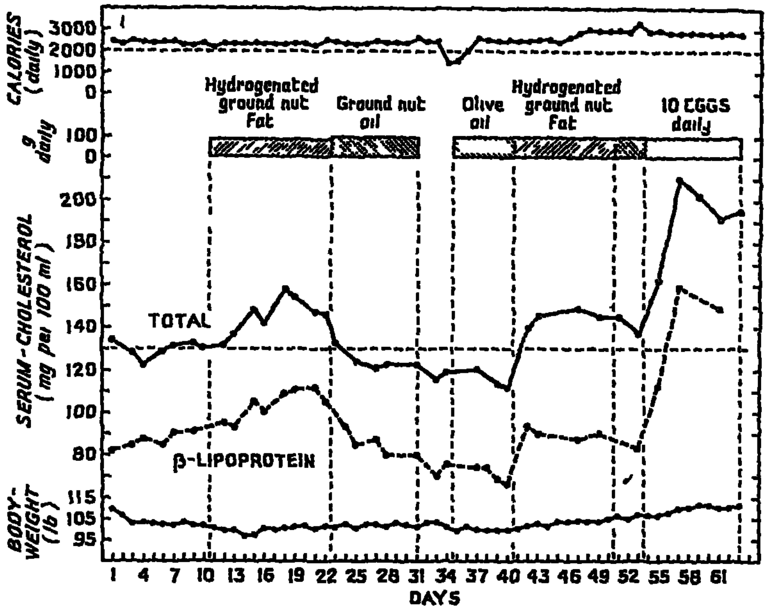

Fig 2—*A slight rise in the serum-cholesterol level of a male Bantu, aged 65, coincided with the feeding of hydrogenated ground-nut fat On switching to the natural oil the changes were reversed On re-feeding with hydrogenated fat the serum-cholesterol level rose again The amount of the rise was slight compared with that from an equivalent amount of fat as eggs The mean serum cholesterol level before the fat feeding was 129 6 ± 3 5 mg per 100 ml*

at low temperatures (Markley 1947) The saturated fraction, a palmitate stearate mixture, was removed at –20°C, and the temperature was lowered successively to –50°C and –70°C to separate off the oleic and linoleic fractions respectively Subsequently the saturated fraction and the most highly unsaturated fraction so obtained were esterified with ethyl alcohol, followed by fractional distillation in a high vacuum

The unsaturated fraction contained no sterol, determined by the Liebermann Burchard reaction by the method of Abell et al (1952) The iodine values (140–150) indicated that in using this method of fractionation we could not obtain a linoleate fraction completely free from other less unsaturated fatty acids The vitamin-E content, measured by the method of Quackenbush et al (1941), never exceeded that present in the sunflower seed oil and in most instances was far less (18–70 mg per 100 g)

Results

The effects of the short-term feeding experiments on the serum-cholesterol levels are shown in figs 1–7, which show that differences in the serum-cholesterol levels are usually paralleled by differences in the cholesterol contained in the β lipoprotein fraction

Investigation of the effects of different fat fractions on the excretion of sterols in the stools are in progress Some results are shown in figs 6 and 7 In 1 case (not illustrated) fæcal sterol during the period of administration of hydrogenated fat alone was 0 39 g daily, with the addition of the unsaturated fatty acid fraction 0 83 g daily, and after withdrawal of both supplements 0 53 g daily These values are insufficient for drawing firm conclusions

ANIMAL FATS AND VEGETABLE OILS

Changes in the serum cholesterol levels coincided with changes in the intake of fat In the first 2 cases it appeared that the findings of the inter racial survey had been confirmed, in that olive oil, representing a vegetable oil, had no effect, whereas butter and beef dripping (tallow) in equivalent amounts and beef muscle promptly raised the serum cholesterol level (fig 1) Olive oil substituted for the butter or tallow could not maintain the raised level, which remained low even when the olive oil supplement was doubled so that more than 60% of the total calories was provided by this oil

A hardened or hydrogenated ground nut fat was tried (iodine value 55) In the first case studied there was a slight but prompt rise of the serum cholesterol level When the non-hydrogenated natural oil (iodine value 89) was substituted, the serum cholesterol level fell (fig 2) The same effects were seen later in the same person and in 2 others This effect of hydrogenation influenced the design of subsequent experiments

Sunflower seed oil was fed in the presence of high serum cholesterol levels In the post hemiplegic patient the serum cholesterol level rose on the administration of 100 g of beef dripping When the intake of fat was raised to 200 g with 100 g of sunflower seed oil (iodine value 135), the serum cholesterol levels fell, only to rise again when the sunflower seed oil was withheld (fig 3) In the same volunteer the effect of ten boiled eggs was reversed when the eggs were scrambled or fried in 100 g of sunflower seed oil After a control period on 50 g of animal fat the intake of fat in the 2 European volunteers with coronary heart disease was increased to 150 g by the addition of 100 g of sunflower seed oil Immediately the serum-cholesterol levels fell (fig 4) When the sunflower seed oil was withheld and the total intake of fat thereby decreased, the serum cholesterol level returned to its original value The experiment was repeated in 1 of these 2 volunteers with 100 g of ground nut oil, which produced a similar but smaller effect

Marine Oils

Neither pilchards fried in pilchard oil (iodine value 180) nor seal oil (iodine value 166) raised the serum cholesterol levels in 3 volunteers On the contrary, the level attained during the feeding of these oils was lower than that on the fat free basic diet (fig 5) The effect of the highly unsaturated fraction segregated from pilchard

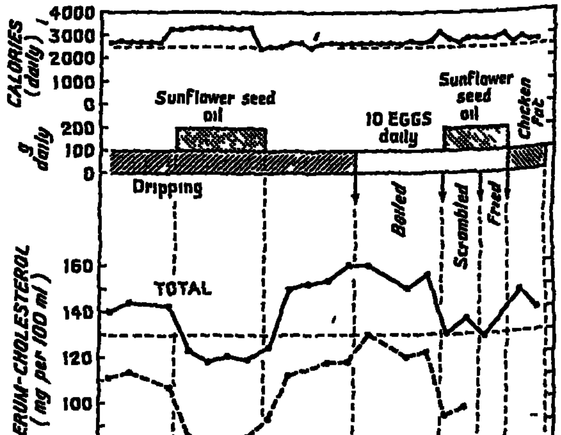

Fig 3—*The effect is shown in a male Bantu aged 37, of feeding 100 g of animal fat daily followed by an increase of the total intake of fat to 200 g by feeding equal quantities of an animal fat and a vegetable oil The egg ration was given first as ten boiled eggs daily followed by ten eggs scrambled or fried in sunflower seed oil*

Dr Peter Davey leans towards an M R C P (PATH) and then smisses it as a vain hope Since Sir Ernest Finch wrote[1] it as been generally agreed that diplomas are not badges of ntability for training as consultants Despite public suggestions[2] and informal conversations, the Royal College of hysicians so far appears to have done nothing, but perhaps r Peter Davey's hope of an M.R C P (PATH) is not, in the ng run, as vain as it appears now it is less unlikely than the lternatives

The adulation of Dr Peter Davey's last three paragraphs istresses me Of course, if he is one of the ruling class in the orld of pathology, it is understandable there never was an ligarchy yet which did not believe its rule to be for the best in he best of all possible worlds Dr Peter Davey calls it aristarchy The *Oxford English Dictionary* defines an aristarchy s a body of severe critics I am not sure that it is an appro riate title for my pathological professional acquaintances If aristarchy were intended to mean government by the élite —largely self appointed and self named—I can only cry '*A bas les aristos*' *A la lanterne*!"

It would be needless to bedevil these exchanges with personalities Perhaps some may seek to knock me off my self allotted perch and I will crave your permission to sign myself

HUMPTY-DUMPTY

LOCALISATION OF ACUTE INFLAMMATORY SWELLING

SIR,—Acute inflammatory swelling in its early stages is manifestly due to local excess of a fluid exudate rather than to cellular aggregation It is not obvious, however, why this fluid should not disperse into the surrounding tissue rather than localise as it usually does The following observation suggests that one reason for this localisation may lie in the peculiar properties and arrangement of connective tissue

Experiments with mice showed that unrestricted subcutaneous injection of water at pressures in the region of 10 cm water always resulted in a localised bleb at the injection site But when small quantities (2 c mm or so) were injected, using a fine glass needle loosely packed with minute glass spheres (ballotini), the water diffused away evenly and rapidly for a distance of 1–2 cm without any tendency to bleb formation But even in these circumstances continued infusion did not increase the area of spread Thus while small quantities of water disperse to some extent, larger quantities merely accumulate at the point of injection. It appears as though wetting of the tissue provides a barrier against the further passage of water

Previous work affords some explanation of this phenomenon Connective tissue has been considered to have an essentially lamellar constitution[3–5] The lamellæ offer considerable resistance to the passage of water across them,[6] so that water may be expected to find its way between rather than through the layers Further it has been shown that at hydrogen ion and salt levels such as exist in living tissues, the substance of the lamellæ is intensely hydrophilic[7] Free water must therefore pass through interstices which are bounded by hydrophilic material It is easy to see that such an arrangement might allow the rapid passage of small amounts of free water while blocking the passage of larger quantities completely

In-vitro studies[7] have drawn attention to a dynamic equilibrium between chemical forces which promote the taking up of free water by connective tissue and mechanical forces which lead to its extrusion It may be conjectured that ordinarily the equilibrium may allow the presence of a little free water, but injection experiments show that the addition of only a few cubic millimetres at pressures such as obtain in blood capillaries is enough to bring the localising mechanism postulated into play Since there is nothing in the composition of inflammatory exudates in general which is likely to lessen the affinity of connective tissue for water it is probable that the same mechanism operates in the early stages of all acute inflammatory processes in which interstitial connective tissue is involved

SCLERODERMA TREATED BY VERATRUM ALKALOIDS

SIR,—Assuming that in scleroderma the vascular changes are an important factor in the progress of the disability, and that the gradual diminution of blood-supply to the peripheral tissues is the cause of the muscular weakness particularly in the hands, I have treated three cases of generalised scleroderma with veratrum alkaloids in the form of 'Veriloid'

CASE 1 —A married woman, aged 54, gave a history of Raynaud's disease since 1933 This had been getting worse and she had trophic ulceration on the fingers of both hands in the winter months In 1949 she had undergone bilateral cervical and lumbar sympathectomy, which improved the peripheral circulation especially in the legs Despite the circulatory improvement she still had trophic ulcers on the fingers in cold weather and had become progressively less able to use her fingers for fine work such as sewing It was realised that she had generalised scleroderma involving the face, bib area, and both arms and hands

In December, 1951, she was started on tab veriloid 1 mg t d s, which was increased gradually to 3 mg t d s She has continued this dose steadily ever since Improvement started quite soon, her fingers became more supple, and by 1953 she could sew and knit again She has had no trophic ulcers during the past two years despite the hard winters She can now grip quite strongly The only other medicinal treatment which she has had is tab phenobarb gr ½ at night, prescribed because she complained that her nerves were bad, she was not sleeping, and she felt sick in the mornings

CASE 2 —A married woman, aged 52 was seen in February 1952, with generalised scleroderma involving the face, bib area both arms and hands, and the legs She had noticed stiffness and gradual loss of power in the hands for about two years and increasing stiffness and tightness of the skin of the face for about a year She was unable to dress herself, carry on her housework and cook or look after her family

She was started on veriloid 1 mg t d s which was gradually increased to 3 mg t d s Within two months there was definite improvement of the condition of the skin and increasing power of movement in the hands and fingers For some time now she has been able to do everything for herself, has done her cooking and housework and has walked and got about normally Since the early part of this year the dose of veriloid has been increased to 4 mg t d s, and this has hastened the improvement particularly in the hands

CASE 3 —A married woman, aged 45, who was seen on Dec 8 1955, three years ago had been operated on for repair of the pelvic floor Since then her hands and feet had been intermittently purple and stiff She had never had trouble with her circulation when she was younger During the past six months she had had dysphagia, her hands and arms had become puffy and swollen, and she had difficulty in holding things as she was unable to close her hands properly and grip On examination the patient had typical generalised scleroderma involving the face, neck, bib area, arms and hands combined with a Raynaud's condition involving the arms and legs

Treatment was started with 1 mg of veriloid three times a day On Dec 22 the dose was increased to 2 mg three times a day By Jan 26 there was much improvement in swallowing, and dysphagia was noticed only in the evenings There was also noticeable improvement in the appearance of the skin of the forearms and hands By Feb 23 the œdema of the hands had considerably diminished and the patient could grip normally despite the very cold weather Her arms were quite warm down to the wrists, although the hands were still bluish they were not unduly cold The dose of veriloid was increased to 3 mg three times a day

Of these three cases two have been treated with veriloid for four years In both cases improvement has

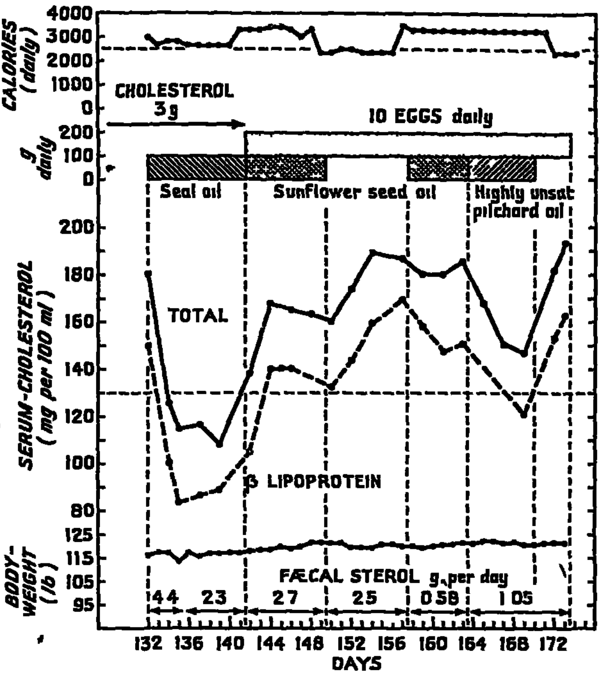

Fig 6—In same Bantu as in fig 2 a change from the saturated fraction of sunflower seed oil to seal oil was followed by a sharp drop in the serum-cholesterol level, although the intake of cholesterol was maintained Withdrawal of seal oil and addition of ten eggs daily caused a rise, which was apparently checked by giving sunflower-seed oil Highly unsaturated pilchard oil caused a sharp drop, and its withdrawal was followed by a sharp rise

We are currently investigating whether the saturated fatty-acid fraction alone, on the basic cholesterol-free diet, can raise the serum cholesterol level

OTHER DIETARY FACTORS

Vitamins

The 2 patients with scurvy had the lowest serum-cholesterol levels on admission One of them was treated with vitamin C during the first olive oil supplement, and no sudden change in the serum cholesterol level followed Later it was noticed that the cholesterol contained in the α-lipoprotein fraction may have increased, because the serum cholesterol level did not return to its value before vitamin-C therapy In the other patient with scurvy the lipoproteins were not fractionated on admission when he received vitamin C therapy, but his serum cholesterol level rose slowly and steadily during this period

In the 2 cases with vitamin B deficiency (one with beriberi and the other with pellagra) the serum cholesterol levels fluctuated under treatment with vitamin-B complex on admission Vitamin B complex administered later and to the other volunteers did not affect the serum-cholesterol levels before period of fat feeding

Protein Intake

The changes that coincided with alterations in the intake of fat took place on protein-poor and on protein rich diets Increasing or decreasing the intake of protein by adjusting the intake of casein during the control period did not affect the serum-cholesterol levels In some cases changes of this nature made a difference of more than 100 g of protein Furthermore by adjusting the intake of casein the diets in most instances could be kept isonitrogenous during feeding with supplements of different fats

Calories and Changes in Body-weight

From the figures it will be seen that only minor changes in body-weight took place in most cases A rapid gain in weight in 1 volunteer during the control period was not associated with changes in the serum cholesterol level

When the calorie intake was suddenly increased with an extra olive oil supplement in 2 non-Europeans (fig 1), and with sunflower-seed oil and marine fish and mammal oils in 2 other persons (figs 3 and 6), the serum cholesterol levels did not rise

Discussion

In these short term experiments changes in the serum cholesterol levels coincided with changes in the intake of fat The consistency of the results to date has not been affected by alterations in the protein, calorie, or vitamin intake Brief reference to some of these findings has already been made (Bronte Stewart et al 1955b, 1956) The changes appeared to be more closely related to the quality rather than the quantity of the change in intake of fat

In quantitatively equivalent amounts animal fats in the form of butter, beef dripping, beef muscle, and eggs caused a rise in serum-cholesterol levels Marine animal oils had the reverse effect on the serum cholesterol levels either when fed alone after a fat free diet or with eggs

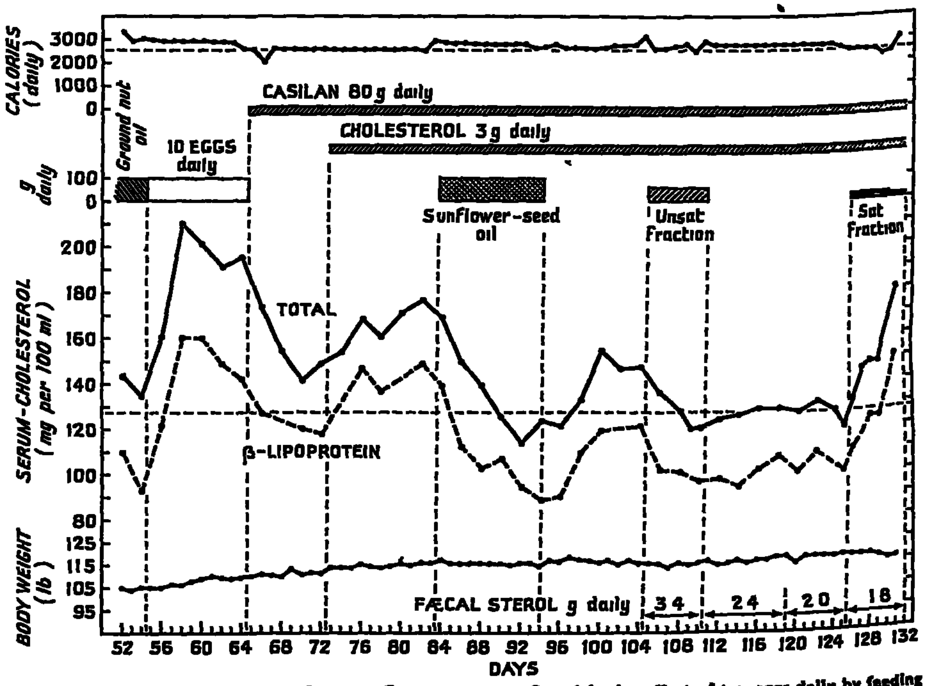

Fig 7—Attempts to reproduce, in the same Bantu as in figs 2 and 6, the effect of ten eggs daily by feeding in turn quantitatively equivalent amounts of protein, cholesterol, and fat in a qualitatively dissimilar form When an equivalent amount of cholesterol (3 g) was added to the protein, the serum-cholesterol level rose Supplementation firstly with sunflower-seed oil (100 g) and secondly with the unsaturated fraction from the same oil (60 g of ethyl linoleate) produced a sharp fall in the serum cholesterol level, which rose only when 15 g of the saturated fraction was added (at this stage the total intake of fat constituted only 8% of the total calories)

nplete, disappeared on the 13th day The temperature, ich fluctuated around 100°F, went above 101°F twice in 1st week and was normal on the 9th day Spasms were oderate until the 4th day and mild until the 12th day raldehyde needs were small The patient was discharged the 32nd day

It is hazardous to draw definite conclusions from this all series of five cases But we suggest that injected drocortisone suppresses spasms, unlike injected cortine which aggravates them although checking pyrexia tter It is our impression that, compared with oral rtisone, parenteral hydrocortisone is somewhat less fective in controlling pyrexia and somewhat more fective in controlling spasms It was not possible to mpare their effectiveness quantitatively We cannot redict which of the two will be found to give greater provement in survival rate In severe tetanus, when ormone therapy is being considered as an adjunct to utine measures, if there is dysphagia or total trismus, arenteral hydrocortisone is the best choice We have uggested[2] that cortisone given orally is converted to hydrocortisone to a greater extent than the same ormone given parenterally, which might account for he difference in their actions Now we have one more vidence for this hypothesis, in the present series njected hydrocortisone acted rather like oral cortisone nd definitely unlike injected cortisone A somewhat milar situation is well known in the treatment of rthritis, where temporary relief following intra articular ydrocortisone or oral cortisone is greater than that ollowing intra articular cortisone as free alcohol or acetate

We wish to thank Merck & Co, Inc, Rahway, New Jersey, who kindly supplied infusion concentrate and saline suspension of hydrocortisone used in the treatment of these cases

HUMAN SURVIVAL PRIZE FOR AN ESSAY

SIR,—The Medical Association for the Prevention of War (London) offers a prize of £75 for the best essay under the title "A World Approach to Human Survival and Health" It is offered as a memorial to the late John Ryle, professor of social medicine at Oxford

Earlier letters by members of the M A P W, published in your columns, have stressed the immediate urgency of action designed to reduce the risk of the outbreak of a third world war We are now concerned to emphasise the need for the steady development of a more responsible attitude of medical men and women towards the broad problem of human survival and health, and it has seemed to the committee that our best approach might be by way of a memorial to John Ryle, whose life and work were devoted so consistently to these constructive ends

Ryle's professorial interests widened from the health and disease of the individual to that of the community—not only in his own country but the world over He had always been devoted to the cause of international understanding, and between the wars he was the first president of the Medical eace Campaign He felt strongly that the doctor's humane alling gave him a special responsibility to work for the cause f peace He had friends of many races and nationalities, and he helped many individuals—members of his own profession and others—who came to this country as refugees

For Ryle the Hippocratic injunctions were binding on doctors of all countries He gave much thought to the problems facing the doctor in the modern world, and the final essay in *Changing Disciplines* is entitled "Medical Ethics and the New Humanism" While he praised the work of doctors in war—"They alone among professions have turned inhuman war to humane account and have seized opportunities to develop and improve their life saving techniques"—he warned against the dangers of being drawn into ad hoc military research, as in biological warfare He thought that doctors should insist on the right to publish their discoveries, and that the war time secrecy in the preparation of penicillin and D D T was unethical The following aptly summarises his views "The physician is, of necessity, both scientist and humanist Science and ethics, both of man's contriving, are complementary, they find their common ground in human need"

Further information may be obtained from the hon secretary of the M A P W, Dr D L Kerr, 291, Burnt Wood Lane, London, S W 17

PERFORATED ACUTE AND CHRONIC PEPTIC ULCER

SIR,—I have read with much satisfaction last week's excellent paper by Mr Hermon Taylor and Mr Warren on the conservative treatment of perforation, and I should like to congratulate them on a most valuable contribution

I am particularly gratified because their approach to the peptic-ulcer problem is based on the fundamental distinction between the acute and the chronic lesion The follow-up of their cases clearly demonstrates that the acute ulcer, which invariably heals rapidly and should therefore be left alone, never becomes chronic—a view which I have repeated for the past twenty five years

I trust that the logical approach by Mr Taylor and Mr Warren to the complications of peptic ulcer will be generally accepted and extended to hæmorrhage, which is essentially a parallel manifestation caused by the same morbid process It will save the doctor many a headache and the patient many a bellyache

SILICONE-RUBBER TUBING FOR TRANSFUSIONS

SIR,—The rubber of the standard intravenous infusion set is probably often responsible for the local thrombosis or thrombophlebitis which may follow transfusions,[1] and consequently alternative materials are being sought and tested

I have recently been using infusion sets made with silicone rubber, and it seems that this material is worthy of more extensive trial

Silicone rubber is an almost white translucent substance with a consistency similar to that of natural rubber It is unreactive with body fluids, and it is believed not to contain substances which leach out when it is in contact with water It does not melt but rapidly loses elasticity at about 500°C, and it will withstand repeated heating to 200°C without any deterioration It is an excellent insulator and will readily acquire and hold a static charge of 2000 volts, and therefore its use constitutes a potential fire risk The price is about seven times that of normal rubber

Silicone rubber is made into tubing by extrusion and a new vulcanising process which avoids contamination with any particulate matter such as talc

The tubing used was 9 mm external diameter, with a 5 mm bore, and was assembled into infusion sets of the standard blood transfusion service pattern Some of the bungs used were of normal red rubber

21 transfusions have been given with these sets ranging in duration from two to twenty hours, 8 of them lasting eight hours or more Most of the transfusions were of blood, but all the usual fluids have been given and several different needles and cannulæ used The site of the infusion was in the arm in 19 cases, and the leg in 2 cases The patients were aged 3–65 years In no case was there any local or general adverse reaction to the infusion

From such a small series no firm conclusions can be drawn, but the complete absence of reactions is encouraging The sets are pleasant to use, and it is convenient

Epidemiology

Inter-racial studies (Keys and Anderson 1954) and the drop in mortality during the German occupation of Norway (Malmros 1950, Strom and Jensen 1951) have been largely responsible for the general acceptance of the dietary-fat theory of coronary heart-disease This is always countered by reference to the fat eating Eskimo (Page 1954, Schmidt 1955) Sinclair (1953) has shown that the diet of the Eskimo consists predominantly of seal, fish, and other marine animals—an intake of fat characterised by a high content of unsaturated fatty acids—but the Eskimo diet apparently varies from area to area (Scott 1956) Fish is a major factor in the diet of the Japanese, who have one of the lowest death-rates from coronary heart disease in the world (Keys and Anderson 1954) Coronary heart disease is not prevalent in the olive oil eating Latin peoples or in primitive communities such as Africa and China, where maize, soybean, and sunflower seed allow the amount of unsaturated fatty acid to exceed that of saturated fatty acid in the diet (Tuttle 1952)

In more civilised and prosperous areas developments in animal husbandry are aimed at the greater priming of beef, improvements in egg production by battery farming, &c, and greater yields of dairy produce Moreover butter from stall-fed cows contains less iodine and linoleate than does that from cows feeding in summer pastures (Bailey 1945) More and more people are allowed the opportunity for over-indulgence in saturated fatty acids The consumption of saturated fatty acids is increasing (Fullerton 1955), often at the expense of the unsaturated fatty acids owing to the processing of natural foodstuffs Hydrogenation of vegetable oils is a recent luxury for the housewife and processed breakfast cereals are superseding porridges, with consequent loss of the natural oil contained in the germ

The decrease in mortality during the German occupation of Norway was associated not only with decreased consumption of animal fat but also with bomb damage to hydrogenation plants

The yearly increasing incidence of coronary heart-disease is seen in females as well as in males, and the death-rate in European females exceeds by far that in Bantu males (Phillips 1956) There must therefore be a factor additional to the circulating œstrogens of the female

It is as well to re emphasise that the present work has done no more than illustrate that the serum cholesterol level may be influenced by the nature of the fatty acids in the diet The results of these short-term feeding experiments agree with the findings of the inter-racial survey reported earlier (Bronte-Stewart et al 1955a), which imply that the customary dietary habits of communities may be reflected in their mean serum-cholesterol levels The evidence that the dietary fat influences the development of coronary heart disease in man, although strong, is purely circumstantial and has been derived mainly from epidemiological studies The nature of the fatty acids constituting the dietary fat may provide the basis for a better hypothesis We agree that to attribute this disease to a single cause would be a cardinal error at this stage (*Lancet* 1955) If, however, the nature of the modern diet is a major factor in the development of coronary heart-disease, there is hope that this disease may eventually be controlled and prevented

Summary

To confirm the findings of an inter racial survey in this area (Bronte Stewart et al 1955a), we fed several different fats and oils to volunteers under controlled conditions and studied the effect on the serum cholesterol levels

Animal fats and hydrogenated vegetable fat behaved differently from vegetable and marine fish and mammal oils The most likely common difference between these fats and oils is the proportion of unsaturated and saturated fatty acids in the fats and oils concerned

Sunflower seed oil and a segregated highly unsaturated fatty-acid fraction from pilchard oil have, in the persons studied, consistently depressed the serum cholesterol levels when fed alone, with a supplement of cholesterol, or with one of animal fat

The possible application of these findings is discussed, and it is suggested that certain discrepancies in the dietary-fat theory of the ætiology of coronary heart disease may be explained by variations in the nature of the fatty-acid composition of the fats concerned

This study was undertaken as part of the programme of the Research Unit in Clinical Nutrition supported in the University of Cape Town by the South African Council for Scientific and Industrial Research We wish to thank Dr Ancel Keys of the University of Minnesota, for his suggestions at the outset of these studies, and Dr W Odendaal, of the National Nutritional Research Institute, Pretoria, for the advice given later Technical and other assistance was given by Mrs C Damstra, B SC, Miss J Ethelston, B SC, Miss C Solms, Miss E Volks B SC, Mrs A Betts, Mrs E Pallett, Dr M Fewster, Mr T J Turner, Mr R Thompson, Mr D Brock, Mr G F J Schoonraad, and the staff of the Metabolism Unit We wish to thank also the directors and chief chemists of Messrs Lever Bros (S A) (Pty) Ltd, Marine Oil Refiners of Africa Ltd and the Government Guano Island authorities for the supply of fats and oils and other valuable assistance given. Finally we should like to record our gratitude to our volunteers, who consumed on many occasions malodourous oils without demur

ADDENDUM

Since submitting this paper we have seen Sinclair's (1956) stimulating analysis of the possible role of deficiency of essential fatty acids in the ætiology of atheroma, &c We cannot comment critically on his analysis here, but we are intrigued by some of the possibilities which it raises in interpretation of our own experiments with fats of differing degrees of saturation

We have also seen the detailed report of the Minnesota Arteriosclerosis Symposium The pronounced fall in serum cholesterol levels reported by Malmros and Wigand (1955) in eight cases of familial hypercholesterolæmia accompanied the institution of a diet rich in corn oil They felt these effects might possibly be due to the high essential fatty acid content of corn oil (57% linoleic acid)

These views are in line with our short-term investigations of the effects of hydrogenated and natural fats and oils which we suggest are related to their unsaturated/saturated fatty-acid content

RELEASE OF 5-HYDROXYTRYPTAMINE BY RESERPINE

SIR,—It has recently been shown that reserpine causes ı mammals and birds a conspicuous release of 5 hydroxyyptamine (5 H T) from the blood-platelets, spleen, and astro intestinal tract[1–3] A similar, although less intense, ffect has been observed on the 5-H T contained in the entral nervous system[2–4] In view of the growing nterest in reserpine in the treatment of hypertension nd mental diseases—disorders which require long-ontinued administration of the drug (0 5–5 0 mg a day) —the effect of repeated administration of small doses on ndogenous 5 H T was investigated in the rat

Four groups of 6–8 animals each were treated for thirty days ith daily intraperitoneal doses of 0 01, 0 02, 0 05, and 0 1 mg f reserpine per kg of body weight The 5 H T content of erum, spleen, and gastro intestinal tract, determined on the atropinised oestrous uterus of the rat, is shown in the accompanying table For comparison the normal 5 H T values and the values observed after a single injection of 0 1 mg of reserpine per kg of body weight are included

5 H T LEVELS IN THE RAT

Reserpine administered	5 H T content (free base)		
	Serum (μg per ml)	Spleen (μg per g)	Gastro intest tract (μg per g)
Nil	0 62	1 66	2 12
0 1 mg (single dose)	0 38	1 03	1 45
0 1 mg (30 doses)	0 04	0 11	2 15
0 05 mg (, ")	0 12	0 31	1 42
0 02 mg (,)	0 16	0 40	1 55
0 01 mg ( )	0 21	0 52	1 81

Two facts emerge clearly (1) subsequent doses of reserpine cumulate in regard to their 5 H T -releasing effect, (2) reserpine in a dosage as low as 10 μg per kg, administered over a thirty day period, produces a 60–70% reduction in the 5-H T content of blood-serum and spleen The action of reserpine on the 5-H T in the gastro-intestinal tract was less consistent

The possibility of provoking experimentally a long-continued low blood-level of 5 H T is of obvious interest, especially in respect to the problem of the biological significance of 5 H T Further investigations are needed to decide whether the results obtained in the rat apply to man If this were so, the question would arise whether the low blood-level of 5 H T produced and maintained by reserpine is advantageous in treatment or, on the contrary, an undesired, and perhaps dangerous, side effect

OBSERVER ERROR

SIR,—In 1949 during the spring semester at the University of California, 1800 new students were enrolled Radiographs of their chests on 70 mm films were interpreted by a panel of observers so that each film was read ten times 254 films thus brought to light were suspect —that is, contained abnormal shadows All of the 254 were repeated on 14 × 17 in films and 30 were unanimously regarded as requiring further clinical study These 30 were called positive No reader selected all of the 30 The most successful selected 22 and the least successful only 17 On an average, readers missed 32 2% of positives These results published by Yerushalmy et al,[1] have received widespread notice

In January, 1954, you, Sir discussed[2] the lack of conformity in opinions on X ray films, and you stated that the significance of this lack of conformity in general medicine was probably very small but that there were times when it was very important You added "In mass radiography surveys the films are read only once, and even though the greatest possible care be taken, it is inevitable that some patients will be given a clean bill of health to which they are not entitled Their number (which may amount to 30% of all positive cases) can be significantly reduced if the films are read again by a second independent observer" Much of the evidence for this statement was based on Yerushalmy's paper and the results of this state of affairs amongst Californian students were assumed to apply to all mass X ray surveys in Britain

TABLE I—FOLLOW UP OF 30 POSITIVE FILMS (YERUSHALMY ET AL)

Activity status	No of patients	Total readings	Positive readings	Negative readings	% overlooked
Active total	7	70	44	26	37 1
(a) Bacteriologically positive	4	40	23	17	42 5
(b) Clinically active	3	30	21	9	30
Inactive	23	230	161	69	30
Total positive	30	300	205	95	31 7

Yerushalmy et al go on to give a highly interesting follow up of the 30 positive cases which is summarised in table I, taken from their paper

The day your leader appeared, the *Manchester Guardian*[3] reported 'Mass Radiography Fallible Double Check Urged One third of all people examined by mass miniature radiography with lung disease are liable to be mistakenly given a clean bill of health" Thus, a survey in an American university which revealed only 4 bacteriologically positive cases and 3 clinical ones became the basis of a half column report in a national newspaper about British miniature radiography

More recently[4] you said "It is quite clear that a single observer attempting to pick out cases of pulmonary tuberculosis from a largely normal population is likely to overlook about a quarter of the abnormal films" You do not say whether these abnormal films are significant of active disease, but that is probably what is meant, for later you point out that "this proportion has been remarkably constant in repeated trials in several countries", and you go on to quote Groth Petersen and Moller, who have shown that of the cases missed at a single reading, 86% were sputum positive 35% were of bilateral disease, and in 15% there were cavities

These results are so conspicuously different that it seems highly unwise to apply surveys in other countries to Britain

During 1954 we decided to double check the readings of 10,000 miniature films The method was as follows

The miniature films were first read by the director of the unit concerned and a list of persons requiring recall for large

severe hæmorrhagic diathesis developed followed by septicæmia due to *Escherichia coli* and *Pseudomonas pyocyanea*. Electrocardiography showed pronounced myocarditis. Bone-marrow biopsy revealed severe damage to the blood-forming cells "presumably due to some drug or other." A few days after the anæsthesia had been discontinued signs of remission developed in the bone-marrow, yet on the twenty-ninth day the boy died from cardiac insufficiency and septicæmia.

When we reviewed the case-histories of the first 2 patients, who had recovered, it became clear that they also had shown signs of hæmatological complications. The 1st, a boy aged 10 years, had thrombocytopenia, hæmaturia, and retinal hæmorrhage on the fourteenth day of treatment. In the 2nd case, that of a boy aged 11 years, between the sixth and tenth days in hospital the leucocyte count fell from 12,500 to 2200 per c.mm. Treatment was discontinued on the twelfth day, and the blood was not examined again.

The 4th patient had moderately severe tetanus and hæmatological complications did not appear.

In March, 1955, a 5th patient, a woman aged 53, was admitted with severe tetanus.

Very early after admission tracheotomy had to be done. After the operation she was treated according to the principles previously outlined, including anæsthesia with nitrous oxide and oxygen.

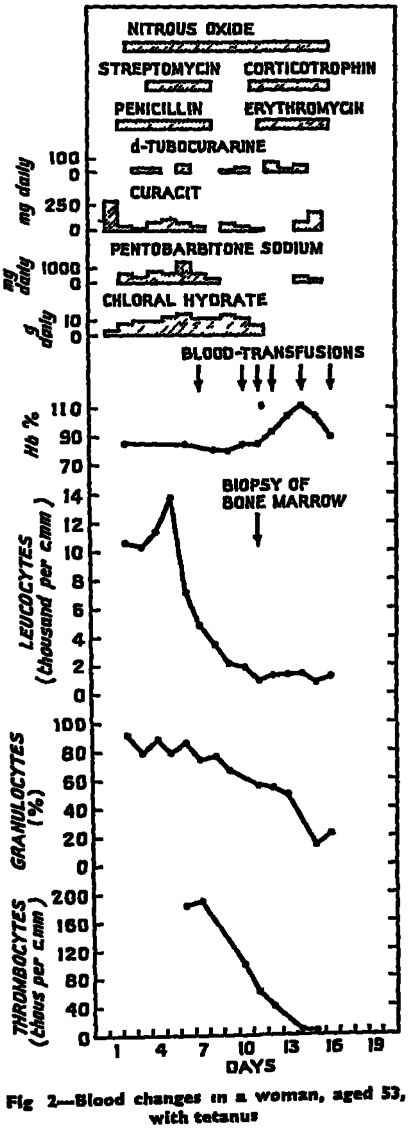

Fig 2—Blood changes in a woman, aged 53, with tetanus

CHANGES IN PERIPHERAL BLOOD IN RELATION TO DRUGS USED IN PATIENTS WITH SEVERE TETANUS

Treatment	Granulocytopenia and/or thrombocytopenia	No hæmatological complications
Chloral hydrate	3	7
Pentobarbitone sodium	5	5
Phenemal sodium	0	1
Pethidine	0	1
d-Tubocurarine	3	0
Bromethol	0	1
'Curacit'	1	0
'Largactil'	1	0
Continuous nitrous oxide	6	0

Fig. 2 shows how the tetanus gradually subsided and the dosage of sedatives was reduced considerably. Blood counts were made daily and already on the fifth day a pronounced granulopenia was observed, and this was soon followed by thrombocytopenia.

Pentobarbitone was suspected of having depressed the bone marrow. On the eleventh day, therefore, it was withheld. This did not have any effect. On the same day a bone marrow biopsy showed "Hypoplastic bone marrow with reduced erythropoiesis of megaloblastic type, granulopoiesis with a pronounced shift to the left, and numerous myeloid cells of undetermined character." The pathologist concluded that all the observed changes might be due to severe drug allergy.

Treatment with large doses of vitamin B_{12} was instituted on the thirteenth day, but no increase of reticulocytes or other sign of remission was observed. In all other respects the treatment remained unchanged. Septicæmia caused by *Esch. coli* now developed, and the patient died on the sixteenth day with signs of severe hæmorrhagic diathesis. Post-mortem specimens of bone marrow revealed "pronounced atrophy with greatly reduced or probably totally abolished myelopoiesis."

Gormsen (1955) published a case of severe tetanus showing agranulocytosis and thrombocytopenia in a boy treated by prolonged anæsthesia with nitrous oxide and oxygen, chlorpromazine, and curare. In this case also a reduced number of leucocytes in the peripheral blood was observed on the fifth day of treatment, followed by a decrease in the number of thrombocytes. Gormsen presumed that the hæmatological changes were due to the large doses of curare.

It thus became clear that the complex treatment to which our patients with tetanus had been submitted produced with great regularity signs of acute depression of the bone-marrow at the end of the first week of treatment. What could the cause be? Did extremely severe tetanus cause bone marrow damage which had hitherto been unobserved because formerly these patients died? Or was it due to the heavy dosage of pentobarbitone? Or chloral hydrate used for several weeks? Could nitrous oxide anæsthesia continued for many days be responsible despite the accepted innocuousness of this widely used anæsthetic agent? Or could the hæmatological complications be traced back to the large doses of curare used over several weeks?

In an attempt to detect the cause we have studied 13 cases of tetanus, most of them of short incubation and rapid evolution.

In the accompanying table the cases have been divided into two groups with and without granulocytopenia and thrombocytopenia. In the first group all the patients underwent tracheotomy, but in the second group only 6 of 8. This fact shows that the cases in group 1 were more severe than those in group 2. The difference, however, is not pronounced; hence the conclusion that the hæmatological complications could be due to the severity of the tetanus seems unlikely. Nor were signs of a hyperimmunising effect observed with abnormal hæmolysis, and electrophoresis did not reveal an increase of the gamma globulin fraction of the serum proteins.

The possibility remained that one or other of the drugs used was responsible.

The table shows that only nitrous oxide was a common factor in the treatment of all the patients who presented blood changes. The use of the other drugs—e.g., pentobarbitone—was equally distributed in both groups, or else they were used only sporadically. Suspicion was thus directed towards the anæsthesia, and the fact that the hæmatological complications regularly appeared from five to seven days after its introduction further incriminated the nitrous oxide.

The extensive literature on nitrous oxide contains no information about toxic effects on the bone marrow. This anæsthetic, in fact, is considered completely using two ordinary plaster bandages The ordinary bandage was not strong enough Satisfactory body-casts have been made and tube plasters for patients with knee-joint lesions, the casts in each case being lighter yet as strong as or stronger than conventional plasters

Similar results have been reported by Maudsley,[3] Arden and Ward,[4] and Sayle-Creer [5]

I am indebted to Messrs Smith & Nephew Ltd for their assistance in these experiments

GIANT HYPERTROPHIC GASTRITIS

SIR,—Dr Einan Williams describes (April 7) a case of what is undoubtedly Menetrier's *polyadenome en nappe*, but Dr Williams describes the lesion under the title "giant hypertrophic gastritis" and makes it quite clear that he considers it to have an inflammatory origin It is our view [5] that the condition described by Ménétrier was not primarily an inflammatory one but one for which the name "giant rugal hypertrophy" is more apt The term "chronic hypertrophic gastritis" has a different connotation, as pointed out by Dr Williams This is very much more common than "giant rugal hypertrophy," is mainly a gastroscopist's diagnosis, and is believed by many to be physiological

SCOTLAND'S LEAD

SIR,—In your issue of March 24 you discuss the policy on joint training in hospital and general practice agreed between the Joint Consultants' Committee (Scotland), the General Medical Services Subcommittee (Scotland), and the Department of Health for Scotland

The initiative in such joint training was taken by the Northern Regional Hospital Board (Scotland) with the cooperation of the local executive council early in 1952,[6] and the scheme has been operated since then This scheme, which has provided experience in the various specialties in turn (in the grade of senior house officer) with parallel training in general practice, has proved most successful The proposed "new" scheme is, in essentials, the same

JAMES SOUTH
Inverness Formerly chairman Northern Regional Hospital Board

DEATH UNDER CHARLES II

SIR,—In his interesting note (March 31) Dr Hall confesses to being puzzled by the term "flox" He writes "Three people died of 'flox,' which apart from the obvious mis spelling has me puzzled"

"Flox" is defined in Charles Creighton's *History of Epidemics in Britain* (Cambridge, 1894, vol 2, p 436, note 2), which states

"The original heading in the Bills of Mortality was 'flox and smallpox' 'Flox' meant flux or confluent smallpox which was so distinguished, as if in kind, from the ordinary discrete form seldom fatal Huxham, in 1725, *Phil Trans* xxxiii, 379, still used these terms 'When the pustules broke out in less than twenty four hours from the seizure, they were always of the flux kind, as is commonly observed Pocks which at first were distinct would flux together during suppuration' Dover, *Physician's Legacy*, 1732, p 101, has 'the flux smallpox, or variolae confluentes,' as one of the varieties and again, pustules 'fluxing in some parts, in others distinct'"

STREPTOKINASE AND STREPTODORNASE IN INFLAMMATORY ŒDEMA

SIR,—Good results have been reported [1] with intramuscular injections of streptokinase and streptodornase in the treatment of inflammatory œdema This action was attributed to the dispersal of fibrinous clots in the intra-tissue spaces around the site of infection To avoid the very unpleasant local application of the drug, and to study the general action of streptokinase and streptodornase, I gave intramuscular gluteal injections to 45 patients with acute inflammatory and traumatic œdema and 18 patients with chronic infiltrations

The patients' ages ranged from 18 to 54 years They were chosen because they had widespread acute œdema or extensive hard infiltration without fluctuation and reddening of the skin

After trying small and large doses I concluded that the best results were obtained by giving 2000 units of streptokinase and 500 units of streptodornase per dose The injections were usually repeated every second day, and 2 to 4 injections were generally sufficient In most acute cases penicillin was given as well, patients with tuberculous cervical lymphadenitis had streptomycin and isoniazid

The results in patients with acute œdema are shown in the accompanying table Very recent infiltrations sometimes receded after a single injection, usually without penicillin Infiltrations present for several days required 2 or 3 injections The softening infiltrations opened spontaneously within twenty four hours, and œdema subsided rapidly

With fresh hæmatomas the results were distinctly worse, and in patients with subacute infiltrations there were visible results in a few cases only In chronic œdema there was no definite improvement

Occasionally the injection of the enzymes provoked a strong reaction, especially in acute inflammatory conditions The reaction appeared three to six hours after the injection The features were fever, joint pains, headaches, epigastric pain and nausea, tachycardia, and increase in blood pressure The symptoms usually disappeared in six to twelve hours These reactions also occurred in healthy controls, so they may be an allergic response to protein in the enzymes The symptoms pointed to a transient, intense stimulation of the sympathetic system, and the administration of a sympathetic blocking drug (e g, dihydroergotamine) relieved the symptoms in some cases

Because of the possibility of a reaction, this treatment should not be used in persons with cardiovascular disease, in old persons, and in those with a history of tuberculosis

TREATMENT OF ACUTE INFLAMMATION WITH INTRAMUSCULAR STREPTOKINASE AND STREPTODORNASE

Condition	No of patients	Disappearance of œdema and infiltration or rapid softening and rupture				Doubtful result (14–28 days)	No improvement
		In 24 hours (1 injection)	In 24–72 hours (1–3 injections)	In 3–7 days (2–4 injections)	In 7–14 days (4–5 injections)

coagulating, or to relieve the pain When the needle is not at work, there is a trolley with more doses to be taken by mouth

One of the results of this continual attention is immense tiredness The very sight of a nurse with a glass or syringe is exhausting It is bad enough having to be in a ward with perhaps 30–50 other patients (although this has its advantages in taking one's mind off oneself), but any brief nap is interrupted ruthlessly, so that the patient gradually becomes aware that this is not a hospital at all, but a factory in which certain procedures are performed every few minutes, regardless of circumstance

Though I have heard it said, proudly, that "the days when one walked on tiptoe if someone was ill" are gone forever, it is not the nurses who are at fault They do not invent these new methods They obey orders and many of them do so with all the gentleness and grace they can summon to aid them in their lives of devotion and service But I do suggest that a new callousness is creeping into our hospitals, and I think that certain practices should be frequently reviewed in the hope of eliminating the distress and discomfort they cause In particular, since it is mainly the old who have to submit to them, I would like very senior doctors to be consulted And most of all, I would like the human being, rather than the human being's ailment to have top priority—however unscientific that may sound

A PATIENT'S FRIEND

MALARIA AND THE THAMES

SIR,—Almost the whole of the initial historical section of this paper (*Lancet*, April 14) has been borrowed from a paper of mine,[1] sometimes word-for-word, sometimes with so little care that mistakes have been introduced that cannot be passed uncorrected In his *Ecclesiastical History* the Venerable Bede never mentions the *lencten adl* ("spring ill," i e, malaria), nor does he "draw attention" to any "prevalent" fever He refers only to a single case of fever where the sufferer went and sat by St Oswald's tomb, so that the attack did not return either on the second or third day, or subsequently All that interested Bede was the miracle The point of my story was, that the translator of Bede's Latin, presumably King Alfred, in turning this passage into Anglo-Saxon did not render Bede's vague "*febris*" by an A-S equivalent, but replaced it by the specific "*lencten adl*", thus naming the disease malaria, which probably it was Shakespeare did not use "ague" in *Macbeth* "mistakenly", this old name for typhus still lingered on in his day, and survived still longer in Ireland Samuel Butler, Charles II's favourite poet, is called "the essayist"—here perhaps he is confused with Samuel (*Erewhon*) Butler Horace Walpole was not the first person to employ the word malaria, he was merely the first, so far as is known, to introduce this existing Italian term into English He was not writing to Thomas Gray, and Gray was not in London—he was with Walpole in Italy The letter in question was not dated "1840" but July 5, 1740, and was addressed to the Hon H S Conway In it Walpole explains that he has left Rome because of the horrid thing called the mal'aria, and adds, "I do not care for being killed so far from Christian burial!" And, finally, the author of the *Elegy* did not spell his surname "Grey"

CERVICAL VERTIGO

SIR,—I have read with great interest the article by Dr Ryan and Dr Cope (Dec 31) I fully agree that vertigo is often unconnected with disorder of the inner ear.

In 1940 I described[1] a disorder of the neck muscles—especially trapezii—which is often associated with giddiness, notably on movement of the head, and sometimes with occipital headache I have since again drawn attention to the frequency of this form of giddiness[2] which can be rapidly cured by treatment of the muscular lesion This remarkable fact is explained by the experimental finding[3] that the neck muscles, largely concerned with equilibrium and maintaining the posture of the head have a nervous connection with the labyrinth It is obvious that the position of the head, relative to that of the body determined by the tonus of the neck muscles serves as do the eyes the function of equilibrium

TRANSPORTING PATIENTS WITH POLIOMYELITIS AND BULBAR OR RESPIRATORY PARALYSIS

SIR,—Last summer we supervised the transport of 12 patients with severe acute poliomyelitis to the regional poliomyelitis unit at Rush Green Hospital, Romford, Essex These patients had either bulbar paralysis or paralysis of diaphragm and/or intercostal muscles, or combined bulbar and respiratory paralysis

The ambulances used were of the usual type in service in Essex, except when transporting a patient in a complete "iron lung" The equipment carried included all the instruments, drugs, and endotracheal tubes necessary for tracheotomy under general or local anæsthesia, positive-pressure apparatus, consisting of an Oxford inflating bellows and a Beaver Mark I or II machine, portable suction apparatus, oxygen cylinders, bronchoscope laryngoscope, torches, and spatulæ This equipment is fairly compact and takes up little space in an ambulance or police car The distances covered varied from 12 to 30 miles

Bulbar Paralysis

These cases were either "dry" or "wet"—that is, with partial or complete pharyngeal paralysis, this factor determining the degree of "pooling" of saliva and mucus in the pharynx and larynx

"Dry" bulbar cases were not difficult or worrying to transport The patients were conveyed prone with the head turned to one side, a few pillows placed under the abdomen facilitating postural drainage on the ambulance stretcher bed, secretions ran out of the mouth easily since the head was inclined downwards This is the position adopted for patients immediately after tonsillectomy, except that in poliomyelitis cases the tilt often needs to be steeper The patients were given swabs and encouraged to spit out their saliva, and suction was usually not necessary to maintain a clear airway

"Wet" bulbar cases with complete pharyngeal paralysis were often very irritable and, because of severe headache, were reluctant to remain in the safe prone position with head inclined downwards Vomiting was common, partly because the frequent suction necessary irritated the pharyngeal wall Torch spatula, and suction apparatus were the essential instruments during the journey with these cases A stethoscope was invaluable for listening over the trachea to check that the airway was clear

Respiratory Involvement

When the respiratory paralysis was slight (e g, some intercostal weakness) there was no difficulty in transporting the patient in an ordinary ambulance Respiration was

The unchanged state of cases 3–6 may not be an entirely negative result Certainly in cases 3 and 4 a further deterioration as a result of renal disease was to be expected, even within the limited follow up

Control of Diabetes

It is difficult to calculate, except in general terms, any change in the ease with which the diabetes was controlled These patients after operation were attending frequently and were under close observation, hence adjustments of insulin dosage or of diet were readily made There did not appear to be any significant difference in average blood sugar level, total glycosuria daily, or incidence of hypoglycæmia after the operation, except in case 5, who achieved an average blood sugar level of 150 mg per 100 ml and a daily output of less than 5 g of glucose on the same dosage of insulin—16 units daily Possibly the improvement was entirely due to improved care with diet The patient has had one attack of insulin coma, due to delay of a meal, since operation This is the only major episode of hypoglycæmia in the whole series

Insulin Dosage

In Wortham and Headstream's (1953, 1954) series the insulin dosage after adrenalectomy was two thirds of that before operation After hypophysectomy in Olivecrona's series (Luft et al 1955) the average was from a quarter to a third of the preoperative dosage In the present series there was no significant reduction in insulin dosage This may be due to the use of a comparatively large maintenance dosage of cortisone (50 mg) The possibility of supplementing a lower dosage with deoxycortone acetate was considered but rejected Luft et al (1955) no longer use deoxycortone acetate, because of its unfavourable effect on damaged blood-vessels

Retinopathy

In case 2 vitreous hæmorrhages, which were taking place at least once a fortnight, have ceased, there being no recurrence since the operation The appearance of retinitis proliferans persists, but the visual acuity in each eye is 6/6 In cases 3 and 4 there has been no detectable change in the retinopathy, but, since massive vitreous hæmorrhage had already obscured the fundus, it is impossible to be certain

In case 5 fresh vitreous hæmorrhage recurred two months after the operation and was followed by glaucoma with total loss of vision in the left eye Fortunately the right eye, amblyopic because of a squint, was only slightly affected by retinopathy, and the visual acuity is slowly improving Case 6 has been followed for only four months, and the absence of change is not significant

Albuminuria

Apart from case 1, already in advanced renal failure, cases 3 and 4 have shown no sustained improvement in daily albuminuria Six months after the operation both showed a significant decrease—from 5 to 2 g and from 2 to 0 g —but three months later there had been a return to the preoperative levels

Blood pressure

In cases 3 and 4 there was no reason to doubt that the hypertension was renal in origin, the reduction in blood pressure cannot be considered significant after so short a follow up In case 5 a rising blood pressure had been noted for seven years, and a diagnosis of essential hypertension was accepted

Discussion

If these results are considered in conjun [illegible] those of Wortham and Headstream (1953, 195 [illegible] conclusions may be advanced in spite of the smal [illegible] of patients, they are those which common sense s [illegible]

(1) The operative mortality of total adrenalectomy in patients with diabetic vascular disease not having renal failure is negligible

(2) Maintenance with cortisone after total adrenalectomy is simple

(3) The general health is not made worse by total adrenalectomy

(4) Control of the diabetes is unaffected by total adrenalectomy

(5) Retinopathy and renal damage may be halted at an early stage, this cannot be established until after a longer follow up Advanced retinopathy is not altered, and renal failure, if established, is accelerated

Selection of Material

It is now generally agreed that the most urgent clinical problem in diabetes is the vascular disease which seems to develop inevitably if the patient lives sufficiently long Those whose diabetes starts after the age of 50 may live to old age without apparent acceleration of arteria degeneration, but the young are condemned to certain death from a characteristic disorder of small vessels, i other hazards of diabetes are avoided (Mirsky 1946) Now that these hazards are becoming relatively unimportant, the patient with advancing vascular disease is becoming rapidly more common That vascular disease both atherosclerosis and capillary damage, is more common in diabetics than in non diabetics is the finding of all substantial inquiries both in living and in dead subjects (Liebow et al 1955, Bell 1950) Capillary lesions are seen with increasing frequency the longer diabetes persists, but atherosclerosis, though abnormally common, seems not to be related to the duration of diabetes (Mirsky 1946)

Atherosclerosis and diabetic "angiopathy," as Lundbæk (1954) has named the capillary disease of diabetes, may be considered separately, it is not to be assumed too readily that they are unrelated, for we have to remember that the angiopathy can be detected in the retina at a very early stage and in the kidney by inference from examination of the urine, whereas atherosclerosis can only be diagnosed in life by rather gross clinical signs At present there is no conclusive evidence that the arterial lesions differ from those of patients without diabetes On the other hand, the picture of diabetic angiopathy is gaining definition The histological changes in the retina described by Ballantyne and Loewenstein (1943) remain specific for diabetes Ashton (1951) found similar, though not identical, changes in non diabetic eyes, but the over-all picture is entirely individual The same is true of the renal disorder In view of the tendency of pathologists to disagree, the relation of the nodular lesions in the glomeruli to diabetes has been accepted to a remarkable extent (Bell 1950) Apart from other resemblances, the staining reactions of the hyaline material with the periodic acid stain suggest that the lesions in the kidney and the retina are manifestations of a single disorder, and studies of necropsy material (McManus 1950) confirm that they coexist in all fatal cases It is this angiopathy, believed to be a specific complication of diabetes, which is under consideration for possible relief by adrenalectomy Perhaps the lesions occur elsewhere than in the retina and kidney, but it is in these sites that arise the symptoms which justify a desperate remedy To make a firm criterion for such an interference it is necessary first to consider the clinical course of retinopathy and nephropathy in the absence of specific [illegible]ent

Parliament

The Budget

SYMPTOMS of severe inflation were described by Mr Harold Macmillan, Chancellor of the Exchequer, in his Budget speech last Tuesday The few new measures by which he proposes to counter this are directed mainly towards encouraging saving and curbing industrial investment There are to be a new issue of National Savings Certificates, yielding over 4% tax-free in a seven-year period an increase in the interest on Defence Bonds from 4% to 4½%, and for the first time premium bonds involving tax-free prizes The bread subsidy is to be terminated in September. The Chancellor announced an immediate increase in tax of 2*d* for 20 cigarettes, with corresponding increases for other tobacco preparations His one or two concessions include an increase of 2*s* in the family allowance for a third and subsequent children and a proposal to give effect to a recommendation of the Millard-Tucker Committee, so that the self-employed, including professional men in practice, shall gain relief from income-tax and surtax on premiums to buy a deferred annuity on retirement Income-tax is to be unchanged

Shortage of Nurses in Hospitals

On April 11 in a debate on the adjournment Dr A D D Broughton raised the question of the shortage of nurses in hospitals Though there were now more nurses than at the start of the National Health Service there were still not enough and their distribution was uneven Why were not more women entering the profession, why were so many leaving before completing their training, why were so many leaving hospital after completing their training? In recruitment the nursing profession faced the competing claims of other professions, of business, and of industry Even in hospitals themselves, other departments drew girls away from nursing and provided interesting work with regular hours and good pay

Turning to wastage during training, he asked for a review of the curriculum In 1947 the Working Party had suggested two years' basic training, but this had still not been implemented Many trained nurses, he continued, were drawn from the hospitals by local authorities and industrial firms From a national point of view first-class women were being wasted on work which could sometimes be done by capable women trained in first-aid and home-nursing When things were going well it was sensible to leave matters in the hands of the Whitley Council and the General Nursing Council, but when more than 16,000 beds were closed through lack of nursing staff it was time (Dr Broughton thought) for the Minister himself to examine the whole problem

Miss Patricia Hornsby-Smith, parliamentary secretary to the Ministry of Health, agreed that there was no reason for complacency, but she was concerned that in a year when the Government were doing their utmost to stimulate recruiting, particularly for mental nurses, the picture should not be painted in the wrong colours There had been substantial and steady progress since the National Health Service came into being The total nursing staff in hospitals in 1948 numbered 117,000 full-time, in 1955 it was 143,000 There were 20 000 part-time nurses in 1948 now there were 32,000 There were 44 000 full-time trained nurses in 1948, now there were 55,000 In 1948 there were 6000 part-trained nurses against 12,000 at present In 1948 the number of enrolled student nurses was 42 000 and in 1955 it was 48 000 Pupil assistant nurses had increased from 2600 in 1948 to 4000 in 1955 On the general nursing side, with a few local bad patches, the number of students was fully adequate for a continuing and steady increase in the number of nurses The rate of entry in general nursing was over the whole country satisfactory, but it was still inadequate on the mental side She was sure that the new scheme of training allowances (see p 518) would stimulate recruiting

Clean Air Council

The Clean Air Bill was considered on report in the House of Commons on April 10 On the motion of Mr Duncan Sandys, Minister of Housing and Local Government a new clause was agreed to providing for the appointment of a consultative council, to be called the Clean Air Council of which the Minister will be chairman, to keep under review the progress made in abating the pollution of the air and to obtain the advice of people with special knowledge experience or responsibility in regard to the prevention of air-pollution The clause provides for the appointment of a similar council for Scotland

QUESTION TIME

Smoking and Lung Cancer

Lieut -Colonel Marcus Lipton asked the Minister what information he would now publish on the connection between smoking and lung cancer —Mr Turton replied I am not yet ready to add to the answer I gave on March 26 Lieut - Colonel Lipton Why is the Minister so hesitant about following the advice of his own medical advisory committee and the Central Health Services Council over a month ago that the public should be informed of the known facts will he give an assurance that this inexplicable delay on the part of the Government is not prompted by financial considerations ?—Mr Turton It is for me to see what are the known facts compared with what they were when my predecessor made his statement in February, 1954,

Whitley Council Machinery

Replying to a question Mr R H Turton, Minister of Health, said that he and the Secretary of State for Scotland had accepted the Guillebaud Committee s recommendations on Whitley Council machinery The management and staff sides of the councils were being invited to explore the methods used in other large scale undertakings to introduce flexibility into national agreements The management sides were being asked to propose alterations in the constitutions of the councils that would add 3 hospital representatives to each To facilitate this he and the Secretary of State for Scotland were willing for the representation of their departments to be reduced by the same number on all the councils except the optical and pharmaceutical where there were special departmental interests The views of the management sides were being sought on the question of consultation with hospital authorities, but it would be made clear that in the opinion of the Government any arrangements that might cause further delay in the reaching of settlements should not be contemplated The attention of both management and staff sides was being drawn to what the Guillebaud Committee had said about delays Negotiations on pay and conditions of service necessarily took time but the Government were confident that all concerned would do their utmost to ensure that there were no avoidable delays

Tooth-paste Advertisements

Replying to a question Mr Derek Walker Smith, parliamentary secretary to the Board of Trade, said that after taking expert advice the Minister had come to the conclusion that the available evidence dealing with false claims by tooth paste manufacturers would not support a prosecution under the Merchandise Marks Acts The British Dental Association deprecated the form of the advertisement which it thought might be the result of inadequate evidence, but it was not prepared to say that the claim was false

N.H S Estimates

Replying to a question Miss Hornsby Smith said that £2½ million was included in the estimate for N.H.S expenditure in 1956–57 to cover increases in salaries and wages already agreed or still under negotiation The new award for nursing staff would require a supplementary estimate

Unemployed Doctors

Dr D Johnson asked the Minister whether he was aware that there were 35 doctors in receipt of unemployment benefit on March 19, 1956 what steps he was taking to find opportunities for employment for them in the National Health Service whether he was aware of the existence of a permanent reservoir of unemployed or underemployed doctors unable to find work under the National Health Service ?—Miss Hornsby-Smith replied It is estimated that there are 53,000 doctors in active employment in Great Britain, the proportion receiving unemployment benefit is therefore extremely small. Every effort is made to bring vacant posts to notice A committee had been appointed to inquire into future requirements for doctors and students

The unchanged state of cases 3–6 may not be an entirely negative result Certainly in cases 3 and 4 a further deterioration as a result of renal disease was to be expected, even within the limited follow-up

Control of Diabetes

It is difficult to calculate, except in general terms, any change in the ease with which the diabetes was controlled These patients after operation were attending frequently and were under close observation, hence adjustments of insulin dosage or of diet were readily made There did not appear to be any significant difference in average blood sugar level, total glycosuria daily, or incidence of hypoglycæmia after the operation, except in case 5, who achieved an average blood sugar level of 150 mg per 100 ml and a daily output of less than 5 g of glucose on the same dosage of insulin—16 units daily Possibly the improvement was entirely due to improved care with diet The patient has had one attack of insulin coma, due to delay of a meal, since operation This is the only major episode of hypoglycæmia in the whole series

Insulin Dosage

In Wortham and Headstream's (1953, 1954) series the insulin dosage after adrenalectomy was two thirds of that before operation After hypophysectomy in Olivecrona's series (Luft et al 1955) the average was from a quarter to a third of the preoperative dosage In the present series there was no significant reduction in insulin dosage This may be due to the use of a comparatively large maintenance dosage of cortisone (50 mg) The possibility of supplementing a lower dosage with deoxycortone acetate was considered but rejected Luft et al (1955) no longer use deoxycortone acetate, because of its unfavourable effect on damaged blood-vessels

Retinopathy

In case 2 vitreous hæmorrhages, which were taking place at least once a fortnight, have ceased, there being no recurrence since the operation The appearance of retinitis proliferans persists, but the visual acuity in each eye is 6/6 In cases 3 and 4 there has been no detectable change in the retinopathy, but, since massive vitreous hæmorrhage had already obscured the fundus, it is impossible to be certain

In case 5 fresh vitreous hæmorrhage recurred two months after the operation and was followed by glaucoma with total loss of vision in the left eye Fortunately the right eye, amblyopic because of a squint, was only slightly affected by retinopathy, and the visual acuity is slowly improving Case 6 has been followed for only four months, and the absence of change is not significant

Albuminuria

Apart from case 1, already in advanced renal failure, cases 3 and 4 have shown no sustained improvement in daily albuminuria Six months after the operation both showed a significant decrease—from 5 to 2 g and from 2 to 0 g—but three months later there had been a return to the preoperative levels

Blood-pressure

In cases 3 and 4 there was no reason to doubt that the hypertension was renal in origin, the reduction in blood-pressure cannot be considered significant after so short a follow up In case 5 a rising blood pressure had been noted for seven years, and a diagnosis of essential hypertension was accepted

Discussion

If these results are considered in conjunction with those of Wortham and Headstream (1953, 1954), certain conclusions may be advanced in spite of the small number of patients, they are those which common sense suggests

(1) The operative mortality of total adrenalectomy in patients with diabetic vascular disease not having renal failure is negligible

(2) Maintenance with cortisone after total adrenalectomy is simple

(3) The general health is not made worse by total adrenalectomy

(4) Control of the diabetes is unaffected by total adrenalectomy

(5) Retinopathy and renal damage may be halted at an early stage, this cannot be established until after a longer follow up Advanced retinopathy is not altered, and renal failure, if established, is accelerated

Selection of Material

It is now generally agreed that the most urgent clinical problem in diabetes is the vascular disease which seems to develop inevitably if the patient lives sufficiently long Those whose diabetes starts after the age of 50 may live to old age without apparent acceleration of arterial degeneration, but the young are condemned to certain death from a characteristic disorder of small vessels, if other hazards of diabetes are avoided (Mirsky 1946) Now that these hazards are becoming relatively unimportant, the patient with advancing vascular disease is becoming rapidly more common That vascular disease, both atherosclerosis and capillary damage, is more common in diabetics than in non-diabetics is the finding of all substantial inquiries both in living and in dead subjects (Liebow et al 1955, Bell 1950) Capillary lesions are seen with increasing frequency the longer diabetes persists, but atherosclerosis, though abnormally common, seems not to be related to the duration of diabetes (Mirsky 1946)

Atherosclerosis and diabetic "angiopathy," as Lundbæk (1954) has named the capillary disease of diabetes, may be considered separately, it is not to be assumed too readily that they are unrelated, for we have to remember that the angiopathy can be detected in the retina at a very early stage and in the kidney by inference from examination of the urine, whereas atherosclerosis can only be diagnosed in life by rather gross clinical signs At present there is no conclusive evidence that the arterial lesions differ from those of patients without diabetes On the other hand, the picture of diabetic angiopathy is gaining definition The histological changes in the retina described by Ballantyne and Loewenstein (1943) remain specific for diabetes Ashton (1951) found similar, though not identical, changes in non diabetic eyes, but the over all picture is entirely individual The same is true of the renal disorder In view of the tendency of pathologists to disagree, the relation of the nodular lesions in the glomeruli to diabetes has been accepted to a remarkable extent (Bell 1950) Apart from other resemblances, the staining reactions of the hyaline material with the periodic acid stain suggest that the lesions in the kidney and the retina are manifestations of a single disorder, and studies of necropsy material (McManus 1950) confirm that they coexist in all fatal cases It is this angiopathy, believed to be a specific complication of diabetes, which is under consideration for possible relief by adrenalectomy Perhaps the lesions occur elsewhere than in the retina and kidney, but it is in these sites that arise the symptoms which justify a desperate remedy To make a firm criterion for such an interference it is necessary first to consider the clinical course of retinopathy and nephropathy in the absence of specific treatment

Course of Retinopathy

The ophthalmoscopic picture of diabetic retinopathy, first described with any accuracy by Hirschberg (1890), was classified by Ballantyne (1946) on the basis of many histological examinations The evolution from the earliest changes (micro aneurysms) to the final destruction of the

FFECTS OF FEEDING DIFFERENT FATS ON SERUM-CHOLESTEROL LEVEL

A SURVEY of the multiracial community residing in he Cape Peninsula revealed that the widely differing nter racial incidence of coronary heart disease was associated with a parallel difference in the mean serum-cholesterol levels (Bronte Stewart et al. 1955a). Within each racial group the serum cholesterol level was highest in those on the highest economic plane and bore a parallel relationship to the intake of foods rich in fat of animal origin. There was no correlation with the intake of vegetable fat. Diets which through economic privilege have increasing quantities of foods containing animal fat also have increasing quantities of animal proteins, with resulting changes in the intake of vitamins, and decreasing quantities of starch and cellulose. It became necessary, therefore, to study the effect of various foodstuffs on the serum cholesterol level under controlled conditions.

Material

This study was conducted on two groups of people: volunteers with initial low serum-cholesterol levels and ccustomed to a low-fat diet (about 17% of calories rom fat), and 2 patients with initial high serum-cholesterol levels and accustomed to a diet rich in animal fat. The 2 patients, who agreed to cooperate in the investigation, were European males, aged 38 and 42, with angina pectoris and electrocardiographic evidence of coronary heart disease. The 6 volunteers were 5 Bantu males and 1 Cape Coloured male from the poorer economic strata. With 1 exception, no abnormal physical signs were observed in the volunteers during the study. 4 had been admitted with vitamin deficiency syndromes and had received vitamin therapy before the start of this study, and these vitamin supplements were continued throughout. The 1 exception was studied during physiotherapeutic rehabilitation after hemi plegia, probably syphilitic. Physical activity was minimal throughout the study.

Diets Used

Throughout the study the 2 Europeans with coronary heart disease were kept on a constant diet containing a moderate amount of fat (50 g. daily) almost exclusively of animal origin in the form of butter, milk, and meat. The basic diet of the 6 non-European volunteers consisted of maize-meal products and white bread supplemented by sugar and casein to maintain by suitable adjustment an isocaloric and isonitrogenous state. This diet is free from cholesterol, and the small amount of fat present is that contained in the maize and bread, estimated to be not more than 3% of the total calories (Fox and Golberg 1944). The first 2 non-Europeans were studied without casein supplements and were maintained on a protein-poor diet (28 g. daily) throughout by the use of finely sifted maize meal (baker's cones). In another volunteer the intake of protein was deliberately altered by changing from baker's cones to standard maize meal (an increase of about 7 g. of protein daily) and later supplementation of this daily intake of protein with 100 g. of casein.

To these diets various fats and oils were added one at a time, usually in amounts of 100 g., to increase the proportion of calories derived from fat from the basic 3% to 36% and 45% and, on occasion, to 60–70% (200 g.). With this sudden increase in intake of fat transient diarrhœa developed on two occasions but ceased spontaneously without reduction of the intake of fat. The oils were administered either as a draught or incorporated in the food, according to individual preference. When the oils were given in cooked food, this was fried at moderate or low temperatures. In view of Page's (1954) warning that there may be an individual variation in the response to fat feeding, our policy was to try several different fats on the same person.

Methods

Blood was drawn every other day with the subject fasting, and the cholesterol was estimated in duplicate, firstly in the fresh sera, and secondly on filter-paper containing the electrophoretically separated lipoproteins by the method of Abell et al. (1952) modified by Anderson and Keys (1955) as in the previous survey (Bronte-Stewart et al. 1955a). Cholesterol in stools was estimated by the same method.

With this method, storage of the frozen sera did not affect the cholesterol values. Use was made of this to cross check the trends that evolved by re estimating a specimen of serum from the previous week. By these methods the same fat given three months later to the same volunteer produced almost identical serum-cholesterol levels (figs. 2 and 6).

Isolation of Fatty acid Fractions

Two fatty acid fractions were separated from sunflower seed oil by fractional crystallisation from acetone

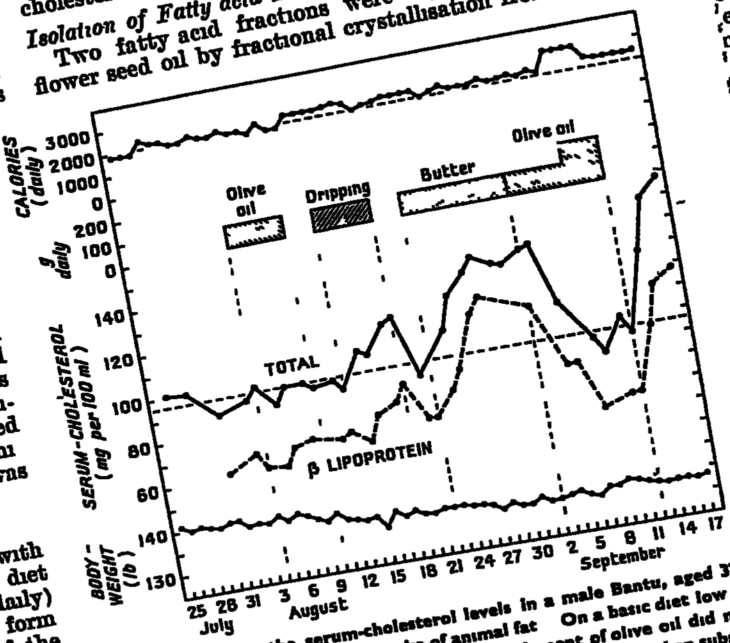

Fig. 1—Changes in the serum-cholesterol levels in a male Bantu, aged 37, coincided with changes in the intake of animal fat. On a basic diet low in protein and fat and free from cholesterol a supplement of olive oil did not raise the serum cholesterol level or maintain the raised level when substituted for butter. Even when the olive-oil supplement was doubled so that it provided over 60% of the total calories, the serum-cholesterol level did not rise again until a "full diet" consisting of beef and vegetables (fat-content about 140 g.) was given. The mean serum cholesterol level before fat feeding was 95.6 ± 5.5 mg. per 100 ml.

The unchanged state of cases 3–6 may not be an entirely negative result Certainly in cases 3 and 4 a further deterioration as a result of renal disease was to be expected, even within the limited follow-up

Control of Diabetes

It is difficult to calculate, except in general terms, any change in the ease with which the diabetes was controlled These patients after operation were attending frequently and were under close observation, hence adjustments of insulin dosage or of diet were readily made There did not appear to be any significant difference in average blood-sugar level, total glycosuria daily, or incidence of hypoglycæmia after the operation, except in case 5, who achieved an average blood-sugar level of 150 mg per 100 ml and a daily output of less than 5 g of glucose on the same dosage of insulin—16 units daily Possibly the improvement was entirely due to improved care with diet The patient has had one attack of insulin coma, due to delay of a meal, since operation This is the only major episode of hypoglycæmia in the whole series

Insulin Dosage

In Wortham and Headstream's (1953, 1954) series the insulin dosage after adrenalectomy was two thirds of that before operation After hypophysectomy in Olivecrona's series (Luft et al 1955) the average was from a quarter to a third of the preoperative dosage In the present series there was no significant reduction in insulin dosage This may be due to the use of a comparatively large maintenance dosage of cortisone (50 mg) The possibility of supplementing a lower dosage with deoxycortone acetate was considered but rejected Luft et al (1955) no longer use deoxycortone acetate, because of its unfavourable effect on damaged blood-vessels

Retinopathy

In case 2 vitreous hæmorrhages, which were taking place at least once a fortnight, have ceased, there being no recurrence since the operation The appearance of retinitis proliferans persists, but the visual acuity in each eye is 6/6 In cases 3 and 4 there has been no detectable change in the retinopathy, but, since massive vitreous hæmorrhage had already obscured the fundus, it is impossible to be certain

In case 5 fresh vitreous hæmorrhage recurred two months after the operation and was followed by glaucoma with total loss of vision in the left eye Fortunately the right eye, amblyopic because of a squint, was only slightly affected by retinopathy, and the visual acuity is slowly improving Case 6 has been followed for only four months, and the absence of change is not significant

Albuminuria

Apart from case 1, already in advanced renal failure, cases 3 and 4 have shown no sustained improvement in daily albuminuria Six months after the operation both showed a significant decrease—from 5 to 2 g and from 2 to 0 g —but three months later there had been a return to the preoperative levels

Blood pressure

In cases 3 and 4 there was no reason to doubt that the hypertension was renal in origin, the reduction in blood-pressure cannot be considered significant after so short a follow up In case 5 a rising blood-pressure had been noted for seven years, and a diagnosis of essential hypertension was accepted

Discussion

If these results are considered in conjunction with those of Wortham and Headstream (1953, 1954), certain conclusions may be advanced in spite of the small number of patients, they are those which common sense suggests

(1) The operative mortality of total adrenalectomy in patients with diabetic vascular disease not having renal failure is negligible

(2) Maintenance with cortisone after total adrenalectomy is simple

(3) The general health is not made worse by total adrenalectomy

(4) Control of the diabetes is unaffected by total adrenalectomy

(5) Retinopathy and renal damage may be halted at an early stage, this cannot be established until after a longer follow up Advanced retinopathy is not altered, and renal failure, if established, is accelerated

Selection of Material

It is now generally agreed that the most urgent clinical problem in diabetes is the vascular disease which seems to develop inevitably if the patient lives sufficiently long Those whose diabetes starts after the age of 50 may live to old age without apparent acceleration of arterial degeneration, but the young are condemned to certain death from a characteristic disorder of small vessels, if other hazards of diabetes are avoided (Mirsky 1946) Now that these hazards are becoming relatively unimportant, the patient with advancing vascular disease is becoming rapidly more common That vascular disease, both atherosclerosis and capillary damage, is more common in diabetics than in non-diabetics is the finding of all substantial inquiries both in living and in dead subjects (Liebow et al 1955, Bell 1950) Capillary lesions are seen with increasing frequency the longer diabetes persists, but atherosclerosis, though abnormally common, seems not to be related to the duration of diabetes (Mirsky 1946)

Atherosclerosis and diabetic "angiopathy," as Lundbæk (1954) has named the capillary disease of diabetes, may be considered separately, it is not to be assumed too readily that they are unrelated, for we have to remember that the angiopathy can be detected in the retina at a very early stage and in the kidney by inference from examination of the urine, whereas atherosclerosis can only be diagnosed in life by rather gross clinical signs At present there is no conclusive evidence that the arterial lesions differ from those of patients without diabetes On the other hand, the picture of diabetic angiopathy is gaining definition The histological changes in the retina described by Ballantyne and Loewenstein (1943) remain specific for diabetes Ashton (1951) found similar, though not identical, changes in non diabetic eyes, but the over-all picture is entirely individual The same is true of the renal disorder In view of the tendency of pathologists to disagree, the relation of the nodular lesions in the glomeruli to diabetes has been accepted to a remarkable extent (Bell 1950) Apart from other resemblances, the staining reactions of the hyaline material with the periodic acid stain suggest that the lesions in the kidney and the retina are manifestations of a single disorder, and studies of necropsy material (McManus 1950) confirm that they coexist in *all fatal* cases It is this angiopathy, believed to be a specific complication of diabetes, which is under consideration for possible relief by adrenalectomy *Perhaps the lesions* occur elsewhere than in the retina and kidney, but it is in these sites that arise the symptoms which justify a desperate remedy To make a firm criterion for such an interference it is necessary first to consider the clinical course of retinopathy and nephropathy in the absence of specific treatment

Course of Retinopathy

The ophthalmoscopic picture of diabetic retinopathy, first described with any accuracy by Hirschberg (1890), was classified by Ballantyne (1946) on the basis of many *histological examinations* The evolution from the earliest changes (micro aneurysms) to the final destruction of the

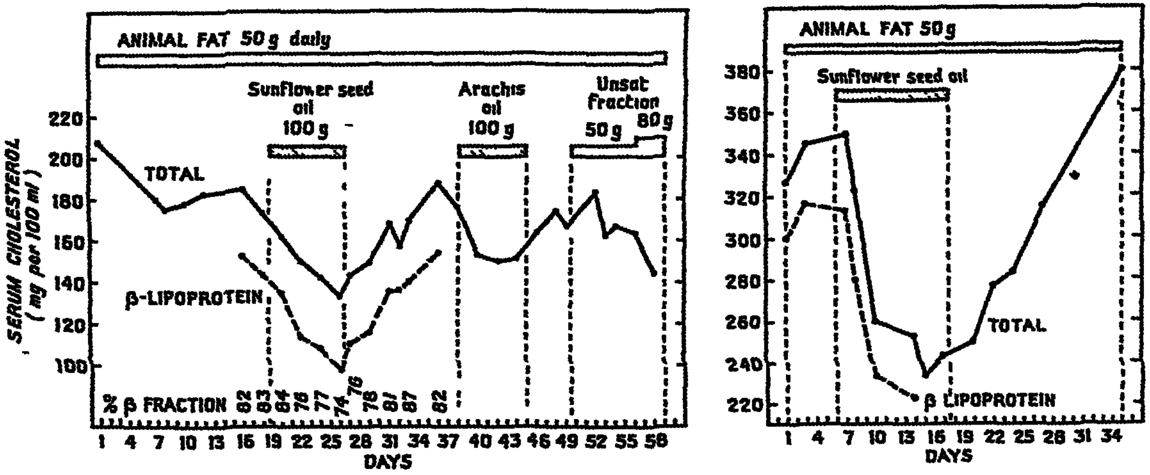

Fig 4—The effect is shown, in 2 Europeans, aged 38 and 42, with coronary heart-disease of increasing the intake of fat from 50 to 150 g daily by the addition of 100 g of sunflower-seed oil In the lower register withdrawal of sunflower-seed oil was followed by a large rise in serum-cholesterol level In the upper register both arachis oil and the unsaturated fraction prepared from sunflower-seed oil produced a similar response to that of sunflower-seed oil

oil (iodine value 230), used industrially in the hardening of hardboard, appeared to be more effective than sunflower-seed oil in countering the effect of ten eggs daily (fig 6)

USE OF SATURATED AND UNSATURATED FATTY-ACID FRACTIONS

In Supplementation of Hydrogenated Fat

These attempts might have been more convincing had we known earlier that the unsaturated fatty-acid fraction used in this experiment contained only 60–65% of linoleate When this became known, the 100 g of hydrogenated fat had to be supplemented with as much as 84 g of this unsaturated fraction to achieve the desired 27% of linoleate, the estimated proportion in the non-hydrogenated oil At this dosage there was insufficient for more than three days' feeding, but despite this great increase in the intake of fat, the serum cholesterol level fell On withdrawal of this unsaturated fraction the serum-cholesterol level rose again

In Substitution for Sunflower-seed Oil

Apart from the experiment outlined above, the unsaturated fatty-acid fraction was fed to 1 European volunteer with coronary heart disease in an attempt to reproduce the effects of the 100 g of sunflower seed oil and ground-nut oil supplements (fig 4) In this volunteer the serum-cholesterol level promptly fell when these oil supplements were given, despite the continued consumption of the basic diet containing 50 g of animal fat When 50 g of the unsaturated fatty acid fraction (estimated linoleate content 37 g) was added to this basic diet, no immediate effect was noted until a freshly prepared fraction was used This delay, which may be attributable to isomerisation, is discussed below

Rôle of Intake of Cholesterol with Highly Unsaturated and Saturated Fatty Acids

The effect of 100 g of fat consumed as ten eggs far exceeds that of equivalent amounts of hydrogenated ground nut fat (fig 2) Eggs contain protein cholesterol, and fat In 1 volunteer (fig 7) keeping the diet isonitrogenous by feeding casein after the withdrawal of the ten eggs did not maintain the rise in the serum cholesterol level The addition of 3 g of cholesterol (equivalent to that in ten eggs) raised the serum-cholesterol level but not so high as it had been When the quantitatively equivalent fat-content of ten eggs was supplied in a qualitatively dissimilar form (as sunflower seed oil) the serum cholesterol level fell despite the continued consumption of cholesterol and casein On withdrawal of the sunflower seed oil the serum-cholesterol level rose again At this point 60 g of the ethyl-linoleate fraction (the amount estimated to be present in 100 g of sunflower-seed oil) given daily for six days reproduced these effects When 15 g of the saturated fatty-acid fraction from sunflower-seed oil was fed, the serum-cholesterol level rose sharply At this stage the total intake of fat represented only 8% of the total calories

The use of 30 g of the saturated fraction in another subject was not associated with the same sharp rise Over 18 days there was a gradual rise in the serum-cholesterol level from 100 to 145 mg per 100 ml From the eighth day of this period a more freshly prepared saturated fraction was given together with 0 6 g of cholesterol, and the effect appeared to be more pronounced The subsequent administration of massive doses (1000 mg daily) of commercially prepared vitamin E ('Natopherol,' Abbott) in addition on the twenty-third day was not associated with an immediate fall in the serum-cholesterol level such as was seen with the pilchard oil, but six days later a slight fall occurred (Not only was this dose far in excess of that present in natural oils but also the vehicle is an oil which may have a high unsaturated fatty-acid content)

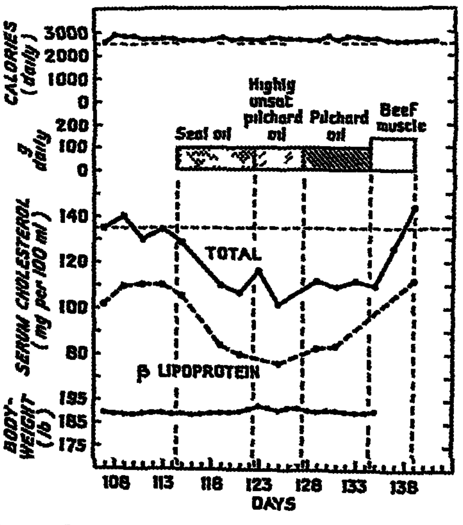

Fig 5—In same Bantu as in fig 3 during feeding of supplement of 100 g of various marine oils the serum-cholesterol levels remained considerably lower than during the low-fat cholesterol free control period Substitution of beef muscle for marine oils was followed by a prompt rise in serum-cholesterol level

the diagnosis, but glomerulosclerosis may accompany this disorder (Rifkin et al 1952) The term " nephropathy " is preferred by Wilson et al (1951) because of the difficulty in making this distinction The finding of doubly refractile lipoid casts in the urine is the most characteristic sign of glomerulosclerosis, but serial examinations are required, and their presence is not pathognomonic Recent experience indicates that the overwhelming majority of diabetic patients under the age of 50 with chronic renal disease have glomerulosclerosis In all my 17 cases the diagnosis was confirmed at necropsy, after having been made clinically from the finding of persistent symptomless albuminuria This is the first clinical manifestation and continues for a variable period before there are added hypertension, impaired renal function, and perhaps œdema Death takes place from renal failure or less often from congestive cardiac failure in fact, these conditions usually coincide in the terminal phase

Glomerulosclerosis is a progressive condition with a grave prognosis, death taking place in from two to five years Mann et al (1949) give an average survival of 6 4 years after the onset of nephrosis in 16 fatal cases of renal disease complicating diabetes, but in 8 of these there was no necropsy Rifkin et al (1952) did not feel justified in stating the duration of life, because they could not date the onset exactly In my series the onset of albuminuria could be dated to within six months because the urine was examined for albumin at each routine attendance If the first finding of albuminuria, rather than the onset of nephrosis, is taken as the point of onset of glomerulosclerosis, the average survival in the 17 cases was 5 2 years

Indications for Adrenalectomy

If we accept the view that the vascular disease of diabetes is progressive and will ultimately lead to disablement and death, and that adrenalectomy is worth considering as a possible means of arresting this process, we are confronted with a most awkward problem when we come to select the suitable case The earliest detectable lesions (in the retina) may remain stationary for years, and only an extreme enthusiast would consider so drastic an operation as adrenalectomy at this stage On the other hand, the later stage of retinitis proliferans or of renal insufficiency is almost certainly beyond the possibility of reversal by any form of treatment We have to hit on a period when we can say with reasonable certainty that the vascular disease has reached a point from which it will, if untreated, inevitably progress to blindness or renal failure within five years, yet the damage must *not* have reached an irreversible stage Such a period may be brief and implies frequent examination of those in whom vascular disease has been detected

The positive indications seem to be (1) retinitis proliferans as soon as diagnosed, and (2) glomerulosclerosis of a degree indicated by the following positive features albuminuria constantly present for six months, a diastolic blood-pressure above 90 mm Hg after a week of rest in bed, and diabetic retinopathy Doubly refractile lipoid casts in the urine strongly support the diagnosis but are not pathognomonic The same applies to œdema of insidious onset Negative features are the absence of blood casts from the urine and the absence of urinary infection, but it has to be remembered that such do not absolutely exclude glomerulosclerosis Either of these indications found alone would justify adrenalectomy

Contra-indications against Adrenalectomy

(1) *Advanced renal disease* —If the blood-urea level, in the absence of fluid and electrolyte disturbance from vomiting or from uncontrolled diabetes, is persistently above 70 mg per 100 ml, renal failure is likely to be aggravated by adrenalectomy

(2) *Retinopathy at Ballantyne's stage 4* —There are unusual cases in which episodes of repeated vitreous hæmorrhage are succeeded by years of adequate vision, and others, more rare, in which renal damage seems to remain stationary for several years, but the overwhelming majority of diabetics with capillary lesions tend to deteriorate progressively If good functional results are to be achieved, the risk of treating an occasional patient unnecessarily may have to be taken and the decision to intervene reserved for relatively early lesions It would be easier to convince our patients and ourselves that this decision is right, if evidence of arrest of vascular damage over a substantial time by adrenalectomy could be brought forward At present the apparent successes are not outside the range of spontaneous remission It can at least be said that total adrenalectomy is safe, and that the postoperative maintenance of the patient need not be a burden A life as tolerable as that before operation is possible, and control of the diabetes will be no less easy

Summary

Total adrenalectomy was undertaken for vascular disease in 6 diabetic patients Retinopathy was the indication in all the cases The follow up period was from five to sixteen months

1 patient, already uræmic, died of renal failure two weeks after the operation In the remainder the operation was uneventful Retinopathy was improved in 1, unchanged in 3, and worse in 1 Albuminuria was unchanged in the 2 patients in whom it was found before the operation

Control of the diabetes was unchanged

The general health was better in 1 patient and unchanged in 4

The main indications, if any, for adrenalectomy are retinitis proliferans as soon as it is diagnosed and persistent albuminuria in the absence of urinary infection

I should like to thank Dr F E Higgins, who was largely responsible for the care of these patients at the time of operation, and Mr J A C Edwards for carrying out the operations faultlessly

ive oil and ground-nut oil did not raise the serum- holesterol levels Ground-nut oil fed as the hardened r hydrogenated form behaved differently from the atural oil This was regarded as a significant finding because one of the changes consequent on hydrogenation of oils is the destruction of the highly unsaturated fatty acids in their conversion to more saturated fatty acids which raises the melting-point (Deuel et al 1951) The highly unsaturated fatty acid affected predominantly in ground-nut oil is linoleic acid, which has been regarded by Burr (1942) as an essential fatty acid having metabolic functions other than the supply of calories Oleic acid and the saturated fatty acids did not appear to have these functions

Other essential fatty acids listed by Burr (1942) are linolenic, hexahydroxystearic, arachidonic, and docosahexaenoic acids , the last named two being present in high concentration in marine oils (Bailey 1945, W S Rapson personal communication) In a given dosage the biological activity of these latter essential fatty acids exceeds that of linoleic acid (Deuel 1955) Marine oils approach vegetable oils in their consistency at room-temperature and fatty-acid composition They do not ontain sitosterol and have a very low content of vita in E, but the cholesterol content does not greatly differ rom that of beef (Lange 1950)

Rôle of Dietary Intake of Cholesterol

We concur with the views of Messinger et al (1950), Keys (1952), and Mayer et al (1954) that the changes in the serum cholesterol level are due to some factor additional to the cholesterol content of the dietary fat Messinger et al (1950) noted greater effects when the cholesterol supplement was given with cream , we believe that this supports our view that an additional factor is the type of fatty acid in the fat concerned Our view is based on the fact that a possible common difference between animal fats and hydrogenated vegetable fat, on the one hand, and natural vegetable oils and marine oils, on the other, is not the cholesterol, sitosterol, vitamin, or protein content but is in some way connected with the proportion of highly unsaturated and saturated fatty acids in the fat concerned

In feeding experiments on rats Swell and others (1955) found greater rises of the serum cholesterol level when cholesterol was given with saturated fatty acids compared with unsaturated fatty acids They emphasise the importance of the nature of accompanying fatty-acid intake in the esterification and absorption of cholesterol

Our results with sunflower seed oil (iodine value 130–138) containing about 60% of linoleic acid (Bailey 1945) are not unlike those described by Kinsell and Michaels (1955) In their diabetic patient the extent of the fall in the serum-cholesterol level could be related to the unsaturated fatty-acid content of the vegetable oil used The most active was soy oil (iodine value 134) containing about 55% of linoleic acid and 6% of linolenic acid (Bailey 1945) Ahrens et al (1955) too found that corn oil, an oil rich in linoleic acid, was effective in this regard

Effect of Fatty acid Fractions

It appears to us that the data obtained in these experiments may reasonably be explained by the concept that the fatty-acid composition of the fat consumed determines the effect on the serum cholesterol levels Whether the effects produced depend on the fatty acids or on some accompanying factor is not yet explained Experiments with the pure fatty-acid fractions are being made, and a highly unsaturated fraction, when used soon after preparation, produced effects similar to those of sunflower seed oil , this fraction was free from sitosterol but contained a little vitamin E Although vitamin E in 1 volunteer appeared to produce a moderate fall of the serum cholesterol level, the dosage used was far in excess of that present in vegetable oils , moreover this preparation (derived from vegetable oils) may be rich in unsaturated fatty acids Vitamin E is not present in high concentration in marine oils, which nevertheless consistently depressed the serum cholesterol level

The unsaturated fraction that did not affect the serum-cholesterol levels had been redistilled in vacuo (±1 mm Hg) three times and, on subsequent testing, was found to contain about 20% of conjugated linoleic acids formed by isomerisation either during distillation or in the initial saponification of the sunflower seed oil Burr (1942) has shown that the isomer of linoleic acid, 9–11 linoleic acid, has no biological activity

The estimated vitamin-E content of this fraction was about four times that of the fresh unsaturated fatty-acid fraction that was effective later

Possible Applications to Coronary Heart-disease

The magnitude of the problem of coronary heart-disease has prompted us to publish these preliminary results Owing to difficulties in obtaining a sufficiency of the pure fatty acid fractions, or the pure fatty acids contained therein, our results are incomplete, but they show a very consistent trend

This consistency has applied particularly to the depressant effect on the serum cholesterol level of oils with high unsaturated fatty acid content On feeding supplements of animal fat the serum cholesterol levels were consistently raised, but not so high in the post-hemiplegic patient as in the others This raises the possibility that individuals may vary in their response to the dietary intake of fat

The serum cholesterol levels usually changed within forty eight hours of the dietary change, which is the time taken for the specific activity to reach its peak in isotope studies (Hellman et al 1955) Although the length of the feeding periods varied, it is quite possible that different effects might have been observed if these experiments had been continued longer

The application of these findings to certain problems in the ætiology of coronary heart disease depends on the acceptance of the views that coronary heart disease is in part a disorder of cholesterol and related lipoid metabolism, that there is a relationship between natural atherosclerosis in man and experimental atherosclerosis in laboratory animals, and that epidemiologically there is a relationship to the dietary intake of fat

Metabolism

The interrelationship of the essential fatty acids and cholesterol metabolism is becoming well documented (Kelsey and Longenecker 1941, Alfin Slater et al 1954, Deuel 1955, Peifer and Holman 1955, Shapiro and Freedman 1955, Swell et al 1955) Apart from the different sex requirements in the younger age groups (Cheng et al 1952) there are reported differences in capillary permeability and fragility which can be reversed by changing the intake of fat from animal to vegetable in man and by feeding ethyl linoleate in the rat (Kramar and Levine 1953)

Kritchevsky et al (1954) noted lower serum cholesterol levels and less atherosclerosis in rabbits fed cholesterol with 9% corn oil (iodine value 130) compared with rabbits on comparable cholesterol diets with 9% hydrogenated fat (iodine value 92) The possibility exists that atherosclerosis is intensified by a dietary deficiency of essential fatty acids In support of this theory is the finding of Alfin Slater et al (1954) of an increase in cholesterol ester in the livers of rats on low-fat diets On the other hand, Hartroft (1955) has reported increased deposition of fat in the liver when the intake of saturated fatty acids is high It is therefore of interest that, in man, Hammond and Lundberg (1955) have demonstrated differences between the fatty-acid content of the blood of atherosclerotic patients and blood donors, the former having a lower proportion of linoleate and arachidonate

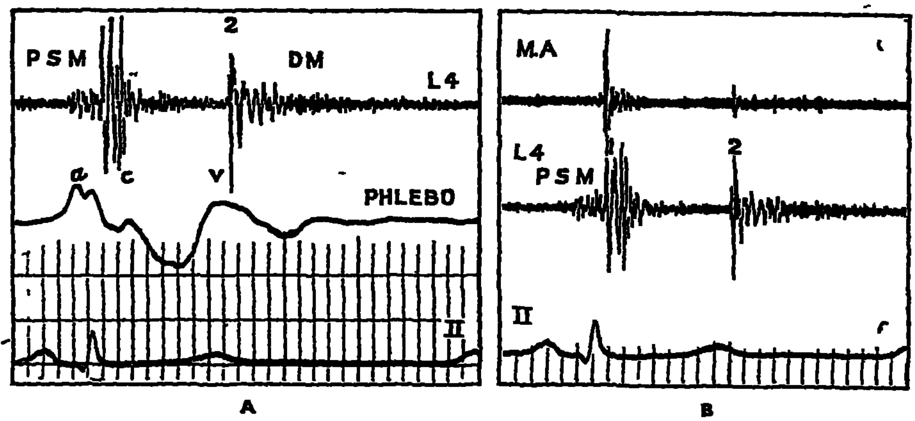

Fig 4—A, phlebogram showing dominant *a* wave in jugular venous pulse, B, phonocardiograms from mitral area and left 4th space, showing absence of mitral murmurs after mitral valvotomy

Postoperative Course—This was uneventful apart from a short attack of precordial pain, probably due to pericarditis, on the tenth day

Follow-up—Six months after valvotomy the patient was slightly improved but still had severe effort intolerance, being able to walk only 200 yards She was now, very interestingly, limited mainly by angina, the dyspnœa (due to pulmonary venous congestion) having been diminished by the mitral valvotomy Auscultation showed that the apical presystolic murmur and opening snap were now absent and the first sound was softer (fig 4) A fairly loud opening snap, presumably from the tricuspid valve, was recorded graphically from the left 4th space during inspiration (fig 5) but was not detected clinically During the next six months the angina became more severe, bringing the patient to a halt after walking only 50 yards on the flat, and sometimes being present at rest Electrocardiography after effort showed ischæmic changes (ST depression)

Tricuspid valvotomy was done a year after the mitral valvotomy The cavity of the right atrium was very large The tricuspid orifice was small, being just under 1 cm long, palpation gave the impression of a round opening in a fairly thin resilient membrane moving very little with systole A small regurgitant jet was felt near the posterior wall A finger was thrust through the opening without any difficulty, and the valve was felt to split, apparently posterolaterally Some ballooning of the anterior part of the valve could be felt which was comparable to that in the aortic cusp of a stenosed mitral valve, though not nearly so pronounced After the split the orifice measured 3 × 1 5 cm and was 7 cm in circumference, and a definite increase in the regurgitant stream was felt A systolic thrill was now palpable over the right atrium The atrium was less distended, its surface appearing wrinkled instead of smooth, and atrial contraction was stronger and more effective On direct auscultation before valvotomy a fairly long and rather low pitched diastolic murmur was heard over the right ventricle, but an opening snap was not detected

Postoperative Course—After the operation the patient got up on the third day and was discharged on the eighteenth day, there were no complications After tricuspid valvotomy there was a dramatic symptomatic improvement the anginal pain completely disappeared even on exertion, whereas before operation it occurred daily while the patient was at rest in bed in hospital The patient was, however, still limited by breathlessness and could only walk slowly about half a mile on the flat, stairs were managed if taken slowly On examination there was still a prominent though diminished 4 cm *a* wave in the neck The tricuspid diastolic murmurs were still present, and the tricuspid opening snap was still recorded on the phonocardiogram In addition a soft tricuspid systolic murmur had appeared since the valvotomy The aortic diastolic murmur was unchanged

Cardiac catheterisation three months after tricuspid valvotomy showed that the tricuspid gradient had been diminished in atrial systole from 10 to 6 mm Hg and in diastole from 4 to 2 mm Hg Since the cardiac output had risen by 25% between the two observations, the reduction of the gradient by about 50% is undoubtedly significant The P C V pressure of 9 mm Hg was slightly less than the figure of 11 mm Hg obtained before mitral valvotomy, as was the degree of obstruction at the mitral valve measured by the Ry/V of 1 38 compared with 0 9 Some degree of mitral stenosis is present, accounting for the breathlessness still experienced

Discussion

Cossio and Perianes (1949) described the production of incompetence of the normal tricuspid valve by passing an instrument through the jugular vein for the relief of chronic pulmonary congestion Surgical relief of rheumatic tricuspid stenosis was first reported by Brofman (1953), and since then, including the present case, 19 cases have been published, with no operative deaths (Bailey 1955, Chesterman and Whitaker 1954, Doghotti 1954, Krook et al 1955, O'Neill et al 1954, Rubio and Lason 1954, Swan et al 1955, Trace et al 1954)

The sex ratio was 7 women to 2 men in the 9 cases in which the sex was stated, with an age range of 21-43 (mean 29) The mean age at mitral valvotomy is 36 8 years (Wood 1954) This accords with the finding of Thompson and Levine (1937) that the average age at onset of symptoms in rheumatic heart disease is earlier when tricuspid stenosis is present Of the 19 cases, the diameter of the tricuspid valve orifice was 5-13 mm in 5, and was described as tight in 3 others and moderate in 1, no details being given of the remainder The shape was triangular, circular, or slit-like In some cases, as in the present one and that of Chesterman and Whitaker (1954), the valve orifice appeared as a circular opening in a smooth diaphragm, and it was impossible to feel the individual commissures In others it is stated or implied that one or more of the commissures could be detected Calcification in the valve has not been reported

A direct approach to the valve was used by all except Rubio (Rubio and Lason 1954), who uses a cutting wire in the end of a ureteric catheter Most workers have found that instrumental division of the valve was often required, although none states that valvotomy was especially difficult

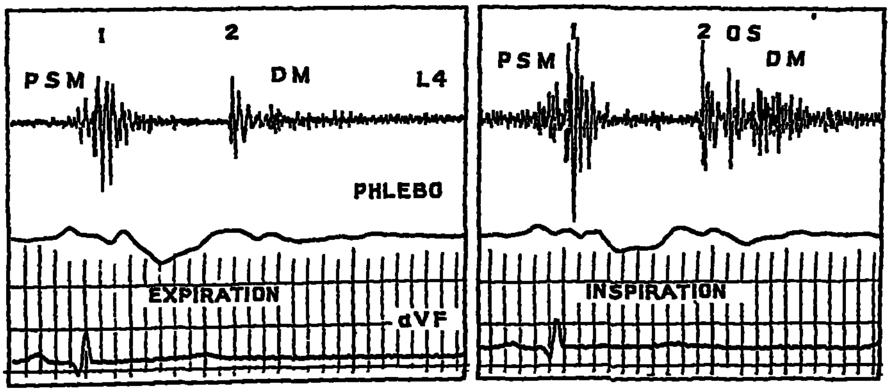

Fig 5—Phonocardiograms from left 4th space, showing increase in intensity of diastolic murmurs on inspiration, and emergence of opening snap (O.S)

TREATMENT OF TETANUS

SEVERE BONE-MARROW DEPRESSION AFTER PROLONGED NITROUS-OXIDE ANÆSTHESIA

H. C. A. Lassen

BLEGDAM HOSPITAL, COPENHAGEN

Since the 1952 epidemic of poliomyelitis in Copenhagen the therapeutic measures introduced in the management of the life-threatening forms of infantile paralysis have been adapted to several other diseases presenting similar problems—e.g., tetanus.

Bjorneboe et al. (1953) were the first to describe a severe case of tetanus cured by treatment along these lines, and Lassen et al. (1954) gave a detailed account of 4 such cases. Since then cases have been published by Shackleton (1954), Forrester (1954), Haglund (1955), and Mollaret et al. (1955).

When the conventional treatment of tetanus with barbiturates, chloral hydrate, or bromethol does not totally suppress the spasms, or if adequate ventilation is threatened by accumulation of secretion in the upper respiratory passages, eventually followed by atelectasis, a high tracheotomy under general anæsthesia preceded by oral intubation should be done and an inflatable rubber cuff-tube inserted into the trachea.

This procedure secures against suffocation due to laryngeal spasms or tetanic standstill of the respiratory muscles. At the same time aspiration through the tube makes it possible to keep the airway free from secretions.

Convulsions and rigidity can be kept in check with *d*-tubocurarine chloride given either continuously through an intravenous drip or by repeated intravenous injections. When, however, convulsions are severe, the requisite dosage of tubocurarine invariably produces inadequate ventilation because of failure of the respiratory muscles, and artificial respiration (some kind of positive pressure ventilation) becomes necessary.

Tetanus does not affect the patient's mental state, nor does curare. In severe curarised cases therefore the patient is totally paralysed but fully conscious, aware of everything that is going on around him, and no doubt subjected to great emotional strain. He appears stuporous, cannot talk, and, since even the slightest movement of the muscles is suppressed, cannot communicate with anybody by either gestures or facial expression. The treatment of tetanus often has to be continued for many weeks, and we tried to find ways to avoid the long-continued psychological strain. For this purpose nitrous-oxide anæsthesia seemed ideal. It produces a mild narcosis, which reduces the need for curare and sedatives. No harmful side-effects are known, and the anæsthetic is easy to administer continuously to patients on spontaneous respiration as well as to patients on artificial respiration. In most cases we used a mixture of 50% oxygen and 50% nitrous oxide.

Hæmatological Complications

The first 2 patients treated on these lines were cured and left the hospital without sequels. Severe tetanus is thus a self-limited disease and all its symptoms and all complications are reversible.

At that time we felt rather optimistic, but further experience proved us to be too optimistic. The 3rd patient treated in this way was a boy aged 15 with fulminant tetanus. After seventeen to eighteen days' treatment the tetanus subsided, continuous anæsthesia with nitrous oxide and oxygen was discontinued, medication with curare was stopped, and he only needed moderate doses of chloral hydrate to keep him relaxed. But at this time signs of aplastic anæmia developed.

Fig. 1 shows that, despite repeated blood-transfusions, pronounced granulocytopenia and thrombocytopenia with

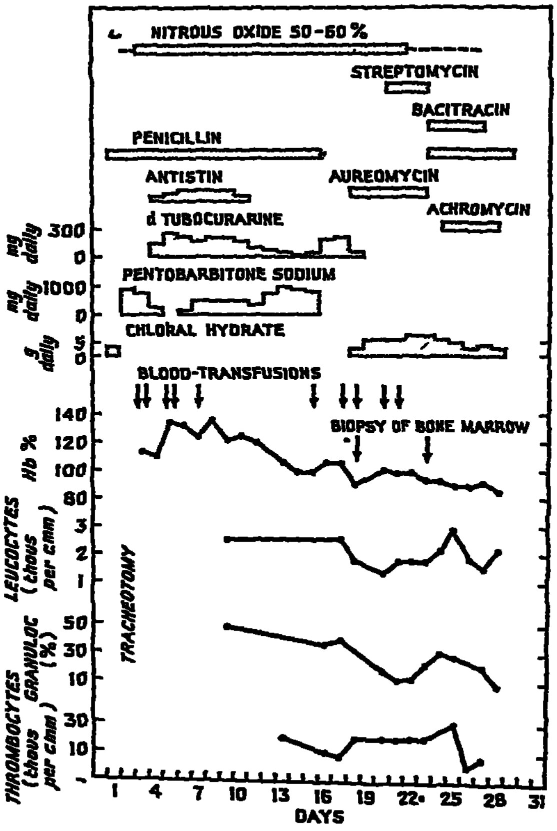

Fig. 1—Changes in peripheral blood in relation to medication in a boy, aged 15, with severe tetanus.

Total responding		23	20	

Hydrocortisone powder was used rather than the suspension, because in this way the substance reaching the mucosal surface is undiluted, non-irritant, and retained in the nose more easily The powder, which was ground very finely * was supplied in 100 mg capsules containing 15 mg of hydrocortisone acetate and 85 mg of lactose The capsules were pierced at the upper end and placed in a nasal insufflator from which a fine spray was produced This spray was applied to both nostrils three times a day, the whole 15 mg being used in twenty-four hours

In many cases the initial blockage of the nose by the hay fever made it necessary to create an airway to allow the powder to reach the nasal mucosa These patients were therefore asked to instil into both nostrils one or two drops of 0 02% naphazoline ('Privine'), to unblock the nose When the naphazoline had freed the airway, the hydrocortisone powder was inhaled, and this pre treatment with naphazoline was discontinued when the airway remained clear (in most cases after two days).

The hydrocortisone inhalations were kept up for five days and then omitted to see if relapse occurred, but further hydrocortisone was given if and when symptoms recurred Those patients in whom a partial control of symptoms had previously been obtained by anti-histamine substances continued with the same drug and dosage throughout in addition to the hydrocortisone

Results

No side effects of any kind were observed during the treatment The powder was applied without difficulty once the patients had mastered the fact that it was useless to apply it to a blocked or watering nose With perseverance every patient except 1 (case 20) was able to free the nose temporarily with the naphazoline before applying the powder In no case was local irritation of the nose produced by the powder

The initial response to hydrocortisone was excellent (table I) All the patients but 1 obtained relief from nasal symptoms within ten days, and most of them responded dramatically within forty eight hours The slower responses were in those patients who had profuse rhinorrhœa preventing the powder from being retained in more than small quantities

The later results were also very encouraging (table II) 19 patients were followed up for the whole season, and only 2 of these relapsed while taking hydrocortisone 9 of the successful patients had to take the powder until the end of the pollen season but had perfect control of their symptoms all the time they were taking it After the first five days' treatment most of these patients did not relapse immediately when the drug was withdrawn but remained free from symptoms for up to sixteen days When hydrocortisone was resumed, they responded and remained symptom-free for as long as they were taking it In the remaining 8 successful cases the patients discontinued hydrocortisone permanently after five to twenty days and remained satisfactorily controlled thereafter These patients tended to have a return of minimal symptoms but to a degree so slight as not to justify taking further hydrocortisone 6 of these 8 patients were on anti histamine substances and continued with them after stopping hydrocortisone

An unexpected and remarkable result was seen in the effect of hydrocortisone on the eye symptoms associated with rhinitis initially in all cases Itching and watering of the eyes and accompanying conjunctival injection disappeared in 20 of the 24 patients during their initial response A further point of interest was the behaviour of the 10 patients who previously had had pollen asthma every year in addition to hay-fever In 4 of them no chest symptoms developed, all being patients taking hydrocortisone to the end of the season It is likely that in these cases the part of the hydrocortisone which penetrated into the bronchi had a curative effect, as has been observed by Foulds et al (1955) The remaining 6 patients had their asthma as usual

There was no significant difference in the results between the group taking anti histamine substances and the others

Discussion

The initial response to this form of local hydrocortisone treatment was dramatic As could be expected, relapse occurred in some cases as soon as the treatment

TABLE II—LATE RESULTS

innocuous After considerable discussion in the correspondence columns of this journal Sykes (1955) declared: "I am aware of no work which suggests that nitrous oxide per se is dangerous." This statement, of course, applies only to the usual surgical use of nitrous oxide and not to its use over many days.

In view of the fact that our first 2 patients who recovered had shown signs of bone-marrow depression, and thus had proved that the hæmatological changes were not invariably fatal, it was felt permissible to try the effect of prolonged anæsthesia with nitrous oxide and oxygen under strict hæmatological control.

Clinical Trial of Nitrous-oxide Anæsthesia

On Sept. 1, 1955, a boy, aged 10 years, was admitted with severe tetanus.

Twelve days previously he had been run over by a tractor and had sustained a compound fracture of his right leg. Trismus and severe backache appeared ten days later, but despite this rather long incubation time severe tetanus developed with alarming rapidity.

On the day after admission respiration became inadequate through accumulation of secretion in the airway and incipient atelectasis, and tracheotomy had to be done. During the next two weeks the tetanus was kept in check with pentobarbitone given through an indwelling stomach tube. Because of the severity of the tetanus the dosage of the pentobarbitone had to be so large that spontaneous respiration failed and it became necessary to institute manual artificial respiration or to use a positive pressure machine.

Fig. 3 shows that during the first two weeks' treatment the leucocyte and thrombocyte counts and granulocyte percentage remained normal. General anæsthesia was then started with 50% nitrous oxide and 50% oxygen and immediately proved beneficial. The tetanus promptly became more easy to handle, and the dosage of sedatives was reduced.

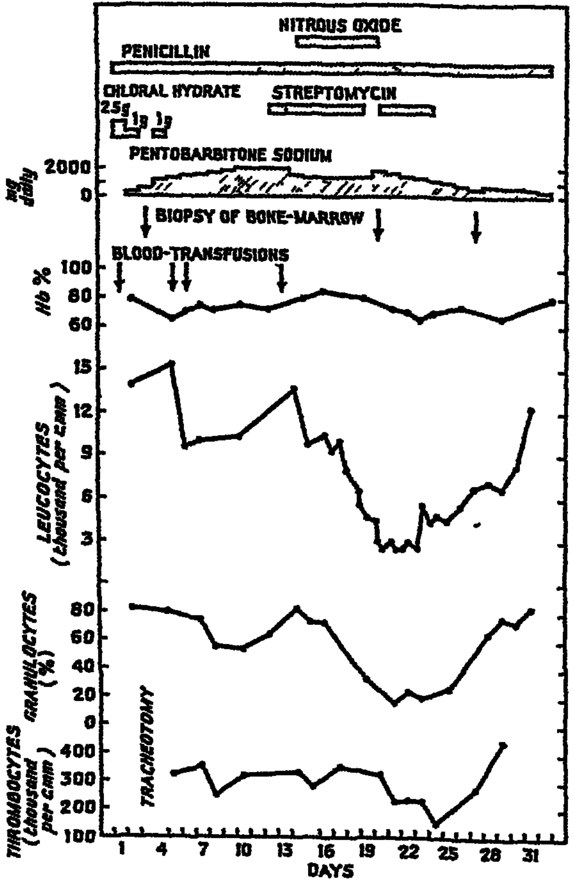

Fig. 3—Blood changes in a boy, aged 10 years, with tetanus.

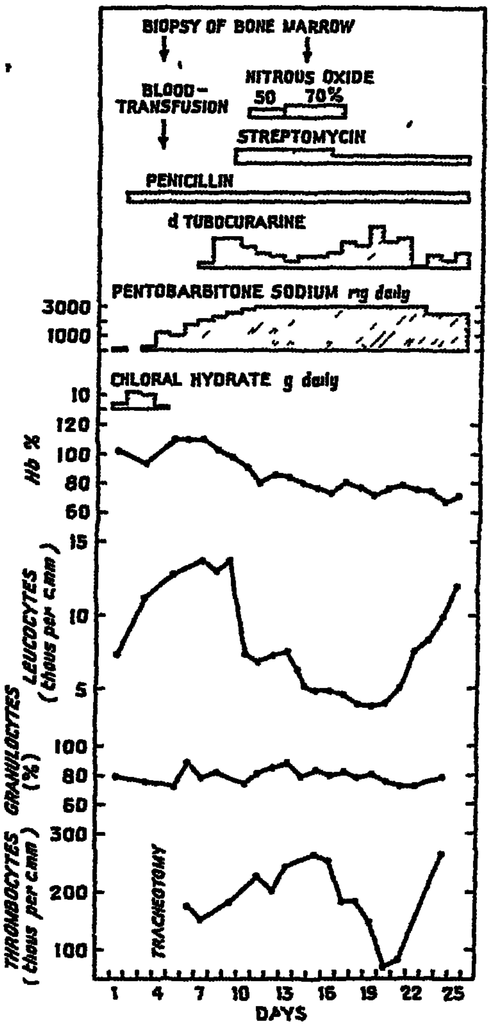

Fig. 4—Blood changes in a girl, aged 13, with tetanus.

On the fourth day of nitrous oxide anæsthesia the percentage of granulocytes decreased so sharply that next day the administration of nitrous oxide was discontinued. In the next few days a rather considerable decrease in the number of thrombocytes was also observed.

Bone marrow biopsy on the fifth day of anæsthesia revealed that erythropoiesis was strikingly megaloblastic and the changes in granulocytopoiesis were so pronounced and typical that, unless one knew the clinical history, one would not hesitate to diagnose pernicious anæmia.

After the anæsthetic had been discontinued we followed the course of the tetanus with apprehension although the boy's general condition was satisfactory. On the next three days the leucocyte counts remained low. The tetanus became active and the doses of sedatives had to be increased. On the fourth day, however, the number of leucocytes began to increase although transfusion and anti-pernicious anæmia drugs had not been given and the general regime remained unchanged. A few days later the white cell count was normal and bone marrow biopsy showed changes consistent with toxic infectious damage, and no signs of lack of anti-pernicious anæmia factor. The further course of the tetanus was uneventful, and the boy was transferred to the local hospital a few weeks later.

At this juncture Mollaret et al. (1955) published a severe case of tetanus in which agranulocytosis developed after the patient had been treated by tracheotomy and artificial respiration and with chlorpromazine, *d*-tubocurarine, and various sedatives, but no nitrous oxide anæsthesia. Only the white cells (especially the granulocytes) were involved; apart from this the bone marrow was normal (R. Bastin, personal communication).

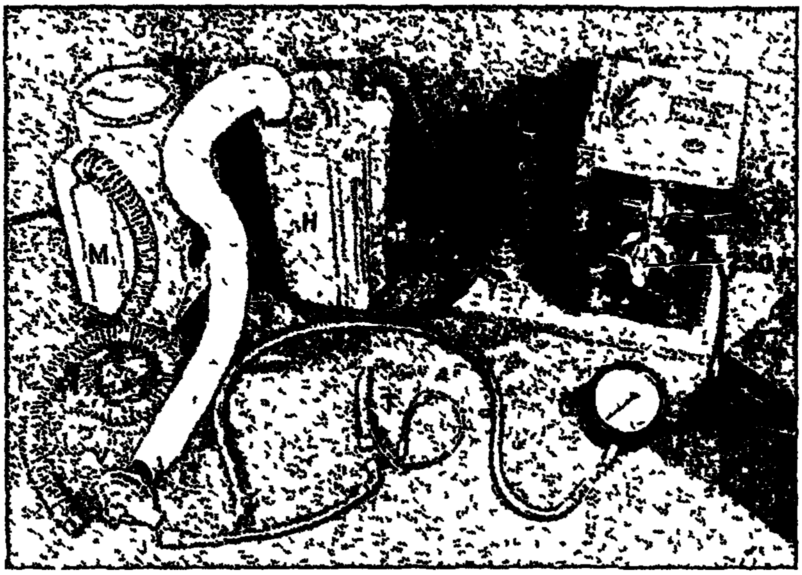

Fig 1—Radcliffe respiration pump in its most used form The items shown are the bellows (P), humidifier (H), Stott valve (V), tracheotomy tube (T), gas meter (M), pressure gauge (G), and 12-volt D C and 230 volt A C motors

Simple and Easy Hand Operation—A handle is inserted and turned at the appropriate speed No clutch is required to disconnect the motor, because there is a free wheel in the gear box, and the weight controlled wave form and pressure of delivery remain entirely uninfluenced by the operator's actions

Respiratory rate Control—For use with adults respiratory rates of 12, 16, 20, and 25 are available For young children an alternative sprocket is used in the drive to provide respiratory rates of 20, 23, 30, and 37

Oxygen Intake—Though oxygen is rarely used for these cases, a simple system is available whereby the continuous flow of oxygen from a cylinder meets the intermittent requirements of the positive pressure bellows, any required mixture of air and oxygen being easily provided This consists of a length of corrugated breathing tube, of which one end is open to the air and the other is attached to the pump intake Oxygen is led in at the pump end of this tube so that it accumulates in the tube to form a reservoir for each intake This device is seen below the bellows (P) in fig 2

Positive pressure control providing pressure from +10 to +30 cm water

Humidifier gauge showing the amount of water in the humidifier

Pressure Gauges—There are two pressure gauges, one reading from the inspiratory valve, the other from close to the patient Water traps are included to insure that water cannot reach and block the gauges

Removable trap in which secretions contained in the expired air are collected

A *gas meter* is incorporated and is switched in or out of the expiratory side of the circuit at will

Negative pressure control providing pressure from 0 to −10 cm water

Safety devices include a rod attached to each bellows (R in fig 2) and providing a visible indication of the bellows' action An audible and visible warning device will also be incorporated because the snore of the Stott valve has in practice proved a most effective safety device which is lost with cam operation of the valves The readings on the pressure gauges and gas meter provide additional safeguards, and if the patient can cooperate he can be provided with foot operated or chin operated switch for an electric bell

The complete apparatus is mounted on a trolley measuring 2 ft 6 in × 1 ft 8 in × 2 ft-6 in The trolley includes a folding shelf and an arm to support the tubes going to and from the patient Extra apparatus—e g, throat

Figs 2-4—Radcliffe positive negative respiration pump (side plates removed) showing main components positive-pressure bellows (P), negative pressure bellows (N), humidifier (H), cam-operated valves (V), gas-meter (M), and 12 volt D C and 230 volt A C motors

TABLE I—CLINICAL DATA

Case no	Sex	Age (yr)	Estimated duration of diabetes (yr)	Duration of vascular disease (retinopathy) (yr)	Albuminuria (g per litre)	"Severity" of diabetes (units of insulin)	Control (5 yr)
1	M	31	20	5	5	24	Brittle
2	M	49	20	13		40	Good
3	M	53	23	6?	4	30	Good
4	M	60	?	?	1	36	Good (1 year only)
5	F	57	20	2		16	Fair
6	F	53	?	?		52	Good (2 years only)

programme is simpler; (3) the preoperative and post-operative management of adrenalectomy was already well understood at the hospital to which the diabetic clinic was attached; and (4) intractable hypoglycæmia after hypophysectomy had been reported (E. B. C. Hughes, W. G. Oakley, personal communications).

Material

6 patients were subjected to total adrenalectomy for diabetic vascular disease at the General Hospital, Birmingham. The main facts are set out in tables I and II.

In case 1 there had for years been fluctuation between abnormally high and low blood-sugar levels, though ketosis requiring admission to hospital had only occurred once. Cases 2 and 3 had no glycosuria in fasting specimens, and the blood-sugar level at 2 P.M. was below 180 mg. per 100 ml. at each attendance. The duration of the retinopathy in case 3 was unknown because he only began to attend hospital six years before admission, when he already had retinopathy. Case 4 was only found to have diabetes two years before admission, when the retinal changes impaired his vision. Case 5 had been well controlled by dietetic restriction for the first fourteen years of her diabetes, but for the last six years only symptomatic control had been maintained. There was glycosuria in all specimens of her urine, and her average blood sugar level at 2 P.M. was 250 mg. per 100 ml. Case 6 had been treated for two years following the discovery of advanced retinopathy, though glycosuria had been first found twenty-eight years earlier.

TABLE II—FINDINGS BEFORE OPERATION

Case no	Stage of retinopathy (Ballantyne)	Albuminuria (g. per litre)	Blood-urea (mg. per 100 ml.)	Blood pressure (mm. Hg)	Indication for operation
1	3	8	220	180/110	Retinopathy failing vision
2	3	0	39	150/80	Retinopathy vitreous hæmorrhages
3	4	5	50	200/100	Retinopathy vitreous hæmorrhages albuminuria
4	4	2	41	200/100	Retinopathy failing vision albuminuria
5	3	0	38	210/130	Retinopathy vitreous hæmorrhages
6	3	0	28	140/80	Retinopathy failing vision

Retinopathy is graded by Ballantyne's classification: (1) micro aneurysms singly or in small numbers near the macula; (2) blot hæmorrhages and confluent waxy exudates; (3) addition of venous changes—tortuosity, loops, coils, and plexuses on the anterior surface of the retina or in the vitreous; and (4) intraocular hæmorrhage preventing ophthalmoscopy, blindness, and perhaps glaucoma. In cases 1, 3, and 4 there was no reason to doubt that the hypertension was renal in origin. In case 5 a gradual rise of blood-pressure had been noted throughout ten years; there was a family history of high blood-pressure, and the hypertension was regarded as "essential."

Operations

All the operations were done by Mr. J. A. C. Edwards in two stages by the lumbar approach, and in every case the adrenal glands were believed to have been removed entire. The preoperative and postoperative routines were the same in every case and were applied to both the first and the second stages.

(1) Soluble insulin in divided doses was used for three days before the operation to avoid any depot effect of long acting preparations. On the morning of the operation soluble insulin in a dose of a third of the normal daily total was given with glucose 30 g. three hours before the operation. On the day following the operation a dose of a quarter of the normal daily total was given, and on the second postoperative day treatment with delay insulin was resumed.

TABLE III—RESULTS OF OPERATION

Case no	Follow up	General state	Diabetic control	Retinopathy	Albuminuria	Insulin (units) Before	Insulin (units) After
1	2 weeks (died)					24	
2	16 months	Better	Unchanged	Better	Unchanged	40	44
3	9 months	Unchanged	Unchanged	Unchanged	Unchanged	36	20
4	11 months	Unchanged	Unchanged	Unchanged		36	44
5	9 months	Unchanged	Better	Worse		16	16
6	5 months	Unchanged	Unchanged	Unchanged		52	48

(2) Twelve hours before the operation intramuscular cortisone 200 mg. was given and 50 mg. by the same route six hourly for the following forty eight hours. Cortisone 25 mg. was given orally three hours before the operation, then no more until the second postoperative day, when four doses of 25 mg. were given, the dosage thereafter being gradually decreased to 50 mg. daily.

(3) During the operation and the following twenty four hours an intravenous infusion of 4 pints of physiological saline solution was given. Glucose was not used, because it makes estimations of the blood sugar useless. By the second day a full diet was resumed, and thereafter no special modification of the diet was used.

Results

The major effects of the operations are set out in tables III and IV. "General state" refers to the sense of well being, maintenance of body weight, and capacity to work. The improvement in case 2 partakes of all these features, with a return to normal visual acuity

TABLE IV—FINDINGS AFTER OPERATION

Case no	Stage of retinopathy Before	Stage of retinopathy After	Albuminuria (g. per litre) Before	Albuminuria (g. per litre) After	Blood urea (mg. per 100 ml.) Before	Blood urea (mg. per 100 ml.) After	Blood pressure (mm. Hg) Before	Blood pressure (mm. Hg) After
1	3		8		220		180/110	
2	3	3	0	0·0	39	35	150/80	120/80
3	4	3	5	5·0	50	40	200/100	150/80
4	4	4	2	1·8	41	45	200/100	180/80
5	3	4	0	0·0	38	28	210/130	150/80
6	3	3	0	0·0	28	30	140/80	130/80

know which specimen belonged to a given patient, whether it was fresh or 24 hours old, and whether or not it had been already estimated the previous day The results could only be interpreted when the key to the many names used was consulted In this way it was possible to check the accuracy of the estimations and to find out what effect 24 hours' delay had on the results

No statistical study was made, but table I shows that there is a close relationship between the two sets of readings There are minor variations, partly due to the control time varying on successive days, but in practice either result could have been used to maintain satisfactory control of the treatment

Further tests were done to find out if there was a difference in the delayed estimation when plasma was used instead of whole blood The specimen was obtained by spinning the blood immediately after withdrawal and, together with a sample of whole blood, posted as outlined above The results obtained were once again very similar and are shown in table II, suggesting that the extra trouble and apparatus required to obtain the plasma were unnecessary

It had previously been suggested (J A Tulloch, personal communication) that the best method of obtaining a prothrombin time, when an immediate test could not be made, was to put the plasma on ice So an experiment was made exactly as before with the samples of whole blood and plasma duplicated Two were sent through the post and two were kept in the refrigerator for 24 hours before estimation Table III shows that there was little difference in the one stage prothrombin times, which were again, from a therapeutic point of view, almost identical with those of the sample estimated immediately after withdrawal

TABLE II—EFFECT ON DELAYED ONE STAGE PROTHROMBIN TIME OF PLASMA COMPARED WITH WHOLE BLOOD

Case no	Whole blood						Plasma 24 hr later

Finally the effect of hæmolysis was investigated Many of the routine samples arriving at the laboratory from the wards were hæmolysed, and it was the practice to request a fresh specimen in such cases In view of this the plasma used in the above mentioned tests was examined spectroscopically, and any specimen showing more than a faint trace of hæmolysis was discarded from the series

It was decided to study the effect of deliberate hæmolysis in the duplicate sample This was found to be very difficult to achieve, at least by mechanical means High pressure ejection from the syringe through a small bore needle followed by vigorous shaking of the tube was successful in a few cases Hæmolysis produced in this way had no significant effect on either the immediate or the delayed one stage prothrombin time (table IV) It was thought probable that contamination by either *methylated ether or surgical spirit might be responsible* for the hæmolysis commonly seen , so a group was tested in which one drop of surgical spirit had been deliberately added to the duplicate sample This produced gross hæmolysis in every case, and the close relationship noted between the two sets of results in all previous experiments was no longer found (table V)

Discussion

The care of patients on prolonged anticoagulant therapy involves far more than adjustment of their daily dose of coumarin drug, and their supervision must remain in the hands of experienced physicians It therefore remains necessary for them to report back to the main

TABLE III—EFFECTS OF ROOM-TEMPERATURE AND OF REFRIGERATION ON DELAYED ONE STAGE PROTHROMBIN TIME OF WHOLE BLOOD AND PLASMA

retina, which he described, is now generally accepted, and one may follow his classifications as follows:

(1) Changes chiefly in the central area, micro aneurysms with or without punctate hæmorrhages and punctate exudates

(2) Dot and blot hæmorrhages, confluent waxy exudates

(3) Changes in the veins (newly formed intraretinal and preretinal veins, phlebitis and phlebosclerosis, and the formation of knots, coils and loops in the distended veins), increasing hæmorrhages in the retina and vitreous, massive exudates retinitis proliferans, and detachment of the retina

(4) A further advance in the vessel changes, with increase in vitreous hæmorrhages and exudates, and destruction of the retina

ittle has been written about the duration of these ges and their prognosis, though Ballantyne does not isider them necessarily a sequence of progressive anges For example, stage 1 may pass directly to age 3 Ballantyne noted that in stage 1 micro neurysms may disappear Dolger (1947), who believed hat the rate of progression of retinopathy was not elated to the severity of the diabetes or its control, observed that retinal hæmorrhages often resolved spontaneously, but that retinitis proliferans often progressed to blindness within a year Work referring to the earlier stages of retinopathy by Wagener (1945), Bartels and Poulsen (1950), Scott (1951), and Vogelius (1949) is concerned mainly with the incidence of retinopathy in diabetic populations It seems certain that retinopathy will develop in every diabetic who lives long enough, and that the final stage of blindness will arrive in those who do not succumb to renal failure before their sight fails, but the thirty or forty years' follow-up which would show this is not yet possible

We are here concerned with the tempo of retinopathy and with the prognosis attached to the findings in any given case In Ballantyne's stage 1 the finding of micro- neurysms alone may be repeated, without deterioration nd even with transient improvement for several years The longest duration of this stage in my records is nine years In stage 2 it is usual for the changes to progress within five years to gross visual impairment Of 19 patients personally observed, in whom the entry into stage 2 could be estimated within six months, 15 were seriously hampered by reduced visual acuity after five years There are, however, striking exceptions, of which the following is a fair example

A man developed diabetes at the age of 25 At 43 he complained of poor vision. His visual acuity was corrected to 6/6 in each eye, but stage-2 retinopathy was found At the age of 48 his visual acuity was corrected only to 6/12 and the retinopathy was more extensive At the age of 50 his visual acuity was again corrected to 6 6 in each eye and the retinopathy was less obvious

Usually the younger the patient the greater is the chance of a benign course in stage 2 In stage 3 the visual prognosis is very poor, and cases like the following 2 are quite exceptional

A woman had diabetes diagnosed at the age of 25 with poor sion and stage 2 retinopathy At the age of 38 vision of her ght eye was suddenly blurred by big vitreous hæmorrhages, wo months later she had a similar episode in her left eye Both eyes cleared to visual acuity 6/12 She had no further complaint of vision At the age of 50 she is at work as a housekeeper and can read normal print and sew

A man developed diabetes at the age of 22 At the age of 34 he was found to have stage-1 retinopathy, but he had no visual impairment until he had a big vitreous hæmorrhage at the age of 47 He had two other hæmorrhages in the same year, and all of them resolved At the age of 53 his visual acuity is 6/12, and he is working as a bank cashier

The expectation of useful vision in retinitis proliferans has nowhere been clearly stated Dolger (1947) emphasised the unpredictable nature of retinopathy and the rapidity with which it may proceed to blindness Root (1952) reports the duration of retinitis proliferans in 326 cases in 124 patients who had died the average duration of retinitis proliferans was three years for males and four years for females Of the 124 deaths 66 were due to renal disease So far only 25 of the living were known to have become completely blind Root believes that associated renal or cardiac disease usually leads to death before blindness is complete This seems to be true, but exceptions are not rare, as in the following cases

A boy had diabetes at the age of 19 but maintained perfect health until at the age of 33 he began to have vitreous hæmorrhages, which left him blind at the age of 35 At the age of 41 he remains otherwise well and has no albuminuria

A woman, who had been treated for diabetes from the age of 30 became blind from retinopathy at the age of 54 She remained otherwise well with no albuminuria, and died suddenly from coronary thrombosis at the age of 62

Dolger (1947) found that 50% of his patients had hypertension and 30% albuminuria at the onset of the earliest retinal lesions Since he did not use mydriatics in examining the eyes he may well have missed minor lesions for a time, with the result that his estimates are perhaps unduly high In 50 consecutive cases in which the diabetes came on under the age of 50 (as in Dolger's series) with retinopathy but no visual symptoms, the lesions being therefore classified as early, I found hypertension in 26% and albuminuria in 14% However, with more advanced retinopathy, as Root (1952) has shown, the chances of renal disease are much increased

Course of Glomerulosclerosis

The first clinical manifestation of glomerulosclerosis is albuminuria The earliest lesions are almost certainly present for months or years before this finding but remain symptomless, like those in the retina Under the stress of ketosis an impaired capacity to adjust electrolyte balance may occasionally be noted as evidence of renal damage before albuminuria is found on routine examination The albuminuria is at first intermittent, this has been so in every one of the 17 cases observed throughout the course of the disease by me and is noted by Wilson et al (1951)

The later syndrome is subject to some disagreement Kimmelstiel and Wilson's (1936) first patients had hypertension, massive œdema, heavy albuminuria, and renal insufficiency, and several workers (Kimmelstiel and Wilson 1936, Newburger and Peters 1939, Mauser et al 1942) subsequently correlated this clinical picture with the histological findings of glomerulosclerosis though the lesions were noted by some workers to be much more common than the syndrome Henderson et al (1947) listed, as the clinical features, a long duration of the diabetes, hypertension, albuminuria, renal insufficiency, and mixed diabetic and hypertensive retinopathy The œdema was omitted In my 17 cases both pictures have been seen, but œdema appeared during the course of the illness in 14, the 3 other patients died of coronary-artery disease, perhaps before the stage of œdema On the other hand, it must be admitted that some patients with glomerulosclerosis may have escaped diagnosis because of the presence of renal infection or because of there being no necropsy The inconsistencies in description of the clinical features seem to be mainly due to difference in the patients' ages the nephrotic picture predominates in the young, whereas in the elderly there may be no distinctive signs, though diffuse changes are found post mortem

Once again we are here concerned mainly with the prognostic significance of the clinical features It seems clear that the appearance of albuminuria in a patient with long-standing diabetes, unless it can be attributed to active urinary infection or to gross cardiac insufficiency, indicates the onset of glomerulosclerosis Chronic pyelonephritis with secondary hypertension may confuse

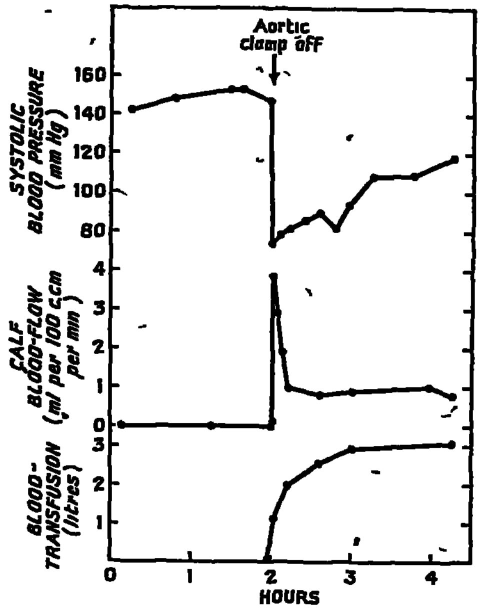

Fig 2—Systolic blood pressure, calf blood flow, and blood-transfusion during resection of aortic aneurysm Aorta clamped above the renal vessels, and bifurcation prosthesis inserted

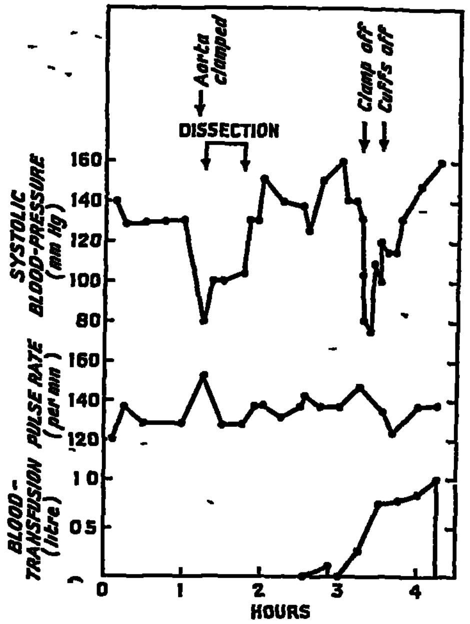

Fig 3—Systolic blood-pressure and blood transfusion during resection of high aortic thrombosis Aorta clamped below renal vessels, and Orlon bifurcation prosthesis inserted

re-established in a relatively limited area of ischæmic tissue through the internal iliac, inferior epigastric, and circumflex femoral arteries, and possibly the upper profunda femoral anastomosis When the blood-pressure has recovered from the fall so incurred, the thigh cuffs are deflated one after the other The time for this procedure seldom exceeds twenty minutes

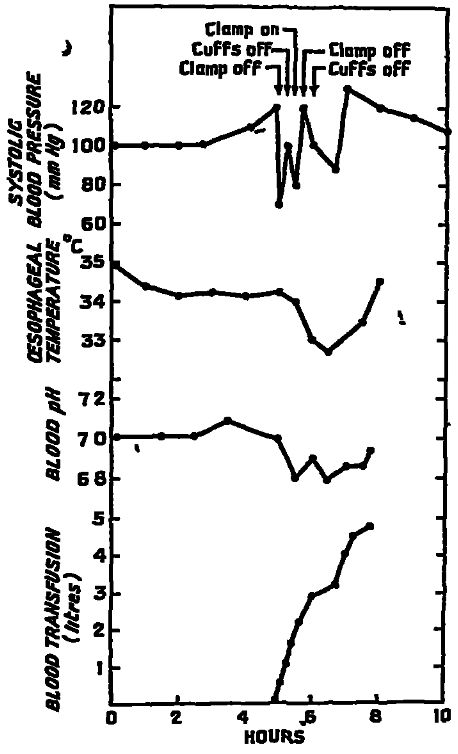

Fig 4—Systolic blood pressure, œsophageal temperature, pH of blood in inferior vena cava, and blood-transfusion in resection of abdominal aneurysm Aorta clamped below renal vessels, and bifurcation prosthesis inserted

This controlled re-establishment of blood-flow appears to limit the degree and duration of hypotension Of 7 patients so managed 1 died from coronary occlusion on the third post-operative day In addition, only 1 patient in this series has received a noradrenaline infusion during the period of hypotension

Figs 3 and 4 are representative charts of patients in this series and show the fall of systolic pressure resulting from release of the aortic clamp and the cuffs It often happens that release of the second cuff only delays the rise in pressure Fig 4 is of particular interest because samples of blood were taken from a catheter placed in the inferior vena cava The blood pH and the plasma-potassium level were estimated and recorded, The lowest pH determined was 6·79 and the highest K+ 8·5 m.eq per litre, the K+ curve being a mirror image of the pH curve This was probably due to an inadvertent rapid infusion of 3·8 litres of stored blood after an unexpected hæmorrhage Stored blood may have a pH as low as 6·4 and a plasma potassium level as high as 8·7 m.eq per litre Because of these properties of stored blood our practice is to obtain a high proportion of the total blood used in these cases fresh from the donor.

The body-temperature was recorded with an œsophageal thermocouple placed at heart level and showed the fall of temperature resulting from re-established circulation in the ischæmic tissues and the infusion of cool blood

Conclusion

Release of the circulation in operations for grafting segments of aorta suddenly increases the blood flow in the legs to two or three times the resting level and considerably more than the very small flow when the aorta is occluded There is also refilling of a partially emptied limb vascular bed This "physiological hæmorrhage" may explain the hypotension observed, but possibly the sudden addition to the general circulation of vasodilator metabolites produced by the ischæmic tissues may contribute to it Large infusions of whole blood and often of noradrenaline are required to compensate the fall in blood pressure, with a resultant increase in the blood volume in the early postoperative period, thus placing an additional strain on the heart —a matter of some consequence in patients with atherosclerosis

The use of thigh cuffs to permit a *controlled* release of the circulation appears to have limited the degree and duration of the hypotension in the cases reviewed From observation of other patients in whom the aorta has been clamped at various levels for one or two hours, the cuffs appear to be of most value in the following circumstances (1) when the aorta has been clamped proximally, (2) where a long segment of aorta is occluded, and (3) where there is little or no established collateral circulation

Summary

Release of the aortic clamp in operations for grafting segments of the aorta causes a profound fall in blood pressure

A striking increase in calf blood-flow accompanies this hypotension

A simple apparatus is described which allows a more controlled re-establishment of the circulation in such cases

Attention is drawn to the potential danger of a rapid infusion of large quantities of stored blood

retina, which he described, is now generally accepted, and one may follow his classifications as follows

(1) Changes chiefly in the central area, micro aneurysms with or without punctate hæmorrhages and punctate exudates

(2) Dot and blot hæmorrhages, confluent waxy exudates

(3) Changes in the veins (newly formed intraretinal and preretinal veins, phlebitis and phlebosclerosis, and the formation of knots, coils, and loops in the distended veins), increasing hæmorrhages in the retina and vitreous, massive exudates, retinitis proliferans, and detachment of the retina

(4) A further advance in the vessel changes, with increase in vitreous hæmorrhages and exudates, and destruction of the retina

Little has been written about the duration of these stages and their prognosis, though Ballantyne does not consider them necessarily a sequence of progressive changes For example, stage 1 may pass directly to stage 3 Ballantyne noted that in stage 1 micro aneurysms may disappear Dolger (1947), who believed that the rate of progression of retinopathy was not related to the severity of the diabetes or its control, observed that retinal hæmorrhages often resolved spontaneously, but that retinitis proliferans often progressed to blindness within a year Work referring to the earlier stages of retinopathy by Wagener (1945), Bartels and Poulsen (1950), Scott (1951), and Vogelius (1949) is concerned mainly with the incidence of retinopathy in diabetic populations It seems certain that retinopathy will develop in every diabetic who lives long enough, and that the final stage of blindness will arrive in those who do not succumb to renal failure before their sight fails, but the thirty or forty years' follow up which would show this is not yet possible

We are here concerned with the tempo of retinopathy and with the prognosis attached to the findings in any given case In Ballantyne's stage 1 the finding of micro-aneurysms alone may be repeated, without deterioration and even with transient improvement for several years The longest duration of this stage in my records is nine years In stage 2 it is usual for the changes to progress within five years to gross visual impairment Of 19 patients personally observed, in whom the entry into stage 2 could be estimated within six months, 15 were seriously hampered by reduced visual acuity after five years There are, however, striking exceptions, of which the following is a fair example

A man developed diabetes at the age of 25 At 43 he complained of poor vision His visual acuity was corrected to 6/6 in each eye, but stage 2 retinopathy was found At the age of 48 his visual acuity was corrected only to 6/12 and the retinopathy was more extensive At the age of 50 his visual acuity was again corrected to 6/6 in each eye and the retinopathy was less obvious

Usually the younger the patient the greater is the chance of a benign course in stage 2 In stage 3 the visual prognosis is very poor, and cases like the following 2 are quite exceptional

Once again we are here concerned mainly with the prognostic significance of the clinical features It seems clear that the appearance of albuminuria in a patient with long standing diabetes, unless it can be attributed to active urinary infection or to gross cardiac insufficiency, indicates the onset of glomerulosclerosis Chronic pyelonephritis with secondary hypertension may confuse

TABLE I—COMBINED RATING SCORES FOR 33 ANXIETY-NEUROTICS RECEIVING DIFFERENT DRUGS (A LOW SCORE INDICATES A FAVOURABLE RESPONSE)

Symptom or sign	How often rated	Rated by	Total score for week on		
			Reserpine	Amylobarbitone sodium	Control substance
General condition	Daily	Patient	221	155	212
	,,	Nurse	231	147	189
	Weekly	Patient	60	33	58
	Bi weekly	Physician	119	74	105
Headache	Daily	Patient	262	184	264
Indigestion	,,	,,	172	104	162
Palpitation	,,	,,	197	118	192
Sweating	,,	,,	121	78	129
Trembling	,,	,,	372	171	243
Dizziness	,,	,,	276	196	213
Drowsiness	,,	,,	360	293	272
Depression	,,	,,	352	269	336
Anxiety and tension	,,	,,	365	267	343
	Bi weekly	Physician	180	142	165
Other somatic signs	Bi weekly	,,	84	52	65
Sleep	Weekly	Patient	29	27	38
	Daily	,,	208	166	238
	,,	Nurse	722	714	829

nurse of the ward kept an independent daily record in which he assessed each patient's daily condition as "improved," "same," or "worse" (scored 0–2) The night-nurse kept a sleep chart recording the number of half-hourly periods between 10 P M and 6 30 A M that the patient was observed to be awake (scored 1 for each half-hour awake) The physician in charge of the case recorded twice weekly

(1) His assessment of the patient's general clinical condition compared with the previous period—from "much improved" to "much worse" (scored 0–4)

(2) The presence of anxiety, tension and other somatic signs—"absent," "slight," "moderate," or "severe" (scored 0–3)

(3) The patient's blood-pressure, measured under standard conditions

Finally, at the conclusion of each patient's trial but before he knew the order in which the drugs had been given, the physician rated each weekly period as better, equal to, or worse than each of the other two weekly periods

Results

Table I shows the totals of the scores obtained from 33 patients Since a low score means a good clinical response, it is clear that on the whole the patients felt better, both generally and for particular symptoms, when receiving amylobarbitone sodium than when receiving either reserpine or the control substance It is also clear that there is little or no difference between the response to reserpine and that to the control substance

Table II compares the weekly periods on the different drugs, assessed by the physician at the completion of the trial Evidently there is nothing to choose between the effects of reserpine and of the control substance The periods on amylobarbitone sodium, however, are for the most part better *than either those on reserpine* or those on the control substance, the expected proportion of "*better*" periods on amylobarbitone sodium (on the null hypothesis) lies in each case outside the 90% confidence limits of the observed proportion

TABLE II—NUMBER OF TIMES THE GENERAL CLINICAL CONDITION OF THE PATIENTS RECEIVING THE FIRST NAMED DRUG WAS BETTER, EQUAL TO, OR WORSE THAN THEIR CONDITION WHEN RECEIVING THE SECOND NAMED DRUG

Drugs	Comparative clinical response		
	Better	*Equal*	Worse
Reserpine *v* control substance	15	3	15
Amylobarbitone sodium *v* control substance	27	1	5
Amylobarbitone sodium *v* reserpine	25	1	7

Comparison of the blood-pressure readings for different weeks of the trial gave (for 29 patients only) the following mean values

	Reserpine	*Amylobarbitone sodium*	*Control substance*
Systolic pressure (mm Hg)	127 5	130 2	13[illegible] 5
Diastolic pressure (mm Hg)	72 3	76 2	79 [illegible]

The systolic pressures were lower during the reserpine week than during the control week in 24 of the 29 patients, and the diastolic pressures were lower in 21 of them These figures suggest that reserpine was exerting a definite, if slight, hypotensive effect

The principal side effects—i e, new or troublesome *symptoms—noticed by the patients* are shown below, together with the number who mentioned them while receiving the different drugs

Symptom	*Reserpine*	*Amylobarbitone sodium*	*Control substance*
Drowsiness	11	7	3
Dizziness	8	6	4
Nasal congestion	6	—	—
Swelling of ankles	2	1	1
Increased appetite	2	—	1
Dyspepsia	2	1	1
Headache	1	—	—
Nightmares	2	1	2

Objectively there were no obvious signs attributable to the drugs, no parkinsonian rigidity was observed The occurrence of side effects in patients receiving inert control substances is, of course, well recognised (Wolf and Pinsky 1954)

Discussion

The effects of drug treatment in an anxiety state are possibly best assessed by the self-observation, under controlled conditions, of a cooperative and intelligent patient making a comparative rather than an absolute assessment of the intensity of his symptoms Bias due to casual environmental factors or to apparently spontaneous fluctuations in the degree of anxiety can, to a great *extent, be eliminated by using a blind self* controlled technique and a reasonably large series of cases A further advantage of the self-controlled and *self recorded* clinical trial is that it enables the reliability of the patients' records to be checked We may summarise the evidence which tends to confirm the reliability of the patients' records in the present trial as follows

(1) The patient's scores on different drugs are closely paralleled both by those of the charge nurses and those of the physicians

(2) The sleep assessments are mutually consistent

(3) The only instance in which a score on amylobarbitone sodium exceeds that on the control substance *is for* the patients' daily rating of "drowsiness," and thus corresponds to expectation Again, although for the most part there is little difference between the scores on reserpine and those on the control substance, the reserpine scores for "drowsiness," "dizziness," and "trembling"—all recognised side effects of reserpine treatment—are much higher

As regards the duration for which the drugs were exhibited in the present trial, it might be objected that a week is not *long enough for reserpine to exert* an adequate effect However, there is ample evidence that the reserpine was exerting its action in producing side effects, as well as its probable effect in lowering blood pressure (the hypotensive effect of reserpine in normotensive people has been demonstrated by Freis and Ari [1954]) It seems unlikely that the effect of a drug on anxiety could be delayed for more than a week when its other effects are manifest within a day or two Moreover, amylobarbitone sodium, which *also* caused side effects within a day or two, could clearly influence the mental state within the same short period

A more cogent criticism of the present findings is that any possible benefit from reserpine was offset by the unpleasant side effects associated with the rather high dosage used That these side effects could be trouble-retina, which he described, is now generally accepted, and one may follow his classifications as follows:

(1) Changes chiefly in the central area; micro aneurysms with or without punctate hæmorrhages and punctate exudates.

(2) Dot and blot hæmorrhages; confluent waxy exudates.

(3) Changes in the veins (newly formed intraretinal and preretinal veins; phlebitis and phlebosclerosis; and the formation of knots, coils, and loops in the distended veins); increasing hæmorrhages in the retina and vitreous; massive exudates; retinitis proliferans; and detachment of the retina.

(4) A further advance in the vessel changes with increase in vitreous hæmorrhages and exudates, and destruction of the retina.

Little has been written about the duration of these stages and their prognosis, though Ballantyne does not consider them necessarily a sequence of progressive changes. For example, stage 1 may pass directly to stage 3. Ballantyne noted that in stage 1 micro-aneurysms may disappear. Dolger (1947), who believed that the rate of progression of retinopathy was not related to the severity of the diabetes or its control, observed that retinal hæmorrhages often resolved spontaneously, but that retinitis proliferans often progressed to blindness within a year. Work referring to the earlier stages of retinopathy by Wagener (1945), Bartels and Poulsen (1950), Scott (1951), and Vogelius (1949) is concerned mainly with the incidence of retinopathy in diabetic populations. It seems certain that retinopathy will develop in every diabetic who lives long enough, and that the final stage of blindness will arrive in those who do not succumb to renal failure before their sight fails, but the thirty or forty years' follow-up which would show this is not yet possible.

We are here concerned with the tempo of retinopathy and with the prognosis attached to the findings in any given case. In Ballantyne's stage 1 the finding of micro-aneurysms alone may be repeated, without deterioration and even with transient improvement for several years. The longest duration of this stage in my records is nine years. In stage 2 it is usual for the changes to progress within five years to gross visual impairment. Of 19 patients personally observed, in whom the entry into stage 2 could be estimated within six months, 15 were seriously hampered by reduced visual acuity after five years. There are, however, striking exceptions, of which the following is a fair example.

A man developed diabetes at the age of 25. At 43 he complained of poor vision. His visual acuity was corrected to 6/6 in each eye, but stage 2 retinopathy was found. At the age of 48 his visual acuity was corrected only to 6/12 and the retinopathy was more extensive. At the age of 50 his visual acuity was again corrected to 6/6 in each eye and the retinopathy was less obvious.

Usually the younger the patient the greater is the chance of a benign course in stage 2. In stage 3 the visual prognosis is very poor, and cases like the following 2 are quite exceptional.

A woman had diabetes diagnosed at the age of 25 with poor vision and stage-2 retinopathy. At the age of 38 vision of her right eye was suddenly blurred by big vitreous hæmorrhages; two months later she had a similar episode in her left eye. Both eyes cleared to visual acuity 6/12. She had no further complaint of vision. At the age of 50 she is at work as a housekeeper and can read normal print and sew.

A man developed diabetes at the age of 22. At the age of 34 he was found to have stage-1 retinopathy, but he had no visual impairment until he had a big vitreous hæmorrhage at the age of 47. He had two other hæmorrhages in the same year, and all of them resolved. At the age of 53 his visual acuity is 6/12, and he is working as a bank cashier.

The expectation of useful vision in retinitis proliferans has nowhere been clearly stated. Dolger (1947) emphasised the unpredictable nature of retinopathy and the rapidity with which it may proceed to blindness. Root (1952) reports the duration of retinitis proliferans in 326 cases: in 124 patients who had died the average duration of retinitis proliferans was three years for males and four years for females. Of the 124 deaths 66 were due to renal disease. So far only 25 of the living were known to have become completely blind. Root believes that associated renal or cardiac disease usually leads to death before blindness is complete. This seems to be true, but exceptions are not rare, as in the following cases.

A boy had diabetes at the age of 19 but maintained perfect health until at the age of 33 he began to have vitreous hæmorrhages, which left him blind at the age of 35. At the age of 41 he remains otherwise well and has no albuminuria.

A woman, who had been treated for diabetes from the age of 30, became blind from retinopathy at the age of 54. She remained otherwise well with no albuminuria, and died suddenly from coronary thrombosis at the age of 62.

Dolger (1947) found that 50% of his patients had hypertension and 30% albuminuria at the onset of the earliest retinal lesions. Since he did not use mydriatics in examining the eyes he may well have missed minor lesions for a time, with the result that his estimates are perhaps unduly high. In 50 consecutive cases in which the diabetes came on under the age of 50 (as in Dolger's series) with retinopathy but no visual symptoms, the lesions being therefore classified as early, I found hypertension in 26% and albuminuria in 14%. However, with more advanced retinopathy, as Root (1952) has shown, the chances of renal disease are much increased.

Course of Glomerulosclerosis

The first clinical manifestation of glomerulosclerosis is albuminuria. The earliest lesions are almost certainly present for months or years before this finding but remain symptomless, like those in the retina. Under the stress of ketosis an impaired capacity to adjust electrolyte balance may occasionally be noted as evidence of renal damage before albuminuria is found on routine examination. The albuminuria is at first intermittent; this has been so in every one of the 17 cases observed throughout the course of the disease by me and is noted by Wilson et al. (1951).

The later syndrome is subject to some disagreement. Kimmelstiel and Wilson's (1936) first patients had hypertension, massive œdema, heavy albuminuria, and renal insufficiency; and several workers (Kimmelstiel and Wilson 1936, Newburger and Peters 1939, Mauser et al. 1942) subsequently correlated this clinical picture with the histological findings of glomerulosclerosis, though the lesions were noted by some workers to be much more common than the syndrome. Henderson et al. (1947) listed, as the clinical features, a long duration of the diabetes, hypertension, albuminuria, renal insufficiency, and mixed diabetic and hypertensive retinopathy. The œdema was omitted. In my 17 cases both pictures have been seen, but œdema appeared during the course of the illness in 14; the 3 other patients died of coronary-artery disease, perhaps before the stage of œdema. On the other hand, it must be admitted that some patients with glomerulosclerosis may have escaped diagnosis because of the presence of renal infection or because of there being no necropsy. The inconsistencies in description of the clinical features seem to be mainly due to difference in the patients' ages: the nephrotic picture predominates in the young, whereas in the elderly there may be no distinctive signs, though diffuse changes are found post mortem.

Once again we are here concerned mainly with the prognostic significance of the clinical features. It seems clear that the appearance of albuminuria in a patient with long-standing diabetes, unless it can be attributed to active urinary infection or to gross cardiac insufficiency, indicates the onset of glomerulosclerosis. Chronic pyelonephritis with secondary hypertension may confuse

CASES OF ACUTE PORPHYRIA

Case	Sex	Age (yr)	Medication	Neurological complications	Outcome
4 (1st attack)	M	20	0 5 g thiopentone for laparotomy	None	Recovered
(2nd ,,)			Gr 3 quinalbarbitone	Paralysis of both arms ten days later	Recovered
6 (1st attack)	F	21	Thiopentone for appendicectomy	None	Recovered
(2nd ,,)			Thiopentone for laparotomy, and gr $1\frac{1}{2}$ butobarbitone daily for six days afterwards	None	Recovered
(3rd ,,)			Gr 20 barbitone sodium and gr 4 phenobarbitone for several days in a mental hospital	Complete paralysis of both arms and legs	Died
8 (several attacks)	F	59	Large doses of various barbiturates at mental hospitals	None	Died (from carcinoma of stomach)
9	F	36	Gr 1 phenobarbitone and gr 3 quinalbarbitone daily for four days	Paralysis of arms fourteen days later	Recovered
10	F	55	Gr 1 phenobarbitone and gr 3 quinalbarbitone daily for seven days	Paralysis of both arms and legs	Died
11	F	21	0 5 g thiopentone for laparotomy followed by gr 2 phenobarbitone for fourteen days	Paralysis of both arms and legs seventeen days after laparotomy	Died, 8 weeks pregnant
12	M	58	Gr 2 phenobarbitone daily for a month before attack	None	Recovered
13	F	44	0 5 g thiopentone for laparotomy, gr $\frac{1}{2}$ phenobarbitone and gr $1\frac{1}{2}$ butobarbitone for six days after operation	None	Recovered

If it is not possible to carry out the test shortly after the urine has been passed, it should be stored in the dark and tested within twenty-four hours

In addition to porphobilinogen, the urine of patients with latent or acute porphyria may contain porphyrins, which can be detected by the 2 following techniques

Ultraviolet fluorescence—A filtered urine, preferably after standing overnight, is examined under ultraviolet light with a Wood's glass filter A distinctive red to salmon pink fluorescence indicates the presence of porphyrins To show the fluorescence more clearly, the porphyrins may be concentrated in an amyl alcohol extract of urine acidified with a few drops of acetic acid

Spectroscopic examination with the dark-vision spectroscope shows two bands at 577 and 541 mμ These are due to a porphyrin-metal complex and are very similar to the bands of oxyhæmoglobin, but if the urine is made strongly acid by adding 25% *v/v* of concentrated hydrochloric acid, a porphyrin spectrum may be seen at 597 and 553 mμ It is advisable to test various depths of urine, because a poor spectrum may be obtained with too much or too little urine

Further differentiation of the porphyrins into the various isomers and quantitative determination has proved of little value in the diagnosis of acute porphyria

During the past two years, all urines sent to the laboratory have been tested for porphobilinogen and we have been rewarded by finding 2 cases of acute porphyria case 12 was being treated at home by his practitioner for abdominal pain, and case 13 was in a surgical ward recovering from a cholecystectomy which had failed to relieve her pain

Hammond and Welcker (1948) carried out a similar investigation of the urines of 1000 patients with various diseases, but failed to find any cases of porphyria Nevertheless, the Watson Schwartz test is simple to perform, and a mass survey of a population group would provide information concerning the prevalence of latent porphyria, which is at present unknown

Inheritance

Günther (1912) recognised that porphyria was an inborn error of metabolism, and Waldenström (1937) was able to follow the transmission of acute porphyria in nine families through two, and in one family three generations He considered that the families might be descended from a common ancestor and that the defect was inherited as a dominant character not linked to either sex Gates (1946) studied Waldenström's families and other evidence of inheritance in acute porphyria, and concluded that the dominance is often irregular, and that possibly two factors are involved

Although there have been many reports of cases of acute porphyria in England, especially in the past few years, the family history is frequently stated as negative, and we have been unable to trace any family tree in which dominance could be demonstrated Markovitz (1954) reviewed all case reports published in the English language between 1941 and 1953 These numbered 69, and a proven or suspected family history was reported in 11 instances, in 17 the family history was stated to be negative, and it is not mentioned in the remaining 41

Dean and Barnes (1955) studied the genealogies of thirteen porphyric families, all of Burgher stock with many intermarriages, and showed that porphyria in South Africa is inherited as a mendelian characteristic and is not sex-linked *In these families,* however, the disease appeared in the acute form, the chronic cutaneous form (the "cutanea tarda" type), or a symptomless porphyrinuria, and in many cases one clinical type changed into the other These workers regard acute porphyria and porphyria cutanea tarda as different manifestations of the same inherited disorder but in this country Calvert and Rimington (1953) showed that it is possible to distinguish them, for in porphyria cutanea tarda during remission the fæcal porphyrin level is raised

In the present study we have found more than 1 case of acute porphyria in each of two families (fig 1) Dominance was demonstrated in family 1, but in four other affected families we have been unable to trace any inheritance of the defect

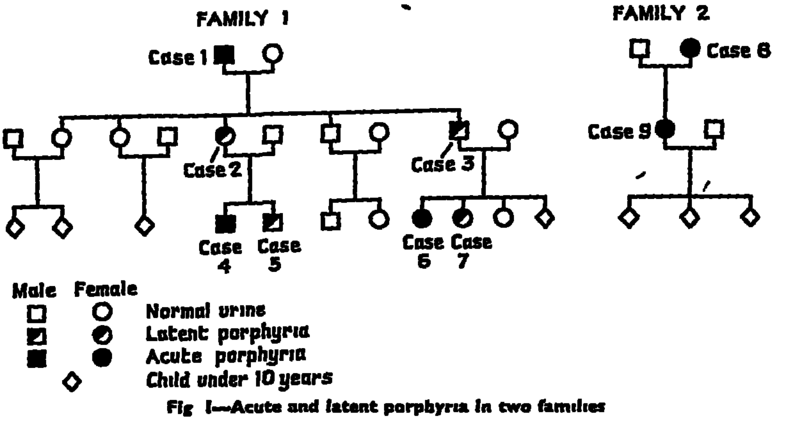

Fig 1—Acute and latent porphyria in two families

TRICUSPID VALVOTOMY

ARTHUR HOLLMAN
M D Lond , M R C P
RESEARCH ASSISTANT, CARDIAC DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON

DISEASE of the tricuspid valve is found in 22–36% of cases of rheumatic heart disease that come to necropsy but is severe in only 9–14% (Cooke and White 1941, Garvin 1943, Smith and Levine 1942), and severe tricuspid stenosis is found clinically in 3·3% of cases of mitral stenosis (Wood 1954)

Tight tricuspid stenosis can give rise to serious disability, with limitation of exercise tolerance by fatigue and angina, and in these circumstances relief of the stenosis is clearly desirable Tricuspid valvotomy has in fact been done in 18 published cases It follows from the known low incidence of severe tricuspid stenosis that this operation is likely to be done relatively infrequently

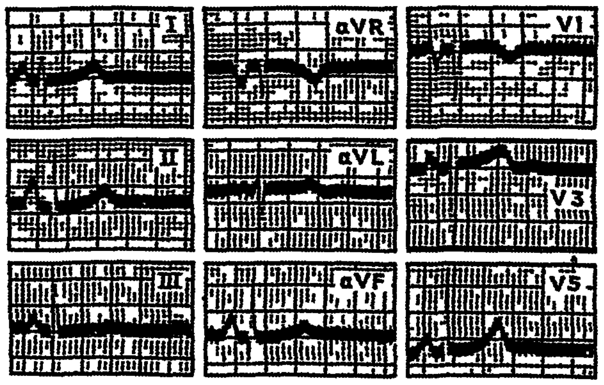

Fig 1—Electrocardiogram showing P pulmonale (II), P mitrale (V3), deep Q (aVF), and normal ventricular balance

I report here a case in which mitral and tricuspid valvotomy was done, review the published cases of tricuspid valvotomy, and discuss the problems that arise in relation to the operation

Case-report

A married woman, aged 24, complained of dyspnœa on exertion and of fatigue for five years, angina for four years, and ankle swelling for three years These symptoms had progressively worsened until she could not walk more than 100 yards Everyday activities fatigued her considerably and were accomplished only by a great effort There had been no hæmoptyses, emboli, paroxysmal dyspnœa, or rhythm change She had had doubtful rheumatic fever at the age of 5 years Her father had died from a coronary occlusion and her mother from kidney trouble

Physical Examination—She was well nourished, with no cyanosis or mitral facies The jugular venous pulse showed a dominant *a* wave 6 cm above the sternal angle The arterial pulse was of small volume, the blood-pressure was 130/70 mm Hg, and the hands were cool The apex beat was of normal quality, and there was no parasternal lift At the apex there were a loud presystolic murmur and a loud first sound, no systolic murmur, a soft opening snap, and a fairly long, low-pitched diastolic murmur of moderate intensity At the left 4th space the signs were very similar, except that with inspiration the presystolic and diastolic murmurs became much louder and longer An early blowing diastolic murmur was heard at the left 3rd and right 2nd spaces, and an opening snap too at the latter area The second heart sound was normal

RESULTS OF CARDIAC CATHETERISATION BEFORE AND AFTER MITRAL AND TRICUSPID VALVOTOMIES

—	Rt atrm	Rt vent	Pulm art	P C V	Cardiac output (litres per min)	A V O$_2$ diff	Tricuspid gradient		Mitral Rv/V
							Systole	Diastole	
Before	11/5(6)	24/0	24/10(14)	15/6(11)	3·2	6·12	10	4	0·9
After	9/2(5)	21/0	20/7 (12)	12/8(9)	4·0	5·00	6	2	1·38

Pressures in mm Hg Mean pressures in parentheses

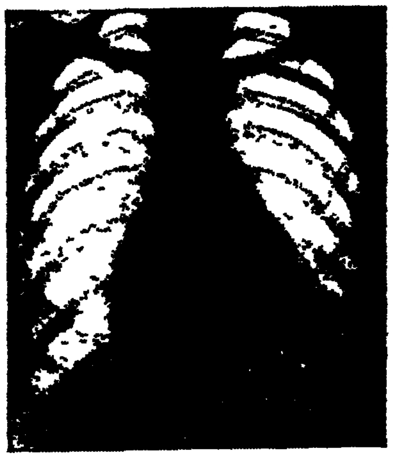

Fig 2—Radiograph showing considerably dilated right atrium

Investigations—Electrocardiography showed a 4 mm P pulmonale in lead II and a moderate P mitrale in V_3, with a normal ventricular balance There was a deep Q in aVF (fig 1) Radiography showed considerable cardiac enlargement (cardiothoracic ratio 65%) with well marked enlargement of the right atrium and moderate enlargement of the left atrium (fig 2) No valvular calcification was seen Cardiac catheterisation (see table) revealed a tricuspid gradient of 10 mm Hg in atrial systole and 4 mm Hg in diastole (fig 3) The *a* wave in the right atrium measured 11 mm Hg The pulmonary capillary venous (P C V) pressure of 11 mm Hg in the presence of a low cardiac output of 3·19 litres a minute suggested tight mitral stenosis, as did the Rv/V of 0·9 (Owen and Wood 1954) Pulmonary stenosis was absent

Diagnosis—The clinical diagnosis was mitral stenosis, tricuspid stenosis, and aortic incompetence The mitral stenosis was considered clinically to be fairly severe on the basis of a long diastolic murmur and a moderate P mitrale

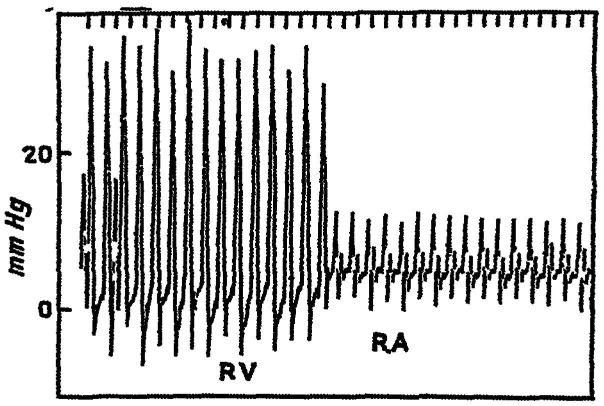

Fig 3—Cardiac catheterisation withdrawal tracing from right ventricle to right atrium showing tricuspid diastolic pressure gradient of 4 mm Hg (time in seconds)

The evidence for tricuspid stenosis was the large *a* wave in the absence of any signs of a high pulmonary arteriolar resistance, and the tricuspid diastolic murmurs Both lesions were confirmed at cardiac catheterisation and shown to be severe It was decided to undertake mitral valvotomy and, if this afforded no relief of symptoms, to proceed with tricuspid valvotomy at a later date

Mitral Valvotomy—Tight mitral stenosis was found, the valve orifice being 1 cm long, there was no incompetence It was necessary to cut both commissures, and each was split by about 1 cm thus producing moderate enlargement of the orifice Slight mitral incompetence was produced A striking feature, contrasting strongly with all other cases of mitral stenosis operated on here, was the normal size of the pulmonary artery Since the stenosis was severe, this was considered to provide good evidence, as did the absence of an opening snap over the valve at operation, that the pulmonary flow was greatly limited by the tricuspid stenosis acute porphyria After ingesting the drug she had an attack for the first time

The sulphonamide group of drugs and alcohol have also been incriminated, but the evidence against these substances is less strong than in the case of the barbiturates

The borderline between remission and relapse in acute porphyria appears to be very easily shifted, although too little is known of the factors responsible for the change in either direction

During the present study, case 9 had five attacks of acute porphyria in four years and case 4 had four attacks in two years Both patients were cooperative and intelligent, and we were able to obtain a most detailed history of the onset of the attacks, special attention being paid to any unusual physical or mental stress or any dietetic abnormalities during the fortnight preceding the attack In each case, and in each attack, the clinical manifestations were similar

The patient was in good health, carrying out the normal duties of a housewife or a factory worker The first symptom was colicky pain in the lower abdomen, which increased in intensity and often became continuous and lasted for several days The patient became constipated, but this did not precede the onset of abdominal pain by more than one day, or at most two The patients noticed that their urine became darker than usual and they became extremely apprehensive, both patients had neurological complications during previous attacks

On examination the patient's temperature was slightly raised but not above 100°F The pulse rate was increased by about 20 beats per minute, and both systolic and diastolic blood pressures were raised by about 20 mm Hg There was tenderness on superficial and deep palpation of the abdomen but no rigidity or rebound tenderness Nevertheless, these signs may easily be confused with those caused by an inflamed appendix lying in the retrocæcal position, and case 4 was operated upon at another hospital although the surgeon knew that he had porphyria

Investigations —The urine was either dark when passed or became so on standing, and contained porphobilinogen and porphyrins The serum-bilirubin level was sometimes slightly raised (1 5–3 0 mg per 100 ml), but other liver function tests gave normal results, and the rise in the serum bilirubin level remains unexplained The attacks passed off in a few days and the patients recovered rapidly Both of them have become more pigmented during the past two years, and hirsuties has developed in case 9

We are unable to suggest any precipitating cause for the recurrent attacks of acute porphyria in these 2 patients They had received no drugs, and there was no history of physical or mental stress, or of minor infections before the attacks No unusual food or drink had been taken and there was no excessive sexual indulgence No treatment was given, and we are equally ignorant of the factors which caused the attacks to subside

Rôle of Barbiturates in Acute Porphyria

In the past few years Rimington and his colleagues have made great advances in our understanding of the rôle of barbiturates in porphyrin metabolism (Goldberg and Rimington 1955)

Goldberg (1954) showed that various barbiturate hypnotics, especially those containing allyl groups, induced porphyric changes in the rabbit He also pointed out that barbiturates can inhibit some of the oxidative processes of brain tissue (Quastel and Wheatley 1933) Goldberg suggested that in addition to the possibility of a direct effect of a barbiturate drug on porphyrin metabolism, the hypnotic activity may aggravate the upset in brain and nerve metabolism described in acute porphyria by Denny Brown and Sciarra (1945)

Many reports emphasise the deterioration in the condition of patients with acute porphyria after the administration of barbiturate drugs (Prunty 1946, Jorgensen and With 1947) On the other hand, Turner (1938) and Discombe and D'Silva (1945) failed to note any relation between barbiturates and acute porphyria

All our patients were given barbiturates during one or more attacks of acute porphyria, and the complications that followed are recorded in the table It will be seen that the effect of giving barbiturate drugs during an attack of acute porphyria is unpredictable

Cases 8, 12, and 13 received barbiturates but recovered from attacks without any complications In case 4 paralysis of both arms developed after administration of gr 3 of quinalbarbitone, although in a previous attack the patient had received 0 5 g of thiopentone for a laparotomy and made an uneventful recovery Case 6 had three attacks of acute porphyria, during each of which she received barbiturates There were no complications on the first two occasions, but on the third very large doses of barbitone sodium and phenobarbitone were given at a mental hospital and she became completely paralysed in all limbs On the other hand, case 8 had received similar treatment, also in a mental hospital, and she did not have any paralysis

These data are insufficient to provide any conclusions as to the harmful effects of slow-acting, as distinct from long acting, barbiturates, or concerning those containing an allyl group, which according to Goldberg (1954) produced the greatest rise of porphyrin in rabbits' urine

In addition to our own cases, we studied many reports of other patients suffering from acute porphyria with neurological complications, and we were struck by the fact that all the patients had received some form of barbiturate medication—although in some cases paralysis of muscles was not noted until ten days after the barbiturate had been given (e g, case 4) Because cases of latent porphyria can have acute abdominal symptoms without having received any barbiturate drug (as in the later attacks in case 4 and in case 9), we suggest that the rôle of barbiturates in acute porphyria may be related more to neurological complications than to the precipitation of an acute attack

Pregnancy

Waldenström (1937) reported that 2 of his patients had died from acute porphyria during pregnancy, and he suggested that the hypnotic and other drugs given during this time might have been responsible He also thought that pregnancy itself might have precipitated an attack of acute porphyria, and Watson (1952) said that this might happen after a confinement On the other hand, Freedman et al (1952) reported that a patient with acute porphyria had improved during and after pregnancy

One of our patients was pregnant when acute porphyria was first diagnosed (case 11) and 2 others became pregnant during the course of the investigation (cases 9 and 7)

Case 11 —A married woman, aged 21, was admitted to a surgical ward with a history of abdominal pain, vomiting, and constipation for five days She had had a normal period three weeks previously, and the surgeon who examined her thought that she had a twisted ovarian cyst A laparotomy was performed under thiopentone anæsthesia, but no abnormality was found, a recently ruptured ovarian follicle was seen The abdominal pain persisted and she was treated with gr 2 of phenobarbitone daily On the day after operation the ward sister noticed that she was passing dark urine, but the significance of this was not appreciated, and it was not until she became paralysed in both legs on the twelfth day after operation that her urine was found to contain large quantities of porphobilinogen She died from respiratory paralysis a week later, an early fœtus was found in the uterus at necropsy

This patient had had no previous attacks of abdominal pain, nor any symptoms suggesting acute porphyria The urine of 6 of her relatives was tested for porphobilinogen, but none was found She had received no drugs before the onset of the pain, and we concluded that conception had played some part in the precipitation of the attack of acute porphyria

Case 9 —This patient had had two attacks of acute porphyria (with paralysis of her arms on the second occasion) when she told us that she was very anxious to have a third

Bailey (1955) points out that subvalvular fusion is much less common in the tricuspid than in the mitral valve, so this cause of difficulty, found with mitral valvotomy, should be absent from tricuspid valvotomy

In the 4 cases where details were given each of the three commissures was divided with equal frequency in 2, two commissures were divided, and in 2 one commissure was divided. In the present case the valve split naturally along the posteroseptal commissure, and in the other cases particular commissures were deliberately incised Bailey (1955) states that division of the anteroseptal commissure is to be avoided because it weakens the tricuspid valve "baffle" and is therefore likely to cause incompetence

A significant degree of enlargement was produced in all the published cases, the final valve orifice admitting $1^1/_2$-2 fingers or measuring 3 0-3 5 cm long The tricuspid-pressure gradient was measured before and after operation by cardiac catheterisation in 3 cases including the present one, and it was reduced by 1 3, and 6 mm Hg

Tricuspid incompetence is often found in tricuspid-valve surgery Anatomical study of diseased tricuspid valves led me to think that incompetence was likely to be a usual accompaniment of stenosis and to be found more frequently than with mitral stenosis, even when the tricuspid stenosis was tight (Hollman 1956) Incompetence was absent in only 2 of the 8 surgical cases in which this point was specifically mentioned After valvotomy moderate incompetence was produced in 1 case in which it had been previously absent but where incompetence was already present it was increased in only 1 case (the present one) I know, from personal communications on 2 unpublished cases that severe incompetence in 1 case fatal was produced at tricuspid valvotomy, it therefore seems important to avoid producing serious incompetence even if, as in the present case, this means only partial relief of stenosis

Associated Valve Disease—Severe mitral stenosis commonly coexists with tricuspid stenosis (Lewis 1946), and mitral valvotomy was done in all the published cases of tricuspid valvotomy except 1 (Krook et al 1955) When both valves are dealt with at one operation a sternum-splitting approach is advised (Bailey 1955) Severe tricuspid stenosis limits the mitral blood-flow and therefore decreases the symptoms and signs of mitral stenosis It may be difficult to judge the severity of the mitral lesion in these circumstances but cardiac catheterisation will prove the severity, and it is wise to assume that mitral stenosis, if present, is tight unless proved otherwise It is logical to do the mitral valvotomy first lest pulmonary œdema develop on relief of the tricuspid stenosis Disease of the aortic valve is often associated with tricuspid stenosis—in 35% of cases according to Osler and McCrae (1927) In none of the reported cases of tricuspid valvotomy, including the present one, was there serious aortic disease, but this may have been due to deliberate selection

Signs and Symptoms of Tricuspid Stenosis—Tricuspid stenosis is diagnosed clinically by observing a giant *a* wave in the jugular venous pulse in the absence of signs of a very high pulmonary arteriolar resistance (Gibson and Wood 1955) The diagnosis is confirmed by finding over the tricuspid area presystolic and diastolic murmurs which are intensified during inspiration, and according to Likoff (Bailey 1955), by turning the patient on to his right side, and occasionally by finding a tricuspid opening snap, as in the present case brought out by inspiration The symptoms of tricuspid stenosis are presumably due to limitation of cardiac output, with corresponding diminution in pulmonary venous congestion, fatigue and angina are thus prominent That these symptoms may be properly ascribed to tricuspid involvement is well shown in the present case where mitral valvotomy relieved the dyspnœa, leaving angina as the dominant complaint, which in its turn was relieved by tricuspid valvotomy

Summary

The case is described of a woman aged 24, with mitral and tricuspid stenosis, the dominant symptom of the tricuspid stenosis was angina pectoris Tricuspid and mitral valvotomy was successfully undertaken and partial relief of the tricuspid stenosis gave considerable symptomatic benefit

Among 18 reported cases of tricuspid valvotomy there were no deaths

Tricuspid incompetence is commonly associated with stenosis even when this is tight, and it is important to avoid producing serious incompetence at operation For this reason only a limited valvotomy may be possible

It is a pleasure to thank, for their encouragement and advice, Dr Kenneth E Harris under whose care the patient was, and Prof R S Pilcher who performed the valvotomies

TREATMENT OF HAY-FEVER WITH HYDROCORTISONE SNUFF

H Herxheimer M.D Frankfurt L R C P E
Monica McAllen M.D Lond, M.R C P

SENIOR HOSPITAL MEDICAL OFFICERS, UNIVERSITY COLLEGE HOSPITAL, LONDON

It is well known that hydrocortisone, in contrast to cortisone, will relieve certain disorders of the skin when applied locally It has also been used locally in chronic allergic rhinitis with some success by several workers Tuft (1954) used a hydrocortisone suspension combined with two vasoconstrictor substances acting as nasal decongestants, Rohen (1955) and Burger and Shaffer (1955) used a pure hydrocortisone suspension, and Foulds et al (1955) used hydrocortisone powder as a snuff

We present here the results obtained by treating 24 cases of pollen hay-fever with hydrocortisone acetate in the form of a fine powder applied locally to the nasal mucosa

Method

The patients, 10 females and 14 males aged 14-35 were chosen because of the severity of their symptoms and their lack of response to previous treatment, including treatment with anti-histamine substances to the limit of tolerance All gave a typical history of two years or more of continuous severe hay-fever during the summer months only All had a positive skin reaction to mixed grass pollens No case had been desensitised to pollen during the previous twelve months

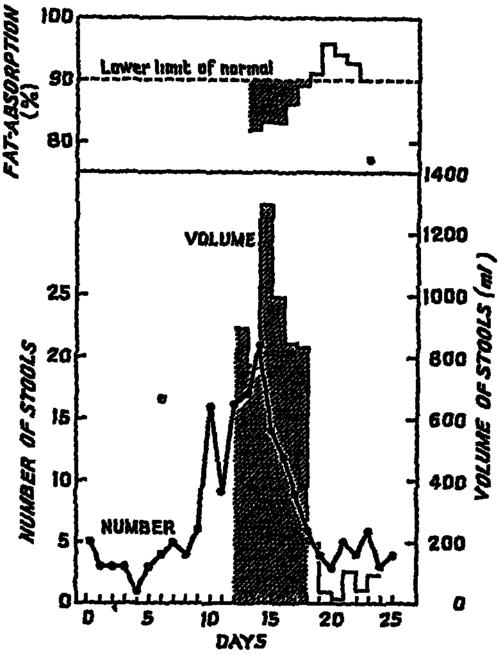

Fig 1—Fat-absorption and number and volume of stools (three-day means) of case 1 on a diet containing 50 g of fat daily hatched area, period in which phenolphthalein was detected in fæces

were any dysenteric organisms isolated A full course of antiamœbic treatment was given, the diagnosis being ulcerative colitis following amœbic dysentery Attacks of diarrhœa continued after his discharge from hospital, and, during an attack while he was visiting Birmingham, he was admitted to the Queen Elizabeth Hospital under the care of Prof T L Hardy

On examination there was no obvious wasting, and no abnormal physical signs were detected in the alimentary system Rectal examination was normal Sigmoidoscopy showed slight reddening of the mucosa, but the appearance was considered to be within normal limits, and no granularity or ulceration was noted up to a distance of 15 cm The patient appeared very concerned about his condition, gave a long and detailed account of his illness, and was obviously introspective

Laboratory Investigations—His stools were brown and semi formed or fluid, and microscopy showed them to contain an excess of fatty acid crystals but no pus or blood A barium meal ('Raybar') was normal, and a barium enema showed no ulcerative colitis or other colonic lesion A glucose tolerance test and chylomicrograph showed somewhat low rises in blood-sugar level and chylomicron counts respectively but were within the normal ranges A blood count was normal During a fat-balance test on a controlled daily intake of 50 g of fat the patient had an acute attack of profuse watery diarrhœa similar to those he had had in the past In the most acute phase twenty stools a day were passed, associated with an excessive fæcal volume Fat absorption during the early part of the attack was defective Details of the number of stools, fæcal volume, and fat absorption are shown in fig 1 At the height of the diarrhœa it was noticed that the addition of alkali to a fæcal aliquot turned it pink, and spectrophotometry of an alkaline filtered aqueous fæcal extract showed the absorption spectrum of phenolphthalein The disappearance of the pink colour on the addition of concentrated sodium hydroxide confirmed the identification as phenolphthalein When phenolphthalein had been found in the stool on four or five consecutive days, the patient was asked if he were taking laxatives This he denied, and a search of his possessions revealed none Within two days of this questioning, however, the attack of diarrhœa ended abruptly, an alkaline extract of his fæces was no longer pink, and his fat absorption became normal

Psychological investigation subsequently showed an intelligent patient, with great emotional tension and a background of incompatibility in marriage Moreover the question of attributability of his disability to Army service had been raised on several occasions In spite of this psychological background, the attack of diarrhœa observed in hospital was considered to be caused by the patient's taking phenolphthalein

Case 2—A married woman, aged 41, complained of attacks of diarrhœa and fæcal incontinence ever since anterior and posterior colporrhaphy had been done nine months earlier for stress incontinence of urine Two attacks had developed during convalescence and further attacks later with increasing frequency and diarrhœa had been almost constantly present before her admission to hospital She passed up to eight loose stools in the day time and often two at night, and she had been incontinent both by day and by night Her stools were very watery and contained mucus but no blood She appeared to give a good factual account of her disability and was regarded as a good and cooperative witness She said she was inclined to worry about small things in her home life, she had had some "spells of dizziness and sickness," but there seemed nothing abnormal in her previous history to explain her condition. She had seen a doctor only once during the nine months in which the diarrhœa appeared to have been a constant feature of her daily life

On examination no abnormality was detected apart from some pallor

Investigations—Sigmoidoscopy showed normal mucosa up to a distance of 25 cm A barium meal showed mild flocculation of the barium in the small intestine in the two hour and three hour films, and the cæcum was small and spastic Stomach, duodenum, and terminal ileum were normal A barium enema showed a normal colonic outline, but the colon was irritable, and the patient evacuated its contents on to the X-ray table A blood count showed a mild hypochromic normocytic anæmia, which subsequently responded to iron therapy Stools passed in hospital were loose and brown and were passed once or twice daily except on the first two days, when she passed five daily The fæcal fat was measured daily, with the patient on ordinary ward diet, by a modification of the method of van de Kamer et al (1949) The amount of fat excreted was within normal limits During the process of estimation it was noted that the alkaline fæcal emulsion was pink on ten days The urine passed in twenty four hours was collected on five days, and on only one of these days did the addition of alkali turn it pink The pigment was extracted from the fæces and urine and identified as phenolphthalein (see below) After phenolphthalein had been seen in the stool for about seven days, the patient was asked if she had been taking laxatives At first she denied taking any, but subsequently she admitted that she had taken two doses of a laxative since admission to hospital After questioning, her diarrhœa ceased, her stools became formed, and phenolphthalein disappeared from her stools

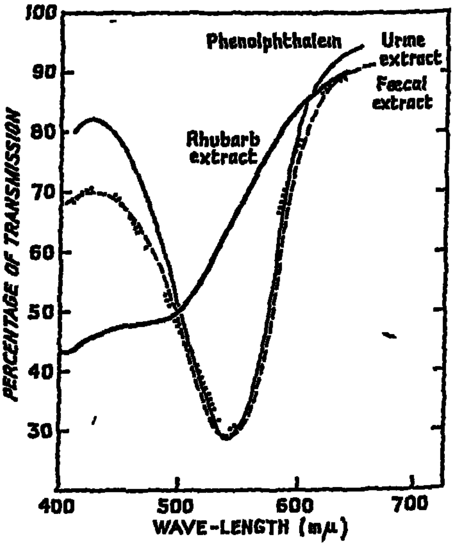

Fig 2—Absorption curves relevant to case 2

Extraction and Identification of Pigment

The pigment was identified in aqueous alkaline solution spectrophotometrically In case 2 it was extracted from was withdrawn, but all the patients who continued to take it throughout the whole season remained free, or almost free, from symptoms It is remarkable that 8 patients remained free from symptoms in spite of the withdrawal of treatment, and in spite of the fact that the season had only just started or was at its height A similar observation was made by Schiller and Lowell (1953) They gave oral cortisone 100 mg daily to 51 patients for four days This achieved complete or satisfactory relief in 42 patients, of whom 20 relapsed within a week The remainder were free from symptoms for the rest of the season It seems possible that in these cases and in ours a spontaneous partial desensitisation took place under the influence of these drugs Such desensitisation has been demonstrated experimentally under the cover of systemic cortisone (Herxheimer 1954) When some of our patients relapsed after a long interval of having no hydrocortisone, the time of their relapse did not coincide with any particular high atmospheric pollen count Possibly they had exposed themselves accidentally so heavily that the allergen broke through the protection given by a moderate degree of desensitisation In all these cases freedom from symptoms could be restored at once by resumption of the treatment

It would have been desirable to give a placebo powder during the withdrawal This would have shown us how many placebo reactors, if any, were in our series It is, however, unlikely that our very high proportion of successes could have been produced by psychological factors Moreover our patients had all had very severe hay-fever for several or many years and were very sceptical of this new treatment after the lack of success of previous efforts to relieve their symptoms The number of placebo reactors in our series can therefore be expected to be small We have been unable to observe a control series, because our supply of suitable patients with severe and uncontrollable hay-fever was limited and we did not wish to reduce our small series further

The method of treatment described here has one great advantage over desensitisation therapy in that it is safe Hydrocortisone powder in a dose of 15 mg daily applied locally to the nose for a maximum of eight weeks could not have any harmful effect even if most of it is absorbed.

Hay-fever, in severe cases, gives rise to much discomfort and disability, and any simple and safe method of treating it is welcomed by patients The subjects of this trial have been full of enthusiasm for the method, many of them stating that this was the first summer for many years they had been able to enjoy. Our experience in this small series indicates that the method is worthy of a wider trial during the next pollen season

Summary

In 23 of 24 patients with severe hay-fever who were given 15 mg of hydrocortisone snuff daily, complete control of symptoms was achieved during the first two weeks' treatment

In 17 of the 19 cases which could be followed up for the whole season satisfactory control of symptoms was achieved throughout

Of the 19 patients followed up 8 discontinued the hydrocortisone within three weeks and did not relapse thereafter

We are indebted to Messrs Upjohn of England for the supply of hydrocortisone powder and powder inhalers, and to Miss P McInroy for technical and other assistance

Artificial respiration by intermittent positive pressure (I P P.R) through a cuffed tracheotomy tube was introduced by Lassen and Ibsen (Lassen 1953) for treating respiratory insufficiency in poliomyelitis This way of giving artificial respiration has proved, in competent hands, the method of choice when the throat as well as the muscles of respiration is paralysed Thus I P P R has proved invaluable in combined bulbar and spinal poliomyelitis and in conditions such as polyneuritis and tetanus (during curarisation)

Various machines have been devised to provide a respiration pump for this purpose The apparatus described here has been developed from the Radcliffe respiration pump, type A, devised by Russell and Schuster (1953) As in the original pump, the positive-pressure wave is effected by the free pressure of a weight on bellows This has proved the best method we know of, for it removes all need for safety blow-off valves and gives a square wave form which provides the maximum of ventilation in the shortest time, and so imposes the minimum of strain on the circulation (Spalding and Young 1955) Further the visible movement enables the nurse in charge to recognise any abnormality in the speed at which the bellows falls

The original pump has been greatly improved by the manufacturers (Messrs H G East & Co) and has proved in practice a reliable machine capable of operating continuously for many months with very little maintenance The use of a Sturmey-Archer bicycle gear-box provides a wide range of speeds at small cost and very little noise The Stott flutter valve (Smith et al 1954) continues to operate well, even when water has condensed in it, and its snoring sound provides an audible check of the volume of expired air with each breath The expired air can be measured with a gas-meter as it emerges from the valve The whole apparatus, complete with humidifier (Marshall and Spalding 1953) and gas-meter, is shown in fig 1 The apparatus incorporates both a 230 volt A C and a 12-volt D C motor, which provide both for continuous use in hospital and for battery operation in the case of transport by road or air

Radcliffe Positive-negative Pressure Respiration Pump

The clinical results obtained by pumps of the type shown in fig 1 cannot easily be bettered (Smith and Spalding 1955), but some physiologists argue that a negative-pressure phase is desirable in expiration to facilitate the venous return to the right heart This has therefore been incorporated in the newest design, which is therefore called the Radcliffe positive-negative pressure respiration pump (figs 2–4) Cam-operated valves have also been introduced as being more reliable than pressure-operated valves The negative-pressure phase like the positive-pressure phase, is gravity-operated and designed to provide negative pressure from 0 to –10 cm water Other features are as follows

Alternative Motors—The apparatus incorporates both a 230 V A C and a 12-V D C motor The latter is convenient for travelling or in case of prolonged electrical failure

Medical Societies

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE 56th general meeting of the association was held at Cheltenham on April 5–7 There follow brief reports of some of the papers read at the meeting

The Rose-Waaler Test

Dr C L **GREENBURY**, Dr A G S **HILL**, Dr R **SPALDING SMITH**, and Dr M S **GOOD** had had over two years' experience with a modification of the Rose-Waaler test in a series of 700 patients, including 249 with rheumatoid arthritis The test was positive in 90% of all cases of rheumatoid arthritis, and in 93 5% of those with positive X ray findings A few cases of rheumatoid arthritis were negative early in the disease, but for the most part even the earliest cases gave good positive results There was no relation between activity, judged either clinically, by erythrocyte sedimentation rate, or by C reactive protein, and a positive test

Most of the tests were done in duplicate, using saline and 2 5% sheep serum as diluents for the test sera When sheep serum was used as diluent, titres were 2–16 times higher than with saline, and a few sera were positive in serum but negative in saline Sera producing agglutination of sensitised cells in a dilution of 1 16 or higher were taken to be positive, providing that heterophile antibody was present in minimal quantity or had previously been absorbed

It was found, in common with other workers, that serum in "collagen disease" also gave positive results Two further groups of patients were found to give positive results an at present ill defined group of patients attending skin clinics, and patients with diffuse pulmonary fibrosis, finger clubbing, and arthralgia, but no arthritis It was concluded that the Rose Waaler test, at least in the modification described, was a most useful and accurate aid to diagnosis

Tubeless Gastric Analysis

Dr **JOHN HARKNESS** recalled that Segal et al [1] had recommended an azure A/cation exchange resin compound in which the quininium of the present tubeless gastric analysis is replaced by a dye which eventually colours the urine This new compound still had the disadvantages of interference by *drugs and food*, and by the need for an injection of histamine to verify achlorhydria Dr Harkness proposed that a more reliable test was to estimate the overnight urinary excretion of quinine after an oral dose of 500 mg of quinine carbonate suspended in weak alcohol or water Food and drugs did not affect the result Although histamine was not given, it was claimed that this technique could detect the false achlorhydrias missed by the standard intubation alcohol histamine fractional test meal A satisfactory test could be carried out by a patient in his own home Achlorhydrics excreted 0–100 μg quinine in eight hours (further experience might increase the upper limit slightly), patients with free hydrochloric acid in the gastric juice excreted 320–30,000 μg in eight hours

Platelet 5-hydroxytryptamine in Blood Disorders

Dr R M **HARDISTY** and Dr R S **STACEY** had conducted an investigation to determine whether the incidence of purpuric manifestations in various blood disorders was related either to the concentration of 5 hydroxytryptamine (5 H T) in the platelets or to the total 5 H T content of whole blood The platelet 5 H T concentration was estimated, and whole blood 5 H T determined, in 83 patients with various disorders of the blood and reticulo endothelial system, including leukæmias, polycythæmia vera, lymphomas, pernicious anæmia, and simple iron deficiency anæmia, and in 15 non hæmatological patients [2] Low mean platelet 5 H T concentrations were found in a high proportion of cases of all the hæmatological disorders, and these often resulted in low whole blood 5 H T Experiments on the absorption of 5 H T by platelets in vitro suggested that these low platelet 5 H T concentrations were attributable to a defect of the platelets themselves The mean platelet 5 H T concentration in these cases was unrelated both to the blood platelet count and to the incidence of abnormal bleeding All but 2 of the patients with purpuric manifestations had both thrombocytopenia and a whole blood 5 H T below normal limits, but the incidence of bleeding was less critically related to the whole blood 5 H T than to the platelet count Dr Hardisty and Dr Stacey concluded that the bleeding of thrombocytopenia cannot be attributed solely to 5 H T deficiency, and that there are no grounds for supposing that a low platelet or whole blood 5 H T concentration, in the absence of thrombocytopenia, may be a cause of abnormal bleeding

Streptococci in a Maternity Unit

Dr J D **ALLAN GRAY** described the spread of group A hæmolytic streptococci among the staff and patients of a maternity unit It began among the pupil midwives with a succession of sore throats which did not yield to sulphonamides, penicillin, holidays, or tonsillectomy In spite of strenuous efforts, the organism spread among 55 of the staff and 57 of the patients The vast majority of both staff and patients showed either no evidence of infection or at most only a trivial illness 2 infants died 1 was thought to have had a cerebral injury and the other developed his fatal illness after his discharge from hospital While a combination of penicillin and streptomycin was required to eliminate the *streptococci from the staff, penicillin alone* was sufficient to eliminate them from the patients The striking difference between the staff and the patients in the difficulty with which the streptococci could be eradicated was eventually shown to be due to the presence of penicillinase-producing staphylococci in the noses of most of the staff

Sudden Death in Infants

Dr J L **EMERY** and Dr E M **CRAWLEY** had found that in a series of 50 sudden unexpected deaths in infants the history as obtained by the coroner was consistent in only 5 cases with histories obtained after the child had been buried The histories obtained by the coroner's officer were substantially inconsistent with both morbid anatomical findings and later histories in 33 cases The follow-up histories indicated some abnormality in all infants before death, and, in the majority, symptoms of over two days' duration The inadequate histories might be due to the shock of the tragedy to the mother, and to the fear produced by the police and the coroner's investigations The procedures connected with these "sudden deaths in infancy" apparently needed revision

Salivary Tumours

Dr J M **CAMERON** and Dr A **DICK** had studied 88 cases of salivary tumours with particular attention to the pleomorphic adenomata or the so called mixed tumours The parotid gland was the most frequent site, followed by the submandibular and sublingual glands in that order They first occurred between the third and fifth decades but no age was exempt, and their growth was extremely slow The tumour recurred in about 30%, whatever the treatment Dr Cameron and Dr Dick supported the view that the cartilage like material in many of these tumours was in fact not true cartilage but a myxo chondroid substance developed by degeneration from epithelium and stroma

Acute Renal Failure after Head Injury and Operation

Dr W H **TAYLOR** and Dr J V O **REID** defined acute renal failure as a blood urea level greater than 100 mg per 100 ml and a urinary urea level of less than 2 0 g per 100 ml Such failure developed after surgical operation or head injury in 25 patients who were examined post mortem In 15 there was histological evidence of acute tubular necrosis In of the *earliest cases, casts were seen to be* produced by hæmorrhages from capillaries into tubules These hæmorrhages might be important in the process of cast formation Of the 10 patients without acute tubular necrosis, 1 had normal kidneys and 9 showed only hydropic changes in the tubules In at least 4 of these cases the duration of acute renal failure exceeded forty eight hours, and this should have been long enough for acute tubular necrosis to have become manifest

Previously described clinical features of acute renal failure were not consistently present in either the tubular necrotic or non necrotic groups All 11 patients had oliguria (less than 300 ml of urine per day) The plasma/urine chloride ratio was greater than 4/1 in all patients except 3 with acute tubular microphone, oximeter, and CO_2-meter—can be added to the trolley if required

[2] Hardisty, R M Stacey R S *J Physiol* 1955, 130 711

The pump is illustrated in figs 2–4 with the side plates removed Fig 5 shows the type of wave form obtained with the pump on a patient, and it is seen that the square wave form appears in both the positive-pressure and the negative-pressure phases

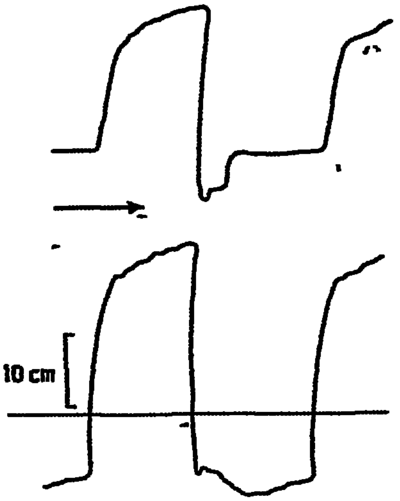

Fig 5—Wave forms obtained with positive-negative pressure pump with partial negative pressure and full negative pressure

Summary

Radcliffe respiration pumps have proved most successful in the treatment of combined respiratory and bulbar paralysis

A development of the original pump is described which includes a negative pressure phase

The design of this second type of pump has also been much improved by the manufacturers (Messrs H G East & Co, 37a, Oxford Road, Cowley, Oxford), to whom we are greatly indebted

DELAYED PROTHROMBIN ESTIMATION IN OUTPATIENT ANTICOAGULANT THERAPY

HAMISH WATSON
M B Edin, M R C P E
REGISTRAR IN CARDIOLOGY, MEDICAL PROFESSORIAL UNIT,
DUNDEE TEACHING HOSPITALS AND DEPARTMENT
OF MEDICINE, UNIVERSITY OF ST ANDREWS

PROLONGED anticoagulant therapy continued over months or years must of necessity be conducted on an outpatient basis Laboratory control is essential, and patients have to report at short intervals to a hospital with laboratory facilities for accurate prothrombin-time estimations and where the medical staff is skilled and experienced in the control of such treatment This has proved difficult where patients are either fully employed or cannot travel easily, and has led to loss of work and frequent use of the ambulance service Further, the maintenance of anticoagulant therapy is restricted to patients living where these facilities exist

Freshly withdrawn samples of venous blood are requested by laboratories for the one stage prothrombin test, and this, so far as can be ascertained, is common practice It is generally stated that the specimen deteriorates fairly rapidly, and Quick (1951), describing the test, states that, though the estimation should be made within 30 minutes in research studies, up to 4 hours' storage is permissible for routine clinical purposes

Since the necessity for rapid estimation appeared to be a major factor in the problem outlined above, it was decided to put it to the test by making a pilot study of prothrombin-times estimated 24 hours after withdrawal of the samples of blood This work was done in 1953 as part of a larger investigation, and the present report is prompted by the imminence of large scale clinical trials of prolonged anticoagulant therapy

It should be emphasised that the prothrombin-time estimations were not made as a research study but were made each morning in the laboratory with large batches in the usual routine way Certain precautions were taken, however, to ensure that the identity of the specimens was unknown to the technician making the estimations

Method and Results

The one stage prothrombin test was used with fresh human brain as the source of thromboplastin A fresh thromboplastin solution was prepared and a control specimen estimated each morning The samples of blood were obtained by clean venepuncture, 4 5 ml of venous blood being run into a glass tube containing 0 5 ml of 1 34% sodium-oxalate solution and carefully mixed On reaching the laboratory the whole specimen was spun for 10 minutes at 2500 r p m, and 0 1 ml of the plasma thus obtained was used for the estimation For the purpose of the investigation enough blood was taken at each venepuncture to obtain three specimens

(1) The first was labelled by the house physician and sent for estimation in the normal way with many others from the ward or outpatient clinic It was the specimen used to control the patient s daily dose of coumarin drug

(2) The second specimen was also sent for immediate estimation under another name

(3) The third was carefully wrapped and sent through the post addressed to the sender When it returned to the department 24 hours later it was sent for estimation with that day s specimens under a different name

As a further check the first two specimens were on several occasions retrieved after estimation, relabelled with different names, and posted in a similar way for estimation the following day The technician could not

* Where the control times differ, the error has been corrected to the first control time in simple proportion This is permissible since in the therapeutic range the curve of prothrombin activity is virtually linear

International Pharmacopœia, however, is in its infancy in the years ahead its virility will be revealed in its lists of additions and deletions

The bulk of the text is devoted to the 217 monographs Appendices, which form a supplement to those included in volume I, occupy about a third of the book They range over conventional chemical methods, biological assay, and tables of constants There is a schedule of "usual and maximal doses for most drugs," and another showing "usual daily doses for children" These are useful but they do not compensate for the omission of doses from the monographs The dosage tables also suffer because they are incomplete The *International Pharmacopœia* breaks new ground by its inclusion of a section on solutions of cardiolipin and lethicin for serological tests This "annex" was printed at the request of the subcommittee on serology and laboratory aspects of the Expert Committee on Venereal Infections and Treponematoses It creates a precedent of considerable importance to compilers of pharmacopœias

Neural Control of the Pituitary Gland

G W HARRIS, SC D, M D, F R S, Fitzmary professor of physiology, Institute of Psychiatry, Maudsley Hospital, London London Edward Arnold 1955 Pp 298 30*s*

IN this readable monograph Professor Harris describes the functioning of both the anterior and the posterior lobes of the pituitary gland As might be expected, his own work figures prominently in his account, and he admits in his preface to some bias in the presentation of material But he has produced a fascinating story which is sufficiently consistent to be readily followed and remembered yet does not belittle the uncertainties which still exist

The book begins with an account of the anatomy of the hypothalmus and hypophysis with special reference to their blood supply, and this is followed by a discussion of the mechanisms controlling secretion of the gonadotrophins, adrenocorticotrophin, and thyrotrophin In later chapters it reviews briefly but adequately the regulation of the anti diuretic factor and gives a clear and useful account of the hormonal aspects of parturition and lactation Neuro secretion receives brief but favourable mention, and the last chapter considers the hormonal influences which affect behaviour patterns in primates and other mammals

Professor Harris not only deals admirably with his special subject, but also touches informatively on many topics of general endocrinological interest

Diabetes

G F WALKER, M D, M R C P Pp 96 8*s* 6*d*

Cancer and Allied Diseases

RONALD W RAVEN, O B E, T D, F R C S Pp 121 8*s* 6*d*

Childbirth

W C W NIXON, F R C S, F R C O G Pp 106 8*s* 6*d*

London Duckworth 1955

THESE are three more volumes in the Modern Treatment series, intended for the general public Though not written for that purpose, they throw much light on current medical thought and practice They show an increasing desire to enlighten patients about normal and abnormal bodily happenings, about the medical approach to them, and about the modern medical armament—preventive and curative This rapport between doctors and patients is most desirable, but it is no easy thing to achieve To translate technical language (often, some would say, jargon) into lucid, unambiguous English is hard enough, to ensure that the translation will convey the true meaning to the lay reader is harder still, and to warn and advise without sowing fears or adding to the difficulties of the reader's own doctor is perhaps hardest of all The authors of these small books sometimes succeed in this difficult task but sometimes, perhaps inevitably, they fall short in one way or another

Diabetes contains much excellent practical advice, but the explanatory sections may not leave the reader much clearer about the nature of the disorder Unlike the other two, this book has no glossary or index

Cancer describes the nature of normal and malignant cell-multiplication and deals with radium, radiotherapy, and chemotherapy in some detail With the glossary's aid, the reader should be able to grasp what he is told In the clinical section, cancers of certain organs and regions have been chosen for relatively detailed description, including those of the pharynx, the liver, and the blood (leukæmia)—but not (rather surprisingly) tumours of the larynx, thyroid, prostate, or bladder, which usually have more specific early symptoms and are more amenable to treatment The discerning reader will find the book grim reading the absence of reliable warnings and the inefficacy of treatment for many sorts of malignant disease is all too clear Would it not have been better to concentrate on those few which an intelligent patient really can "catch in time" if he has the knowledge?

Childbirth has an admirable account of labour from the "labourer's" point of view, with effective photographs of models showing the nature of the birth process A chapter of "Any Questions?" includes a clear and comforting exposition of the rhesus situation Diet looms large in pregnancy food two hourly, no fried food, no salt at table, strict weight control, and no liquid paraffin With visits to clinics, systematic relaxing practice, and perhaps exercises, even the primigravida must have a busy time, and one imagines that the mother of one or two with a husband who fancies fried bacon would find the burden heavy

Sexual Precocity

HUGH JOLLY, M D, M R C P, consultant pædiatrician, Plymouth Clinical Area Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 276 50*s*

SOME years ago Dr Jolly started to study sexual precocity, hitherto those who wanted to know his conclusions have had to refer to an admirable but meagre paper in the *Proceedings of the Royal Society of Medicine*—that is, if they had not had the opportunity to read the thesis which won him the Raymond Horton Smith prize Now they can consult the full monograph, nicely produced in the United States and correspondingly priced

More than half the book is taken up by case-reports, many of them illustrated Sexual precocity in the physical sense, bewildering when first encountered, is seen to be resolvable into four groups constitutional (in which the child is normal in every other way, perhaps merely exemplifying how widely normal variation may extend), intracranial (hypothalamic-pituitary), gonadal, and adrenal In the first two there is premature puberty (which implies the production of ova or spermatozoa), in the others there is not To these may be added the cases produced by the administration (intentional or accidental) of stilbœstrol More of them may be seen now that potent endocrine preparations are so widely used

Until Dr Jolly's book is superseded by one written on the basis of investigations and theories yet unimagined, anyone thinking about a difficult case of sexual precocity can confidently turn to it for guidance

---

Poliomyelitis (2nd ed London Edward Arnold 1956 Pp 147 16*s*)—After four important years, full of developments bearing on the treatment and prevention of poliomyelitis, the second edition of Dr W Ritchie Russell's book will be widely welcomed as an up to date survey Some controversial matters, such as the value of exercising paretic muscles to the point of fatigue during the convalescent (rehabilitation) stage, are now better explained, especially in the light of the author's further work on muscle recovery Too timid physiotherapy is still condemned, and a timely plea is made for the wider adoption of methods of actual measurement of muscle strength, as by the spring balance This aspect of the subject, like many others, is well illustrated by photographs, line drawings, fatigue records, and other graphs Changes in the treatment of the acute stage, especially in respiratory and bulbar cases, are similarly well surveyed The method of intermittent positive pressure respiration introduced by the Danish school, now falls into its natural place, not as a first choice, but for patients for whom the tank respirator is inadequate Pathogenesis is dealt with in a graphic and satisfying way, particularly the changes in the motor nerve cells It would be hard to find anywhere an account of the clinical aspects of poliomyelitis so concise and yet so comprehensive me for examination at intervals determined by the ysician-in-charge Other visits, however, simply for e estimation of the prothrombin-time, could be obviated ith advantage to both patients and staff It is not uggested that the laboratory should take over their management by post, but that the number of visits to hospital could be reduced to a minimum Patients living locally may continue to report at times to suit their working hours, but, where they live far from the centre, blood could be withdrawn either by their own doctor or at a smaller hospital (where there are no laboratory facilities) and sent by post for estimation next day

It matters little whether whole blood or plasma is sent, so long as there is no contamination with surgical spirit Such contamination is a common cause of hæmolysis and interferes with the accuracy of the results

It is hoped that estimations of prothrombin time made up to 24 hours after withdrawal of the blood, without special precautions regarding storage in the interim, will reduce the very considerable labour and time expended in dealing with such patients, particularly where large numbers are involved

It may be that the results are less accurate if there is more than 24 hours' delay, and a further study is being made to discover the effects of increasing the interval between sampling and estimation

Summary

In the control of long-term anticoagulant therapy it makes little difference whether the samples of blood used for the estimation of the one stage prothrombin-time are fresh or 24 hours old

Possible therapeutic implications are discussed

This investigation was made in the Department of Cardiology, Edinburgh Royal Infirmary My thanks are due to Dr A Rae Gilchrist for his encouragement, the staff of the Clinical Laboratory, in particular Dr Elizabeth Gilchrist, without whose coöperation the investigation would have been impossible, and Prof I G W Hill for help and advice with the paper

CONTROL OF HYPOTENSION FOLLOWING REMOVAL OF AORTIC CLAMPS

J R Kenyon
B Sc, M B Glasg, F R C S, F R C S E
ASSISTANT TO THE SURGICAL UNIT

K E Cooper
M Sc, M B Lond
M.R.C GROUP FOR RESEARCH ON BODY TEMPERATURE REGULATION

ST. MARY'S HOSPITAL MEDICAL SCHOOL, LONDON

The operation of grafting segments of aorta, for aneurysm and thrombosis, carries a relatively high mortality, recorded by Rob (1955) as 17% in a series of 59 patients The mortality is greater when the aorta is clamped at a high level—that is, immediately below or above the renal vessels, in a consecutive series of 24 patients operated upon for aneurysms or thromboses there were 8 postoperative deaths, of which 6 occurred within the first forty-eight hours, of these latter, 3 occurred on the operating table following release of the aortic clamps, and 3 were due to coronary thrombosis occurring during the first or second postoperative day An aortogram illustrating the type of case on which these operations were performed is shown in fig 1

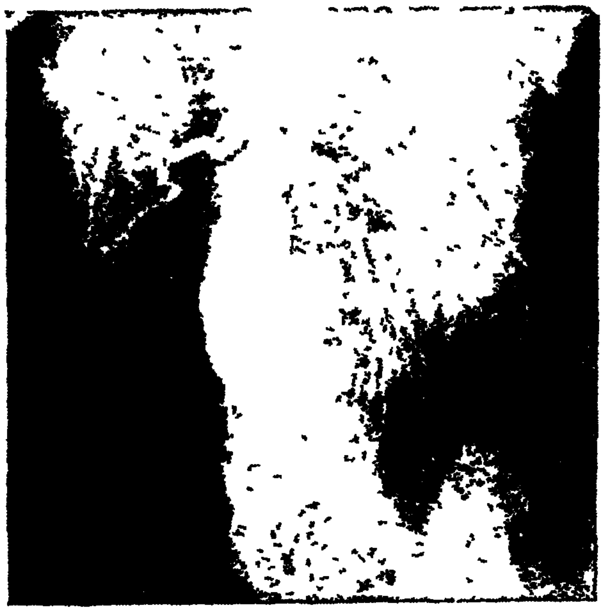

Fig 1—Aortogram showing large aortic aneurysm

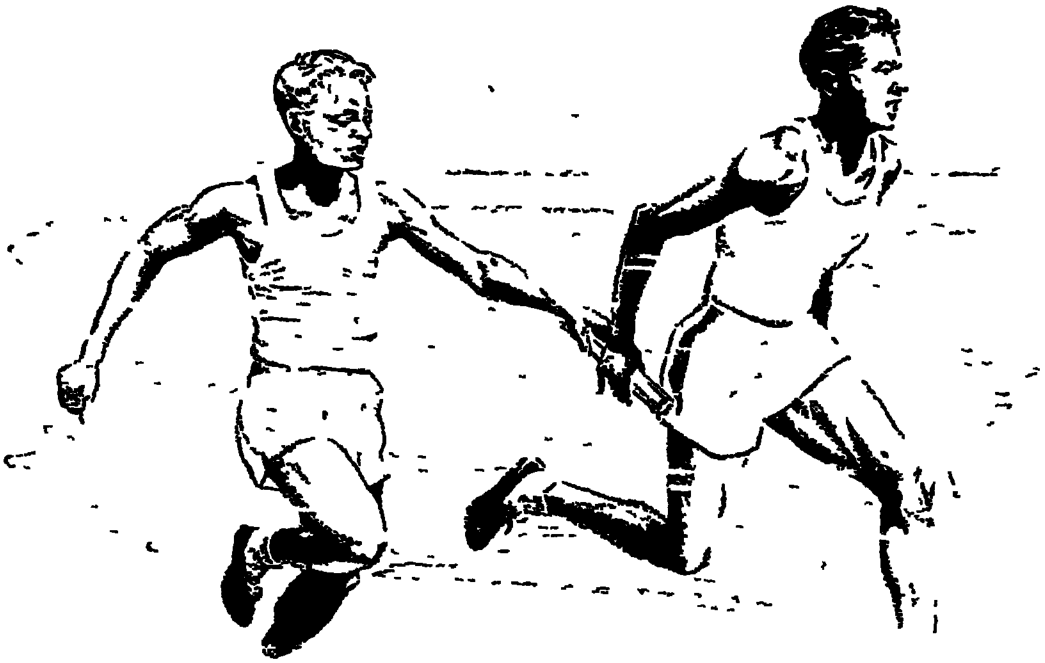
Release of the aortic clamp results in a dramatic fall of blood-pressure, which requires a rapid transfusion of blood and frequently an infusion of noradrenaline, before a satisfactory level is restored This period of hypotension may last for five to ten minutes, occasionally longer, and may result in a greatly diminished blood flow through the coronary arteries and the brain, to mention two organs whose blood-flow is greatly dependent on arterial pressure It seemed probable that the fall of blood-pressure was due to the return of blood to the previously ischæmic tissues and that it might be controlled by regulating this return This paper records preliminary results of an attempt to achieve such control

Calf Blood-flow

Calf blood-flows were recorded with a venous occlusion plethysmograph in 5 of the 24 patients, during the operation and the immediate postoperative period The plethysmograph was water-filled at 34°C, and in 2 patients operated on under hypothermia this was allowed to cool with the patient to 28°C The volume was recorded electrically (Cooper and Kerslake 1951) Ten-second inflow traces were recorded alternating with ten second periods of deflation of the collecting cuff The foot circulation was isolated with a cuff round the ankle inflated to 200 mm Hg during each three minute period of recording Fig 2 is representative of the results obtained, it shows hyperæmia in the calf on removal of the aortic clamp, coinciding with the period of hypotension The flow increases both when the patient is cooled and when he is not

Control of Hypotension

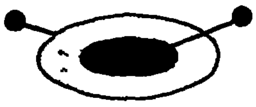
The hypotension may be partially controlled by gradual release of the aortic clamp, but in a grafting operation there is danger of thrombosis in the prosthesis if this phase is prolonged A simple apparatus has therefore been devised consisting of two arterial occlusion cuffs placed one on each thigh and connected to a mercury manometer and inflating mechanism, the valves being so arranged that the cuffs may be inflated or deflated independently The cuffs are placed as high on the thigh as possible before operation and, just before the aortic clamp is released, both are inflated to a pressure greater than the systolic blood-pressure—usually to 200 mm Hg After release of the aortic clamp the circulation is



Smooth take over

Bidormal provides the ideal answer to the management of insomnia It's two-phase action ensures steady sedation throughout the night

As the effect of the short-acting barbiturate pentobarbitone, contained in the outer shell of Bidormal, begins to fade, the action of the butobarbitone, contained in the inner core, takes over smoothly ensuring calm uninterrupted sleep for approximately eight hours



OUTER SHELL

BARROW HOSPITAL, BRISTOL, GLOS

In psychiatry, where there is little agreement on basic theory and most forms of treatment are empirical, there tends to develop a definite pattern of response to the introduction of any new therapeutic drug. Firstly, there are the preliminary reports of clinical impressions; these will determine what range of dosage and what frequency and duration of administration are likely to be most suitable; and if (as is usually the case) the drug appears to be of value, further investigations are indicated. Secondly come the controlled trials; these may show that the effect of the new drug is no better than that of a placebo, or they may show that it possesses an efficacy which cannot be explained simply in terms of interest and enthusiasm. In this latter case comparative trials must be made of the new drug against a standard preparation and it is here that the new treatment stands or falls for it must be shown either to possess some new therapeutic power or to be at least as efficacious as the standard treatment.

Such a pattern can be discerned in the use of reserpine, one of the alkaloids of *Rauwolfia serpentina*. First used in the treatment of hypertension, it was found to have a beneficial effect on the neurotic symptoms of hypertensive patients (Wilkins 1954). Reports followed on its use and efficacy in various mental disorders, especially in neurotic anxiety and tension. Controlled trials of reserpine in neurotic states have produced conflicting results (Davies and Shepherd 1955, Folkson and May 1955); but, even if it were established that neurotic patients improve more on reserpine than on placebo tablets, such improvement might be due simply to a non-specific sedative action of reserpine. This possibility can be tested by comparing the effect of reserpine with that of a barbiturate (*Lancet* 1955).

The aim of the present study was to make such a comparison. We used a dose of reserpine (2 mg. t.d.s.) which is rather higher than that generally used in the treatment of neurotic patients; we did this because published reports show a clear tendency towards increased dosage and a pilot study, in which patients were given this dosage for one or two weeks, did not reveal any disturbing side-effects.

Method

The value of the self-controlled and self-recorded clinical trial in low-grade morbidity has been pointed out by Hogben and Sim (1953), and the technique has been shown to give reliable results in neurotic patients (Hare 1955). Using this technique, the present investigation was planned to compare the effect of reserpine, amylobarbitone sodium, and an inert control substance on the general clinical state and certain specific symptoms in patients with neurotic anxiety.

Case material

The patients studied were all inpatients in a neurosis unit. None was hypertensive. A patient was admitted to the trial only if his major symptoms were anxiety and tension, if he was willing and intelligent enough to coöperate, and if he appeared to be a reliable witness. 42 patients began the trial but 9 did not complete it: 2 of these 9 discharged themselves against advice for reasons unconnected with the trial; 2 refused, during the first week, to continue, saying the tablets made them much worse (both were receiving control tablets); and in 5 cases it was considered advisable to interrupt the trial and to proceed with electroconvulsion therapy, although there was no evidence that the failure to improve or the worsening of the clinical state was associated with the administration of any particular drug.

33 patients (14 male, 19 female) completed the trial satisfactorily. In 4 of these (1 male, 3 female) the dose had to be halved after three days because of the complaint of excessive drowsiness; this happened in each case while the patient was receiving reserpine. We did not feel, however, that halving the dose seriously disturbed the course of the trial; so the records of these 4 patients have been included in the analysis of the results. The average age of the 33 patients was 42.5 years (range 23–64).

During the trial the patients received a hypnotic (mostly butobarbitone gr. 3) where this was indicated but no other treatment was given.

Administration of Drugs

Each of the three drugs was administered to each patient for a week, the whole trial lasting three consecutive weeks. Thus the patient received two capsules and two tablets three times daily; and although the capsules and tablets remained identical in appearance they contained, for one week each, either reserpine 6 mg. daily, amylobarbitone sodium gr. 6 daily, or an inert control substance. Until the conclusion of the trial the order in which the drugs were administered was known only to the dispenser. It was arranged that, for the 33 patients, each drug was given an equal number of times in each of the three weekly periods and that (so far as was possible) each drug was preceded by each of the other two drugs on an equal number of occasions. This distribution eliminates any bias due to a tendency for the patients to feel better at the end of the trial period * and any bias due to the possibility that the effect of a drug might persist from one week to the next.

Assessment

Daily record charts were prepared on which each patient rated:

(1) How he felt compared with the previous day—"better," "same," or "worse" (scored 0, 1, and 2 respectively).
(2) The degree to which he had been affected by certain symptoms (see table I)—"absent," "mild," "moderate," or "severe" (scored 0–3).
(3) The quality of his last night's sleep—"undisturbed," "slightly disturbed," or "restless" (scored 0–2).

In addition, he completed a record at the end of each week indicating:

(1) How he had felt on the whole during that week compared with the previous week—from "much improved" to "much worse" (scored 0–4).
(2) The quality of his sleep during the week (scored 0–2).
(3) New or particularly troublesome symptoms.

Objective checks on the validity of the patients' records were made in the following ways. The charge-before it will be possible to decide how variations in that ratio affect the prevalence of disease

---

* There was in fact a slight (statistically insignificant) tendency for the third week of the trial to be rated as better than the other two weeks.

SINCLAIR also postulates that the use of flour of low extraction-rate would significantly lower the effective content of the national diet in essential fatty acids and so predispose to atheroma and myocardial thrombosis and increase the prevalence of other diseases of civilisation, which he suggests may be attributable to relative deficiencies of these acids Here he is on very uncertain ground and can muster no direct experimental support He is right, however, in urging the need for more research on these problems, and in the present state of our ignorance it is surely rash to commit most of our population to consuming bread made from a flour about whose nutritive properties we know so little and have so many genuine doubts

Research into the origins of degenerative diseases of man is beset with difficulties Laboratory animals can be of only limited help, since in general they are much less susceptible than man It is also clear that noxious processes must persist for a long period before overt disease is manifest In this type of research the unit of time is the decade For the most part physiologists are still preoccupied by what happens in a few milliseconds, and even experimental pathologists like to get their results in a few weeks Established methods of medical research are thus not well suited to tackle the problems of the degenerative diseases The Cape Town workers are to be congratulated on the ingenuity with which they have devised an experiment which has established an important differential in the physiological effects of various dietary fats and oils They have, however, demonstrated effects lasting for only a few days clearly we should like to know that the vegetable and marine oils not only lower lipoprotein levels but can keep them low for long periods Their present findings, however, will be a stimulus to others to follow their clear lead in elucidating one of the gravest medical problems of industrial communities

A Merger?

HOSPITALS are very important and very impressive, but they ought not to dominate the medical scene, as they do now Whether people remain well and happy depends mainly on what happens to them, and is done for them, outside hospital, and we have repeatedly expressed our opinion that more of the resources of the National Health Service should be going into the kind of preventive and curative medicine that cannot be practised properly except where people live and work This view was put forcibly by Prof FRASER BROCKINGTON on Tuesday at the Blackpool meeting of the Royal Society for the Promotion of Health [1]

Last century, he said, all doctors in this country recognised that health is very largely a matter of environment, and as long ago as the 1830s disease was studied as a community problem But a hundred years later, in the 1930s, it had become customary to think of illness chiefly as a hospital episode Already the profession had retreated from its position of leadership in the challenge to environment, and "from the most enlightened of public-health pioneers, we have become the most backward, giving pride of place to the underdeveloped regions of the world To see public health in action, one must now go to Yugoslavia, Africa, Thailand, or to other and unmentionable places" One reason for this, paradoxically, is that public health has been so successful here, in eliminating the more obvious and dramatic plagues, that some people imagine it has nothing left to do, another may be that the appointment of medical officers of health has made the rest of the profession feel that public health is no longer their concern, but the principal single reason is the growth of interest in institutional care—which the National Health Service, so far from diminishing, has accentuated Under the N H S the hospitals are better organised, better staffed, and (taking it all in all) more efficiently and economically run than before, but BROCKINGTON holds that, in terms of public health, their nationalisation has been little short of disastrous, for they have been unnaturally elevated to a position of pre eminence, and are absorbing the best of the brains, and the lion's share of time and effort and money "The environment, upon whose inadequacies the whole of the apparatus of medicine is in reality constructed, has slowly receded into the background of our thoughts"

The primary need now, as BROCKINGTON and many others see it, is to shift the focus of medical care back to the community and to lessen the emphasis on hospitals "we want," he says, "a service for community health in terms of the family at home and at work, together with continuous study of disease and ill health within the community" And the obstacles, as he sees them, are not insuperable

> "Nowhere in the world has the concept of a family doctor been more firmly rooted than in Britain Nor have many countries been able to boast for so long a more complete cover of medical men trained in public health. Why should we not now bring these two great institutions together? We have the means wherewith to solve our difficulties in a merger of public health and general practice"

At present medical care for people in their homes is provided partly by the family doctor, working in contract with the local executive council, and partly *by district nurses, health visitors*, home helps, and *many other* medical and social workers employed by local authorities In BROCKINGTON's opinion this division of domiciliary services between two separate administrative machines is quite unrealistic "the general practitioner and the home nurse should work at least as closely together as the hospital consultant and the hospital nurse" As a professor of social medicine he evidently feels, too, that the family doctor's need of help from the health department is *at least equalled by* the health department's need of help from the family doctor General practitioners *should* be the *first* and *most* important agents in public health

> "Problems of care and aftercare, of the handicapped, of health education, the work of health promotion clinics, of immunisation and prevention of food-poisoning, of housing or such matters as the need to fluoridise the water-supplies, should concern them at every stage We cannot afford to leave the general practitioner working alongside, but not as part of, public health"

He believes that the right place in which, and from which, the practitioner should work is a health centre, which could give him the scientific and the social instruments for a modern approach to health, and also the advantage of team-work—not merely in the form some is shown by the fact that in 4 cases the dose had to be halved However, only one of the reserpine side effects (drowsiness) was really troublesome to the patients, and (as shown above) drowsiness often affected the patients receiving amylobarbitone sodium (also in rather high dosage) Yet, with amylobarbitone sodium, drowsiness did not stop the patients from recording that they felt improved This was not so with reserpine and at least 3 patients on reserpine specifically recorded that although they felt more drowsy and physically relaxed than before the trial began they felt no less anxious A similar " dissociated " response in a psychotic patient has been described by Tyndel (1955)

---

[1] Presidential address to the Section of Preventive Medicine

It is worth noting that the patients in this trial were almost entirely new cases, many of them being recently admitted to hospital for the first time They therefore received the benefit of full initial examination and assessment on admission, together with general reassurance There was no suggestion that their treatment was experimental, the patients simply being told that they were to receive a special three-week course of tablets and capsules The conditions of the trial were such that the findings are not invalidated by any improvement due to suggestion, since the conditions were the same during the administration of each of the drugs and the experimental method was based on a comparison between different periods and not on an absolute assessment In such circumstances, especially when the periods are relatively short, this type of trial acts as a combined treatment and research project, and it is very doubtful whether (in the interests of attaining scientific objectivity) the refinement of telling the patient that this is a new treatment, and that the physician does not know whether or not it will be helpful, is necessary or even advisable

The general conclusions to be drawn from this trial are that, for a week and in the dosages given, amylobarbitone sodium caused much improvement in the general condition and in the individual symptoms of the great majority of patients with anxiety neurosis, whereas the effect of reserpine was no better than that of an inert control substance This does not mean, of course, that in smaller doses or administered for longer periods, reserpine could not be beneficial in anxiety states, but it suggests the need for caution in accepting some of the enthusiastic eports of the efficacy of this drug, and it also suggests that, at least on a short-term basis, amylobarbitone sodium is of definite value

Summary

A comparison was made of the effects of reserpine 2 mg t d.s , amylobarbitone sodium gr 2 t d s , and an inert control substance on 33 patients with neurotic anxiety Each drug was administered for a week

A self-controlled self-recorded technique was used The reliability of the records was checked by internal evidence and by objective assessment

Compared with the control week, most patients recorded much alleviation of their anxiety symptoms when they eived amylobarbitone sodium, but there was no neral tendency to alleviation when they received serpine

We wish to thank Mr E F Wellington and Mrs J Sulcock, harmacists, for their assistance, and the nurses for their oöperation with the record charts Ciba Laboratories Ltd kindly supplied the reserpine (' Serpasil ') and the matched control tablets, and Eli Lilly Ltd the amylobarbitone sodium (' Sodium amytal ') and matched control capsules

ACUTE AND LATENT PORPHYRIA

S R F Whittaker
M A , M D Camb , F R C P
PHYSICIAN, WARWICK HOSPITAL

T P Whitehead
F R I C
BIOCHEMIST, SOUTH WARWICKSHIRE HOSPITAL GROUP LABORATORY

During the past five years we have encountered 8 cases of acute porphyria and discovered 4 cases of latent or symptomless porphyria in one family Since the area served by our hospitals is not a large one (population 150,000) we considered that acute porphyria is commoner than is generally realised We report the results of our study of the inheritance of the disorder, and discuss the factors that may precipitate an attack of acute porphyria

The clinical and biochemical classification of the porphyrias is controversial, but in this report the terms acute and latent porphyria are used to describe patients excreting excessive amounts of porphobilinogen in the urine without sensitivity of the skin

Material

The investigation is based on 6 women and 2 men whose ages ranged from 20 to 59 years (see accompanying table) Cases 4 and 6 are first cousins and case 8 is the mother of case 9 We have traced the family history of every patient and interviewed many relatives Specimens of urine were obtained from absent relatives and their medical history learned by correspondence with them and their practitioners

Examination of Urine

Colour

The urine of patients with acute porphyria, even during acute episodes, may be a normal colour, or it may be orange and dismissed as " concentrated " If the urine is left in daylight for a few hours, there is a definite alteration in colour, the urine becoming amber, particularly near the surface where it is in contact with air This simple test may be used as a preliminary test in a patient's home or at a cottage hospital where there are no laboratory facilities Urines from patients who have had blood-transfusions may also darken on standing, owing to the presence of other pigments , and therefore inspection of urine, even after allowing it to stand for some hours, is of limited value in the diagnosis of acute porphyria

In the laboratory, the darkening of the urine in cases of porphyria may be enhanced by heating it in a water-bath for ten minutes and then comparing the colour with that of an unheated control

Biochemical Tests for Porphobilinogen and Porphyrins

The urine excreted by all patients with acute porphyria (whether in the active or the latent phase of the disease) contains porphobilinogen This is the biochemical criterion necessary for diagnosis

Porphobilinogen is a colourless chromogen, but it can be identified by a simple chemical test using Ehrlich's aldehyde reagent, our technique being a slight modification of that proposed by Watson and Schwartz (1941)

To 2 ml of urine add 2 ml of Ehrlich's aldehyde reagent (0 7 g of *p* dimethylaminobenzaldehyde in 250 ml of 6 *N* hydrochloric acid) Mix and allow to stand for two minutes and then compare the colour with a mixture of 2 ml of urine and 2 ml of 6 *N* hydrochloric acid (this is a safeguard against artefacts caused by foodstuff colours excreted in the urine) Porphobilinogen gives a red colour which develops within twenty seconds, and urobilinogen gives a similar colour If a red colour is obtained, allow the mixture to stand for two to three minutes and then add 4 ml of chloroform and shake the test-tube , if the red colour remains in the aqueous layer the colour is due to porphobilinogen, but if it passes to the chloroform layer it is due to urobilinogen. Normal urines give no red colour

Gilchrist and **Tulloch** have treated 321 patients with a mortality of 18·1% and an incidence of thrombo-embolic episodes of 10·6% It is interesting to see that the mortality-rate has improved from 22·9% with the first dicoumarol treated series reported in 1950 to 14·4% in the phenylindanedione treated patients reported in 1954 With figures such as these, many people will wonder why anyone should oppose routine anticoagulant treatment for all patients, yet there is still much disagreement among cardiologists on this question

The reason, shortly, is that the mortality of coronary thrombosis depends largely on the extent of the initial lesion, the shock it causes, the medical history of the patient, and the occurrence of subsequent thrombo-embolic episodes **Russek** and **Zohman**[7] proposed an initial classification into "good risk" and "poor risk" cases, and they believed that anticoagulants should be given only to the poor risk group, comprising about 30% of patients In their experience the mortality-rate of untreated good-risk patients was only 2% and the incidence of thrombo-embolism less than 1% Since anticoagulant treatment itself is not without risk, they argued, there appeared to be no good reason for using it for so slight an improvement **Gilchrist** and **Tulloch** counter this view with several telling points They say that the doctor is faced with the individual patient and his family, and if 2 or 3 in 100 good risk patients can be saved by anticoagulant treatment when they would otherwise die, the slight risk is justified Moreover, it is hard to judge, six to twenty-four hours after the onset of an acute infarction, whether the patient is, in fact, a good or a poor risk, and they quote the experience of **Halpern** et al[8] who found it necessary, within forty-eight hours of the onset of the attack, to revise the grouping of about a third of their series of 117 patients But to delay a decision about anticoagulants for twenty-four or forty-eight hours is to deny a patient the benefits of early treatment **Halpern** et al therefore gave every patient anticoagulants, but they stopped treatment after forty-eight hours in all those who could then be regarded as good risks **Gilchrist** and **Tulloch** consider that this is too soon to stop treatment, and they recommend a minimum of ten days for the patient assessed as a good risk on the first day, should there be any unfavourable change, such as thrombo embolism, the course of treatment can then be extended by three weeks In the more severe cases they adhere to their previous recommendation of four weeks' treatment, extended if necessary by three weeks from the date of any subsequent thrombo embolism This programme means that *every* patient admitted to hospital is given anticoagulants, and this course can now be confidently adopted because the risk of therapeutically induced hæmorrhage has been so much reduced by present-day methods and drugs **Gilchrist** and **Tulloch**, using phenylindanedione, with efficient laboratory control, have had no serious hæmorrhagic complications in their last 120 patients If bleeding does occur, 10–50 mg of the oral vitamin K_1 emulsion will stop it

Gilchrist and **Tulloch** also discuss other possible effects of anticoagulant treatment They refer to the investigation of **Helen Payling Wright** and her co-workers[9] which showed that the rate of recanalisation of thrombosed arteries and veins is more rapid when the "prothrombin activity" of the blood is kept low Another point is that pulmonary infarcts are much less frequent in patients who have had anticoagulants, even though the patients ultimately die, thus, in 88 treated but fatal cases, there were 3 pulmonary infarcts, whereas in 160 control necropsies in untreated cases, pulmonary infarcts were found 27 times—a striking difference Prevention of pulmonary infarction is important because there is evidence, such as that provided by **Cole** et al,[10] that these incidents diminish the immediate and later chances of survival

The observations of **Gilchrist** and **Tulloch**, and all the arguments about anticoagulant treatment concern, almost exclusively, those patients with myocardial infarction who are admitted to hospital for treatment But not all patients with myocardial infarction are admitted to hospital, indeed, as **Morgan Jones**[11] puts it, "it is very doubtful whether any community will in the future be able to provide enough hospital beds for the treatment of all cases of coronary thrombosis, even if this were desirable" **Morgan Jones** reminds us that recovery is the rule if the patient is still alive when the doctor arrives If the patient is still alive, then the decision to recommend removal to hospital or treatment at home has to be made, and this decision often turns on whether or not he needs anticoagulants This brings us back once more to the assessment of prognosis, the decision between "good risk" and "poor risk" If the verdict is "good risk," then the relatively small advantage to be obtained from anticoagulants must be set against the risk of transport to hospital, if the assessment is "poor risk," then the patient should be got to hospital for anticoagulant treatment as soon as possible The responsibility for this decision rests usually with the consultant called to see the patient, and he may be fortified by **Morgan Jones**'s opinion that "there must be few serious conditions in which we can at onset separate off clinically as large a proportion of cases with so hopeful and encouraging a prognosis" Thus, **Morgan Jones** believes that good-risk patients can be treated at home without anticoagulants, and many cardiologists agree with him, but **Gilchrist** and **Tulloch** might not The alternative is to give anticoagulants to all good risk patients, comprising perhaps two thirds of the total number, and to do so, some means must be provided for practitioners to get prothrombin-time estimated on blood samples taken in the patient's home **Owren** and others have used long-term anticoagulant treatment for myocardial infarction[12], but in the domiciliary control of treatment from the start, blood samples must be collected at home and delivered to the laboratory and the result sent to the doctor as soon as possible In his article this week, Dr **Watson** records his inquiries into the possibilities of organising such a service, with results that, so far, seem encouraging

Case-reports

FAMILY I

CASE 1.—The grandfather of cases 4 and 6. This man died in 1940 at the age of 64, and unfortunately we lack proof that he had acute porphyria. Nevertheless, we have questioned his widow and his doctor, and think that the attacks of abdominal pain from which he suffered during the later years of his life (and for which no cause was found) were symptoms of acute porphyria. In addition, the records of his last illness describe extensive paralysis, which his widow asserts was very similar to that of her grand daughter. Members of his family state that his urine was sometimes very dark, but, as far as we can trace, it was never tested for porphyrins.

CASE 4.—A man, aged 20, and a first cousin of case 6. While he was serving in the R.A.F. his urine was found to contain moderate amounts of porphobilinogen. He was in good health and had not had abdominal pain or other symptoms suggesting acute porphyria. We therefore classified him as a case of latent porphyria and warned him of some of the inherent dangers of the disease. A few weeks later and shortly after the death of his cousin, he had a severe attack of abdominal pain associated with constipation and was admitted to a hospital in another part of the country as a case of suspected appendicitis. He informed the surgeon that he had porphyria, and the presence of porphobilinogen in his urine was confirmed, but laparotomy was performed under thiopentone anæsthesia and a healthy looking appendix was removed. He made an uneventful recovery from the operation, but was discharged from the R.A.F. on medical grounds. Three months later he had a further attack of severe abdominal pain. We had asked his practitioner not to give him any barbiturate drug, but he was attended on this occasion by a locum practitioner, who prescribed gr. 3 of quinalbarbitone (Seconal). On his admission to hospital the next day an increased amount of porphobilinogen was found in his urine, and his systolic and diastolic blood pressures were raised 20 mm. Hg above the usual levels. The attack of abdominal pain subsided in a few days, but ten days after the onset he complained of weakness of both arms and fairly extensive paralysis of the muscles of both shoulders and arms developed. He made a slow but good recovery during the next few months. During the past two years, this patient has had four further bouts of abdominal pain, but barbiturate drugs have not been prescribed and there have been no neurological complications. Porphobilinogen has been found in his urine whenever it has been tested, and the amount is greatly increased during an attack of abdominal pain.

CASE 6.—A married woman, aged 21, was admitted to hospital with complete paralysis of all limbs and some weakness of the intercostal muscles (fig. 2). Her urine was a port wine colour and the diagnosis of acute porphyria was confirmed by finding that the urine contained large quantities of porphobilinogen and porphyrins. During the previous three years the patient had had several attacks of abdominal pain for which two laparotomies were performed; on the first occasion a healthy looking appendix was removed, and on the second some adhesions were divided. The attacks of abdominal pain continued and she underwent a course of psychiatric treatment, including sedation with large doses of barbiturate drugs, after which weakness in both legs developed and she became completely paralysed in all limbs. Despite many forms of treatment the patient died five months after admission to hospital.

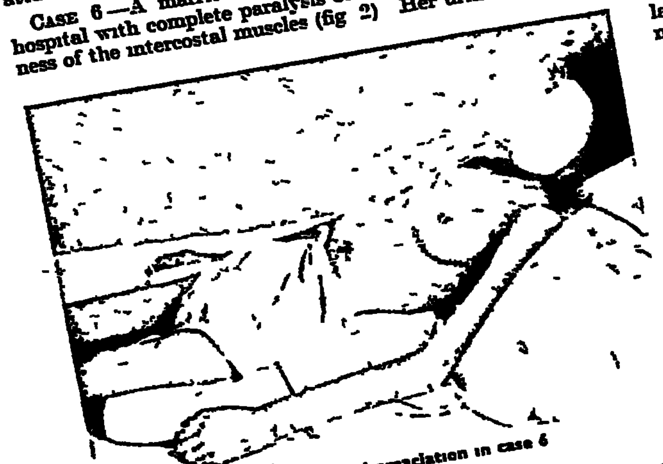

Fig. 2—Advanced emaciation in case 6.

Latent Cases

CASE 2.—The father of case 4, aged 45. He has no symptoms of acute porphyria, but his urine is often pink and contains a moderate amount of porphobilinogen.

CASE 3.—The mother of case 6, aged 43. She has no symptoms of acute porphyria; her urine is a normal colour but contains porphobilinogen.

CASE 5.—The brother of case 4, aged 19. He has no symptoms of acute porphyria; his urine is a normal colour but contains porphobilinogen.

CASE 7.—The sister of case 6, aged 20. She has no symptoms of acute porphyria. This patient has had two confinements without complications. Her urine is normal in colour but contains porphobilinogen.

FAMILY II

CASE 8.—The mother of case 9. She was treated for "plumbism" at the age of 35, and had a severe attack of abdominal pain for which a laparotomy was advised when she was 40. She refused operation and the pain subsided in a few days; she was free of attacks between the ages of 40 and 59 when they recurred several times a year. Despite numerous investigations, including radiography, no cause to account for the pain was found and she received psychiatric treatment, including electroconvulsive therapy, in mental hospitals. After her daughter had had an attack of acute porphyria, her urine was examined and found to contain much porphobilinogen. She died at the age of 64 from carcinoma of the stomach.

CASE 9.—A married woman, aged 36, was admitted to a surgical ward with lower abdominal pain and constipation. She was treated with enemas and given gr. ½ phenobarbitone twice daily and gr. 3 quinalbarbitone at night; the abdominal pain was relieved in a few days and she was discharged from hospital. She was readmitted to a medical ward fourteen days later with weakness of both arms; her urine was dark and contained porphobilinogen. During the next few days, paralysis of the extensor muscles of both wrists developed, and tests confirmed weakness of several other muscles in both arms and forearms. With active physiotherapy she eventually made a complete recovery but she has continued to pass varying amounts of porphobilinogen in the urine for the past four years. During this time she has had occasional attacks of abdominal pain and has twice been admitted to hospital for observation. No barbiturate drugs have been given and there have been no further paralytic episodes. She became pregnant last year and gave birth to a healthy girl; her urine contained moderate amounts of porphobilinogen during the confinement.

OTHER CASES

Our 4 other patients with acute porphyria (cases 10–13) came from different families; but although we investigated many relatives, including the parents of cases 10 and 12, we found among them no cases of latent porphyria.

CONCLUSIONS

The inheritance of the defect in acute porphyria as a dominant was confirmed in family I. In view of the negative family histories in many well authenticated cases, we think it possible that more than one factor is involved, or that affected members of the family excrete porphobilinogen intermittently or in such small amounts that it cannot be detected by the Watson-Schwartz test.

Precipitation and Features of Acute Attacks

Watson (1954) states that the mechanism by which the latent disease becomes manifest is unknown, and he suggests that there are various precipitating factors.

Günther (1912) referred to "toxic" porphyria because of the frequency with which acute attacks followed the ingestion of sulphonal and 'Trional'.

Waldenström (1937) administered a barbiturate to a woman who had never had an acute attack but whose sister had had study revealing the pitfalls which may trap those who make deductions from such an investigation (and also the means of avoiding them), they have proved that pulmonary tuberculosis is not related to the operation but rather to the standard of nutrition before operation The attack-rate is high in men 15% below their standard weight before partial gastrectomy, contrariwise, if the preoperative chest radiograph and weight are normal there is little to fear They point the moral every attempt should be made before partial gastrectomy to raise the weight of undernourished patients, since the chance of restoring nutrition after the stomach has gone is remote

CHILDREN NEED FAMILIES

FAMILY disruption undoubtedly contributes to juvenile delinquency Evidence of this has been impressively adduced by Bowlby,[1] in confirmation of earlier workers, including Healy and Bronner[2] and the Gluecks[3] Attention must therefore be given to the special problems of emotionally deprived children in any programme of delinquency prevention which claims to be comprehensive This is the theme of a second report,[4] recently published by the City of New York mayoral office, with the significant title Children Need Families The earlier New York report[5] dealt with broad preventive measures, the new one is concerned with the needs of children deprived of a normal home life It emphasises the fundamental principle, in the rehabilitation of these dependent and neglected children, that they should be cared for on the basis of a family group

The cornerstone of the New York programme is the provision of adequate numbers of suitably trained and professionally qualified social workers and counsellors, to augment existing child-welfare services within the city Their chief rôle would be to conduct intensive field work among families otherwise likely to break up in disharmony By providing close support and encouragement for emotionally inadequate, unstable, and often demoralised parents, the precarious family structure can be preserved and strengthened, thus reducing the load of emotionally deprived children for whom the community might otherwise become responsible This is sound preventive medicine it is also sound economics, since the cost of these expanded services is broadly balanced by the saving in keeping children out of trouble When the family has already broken down, or when breakdown proves inevitable, the aim is to reinstate the child, wherever possible and as soon as possible, within his own family, by a sustained effort directed towards the parents, or, failing that, to find him at least a secure substitute home with enlightened foster parents, or parents by adoption if that is appropriate This is, in essence, the reconstructive aspect of the programme It is good to see the increasing recognition of these principles, and the decline of the earlier policy of accommodating such children in homes and institutions where their healthy emotional development was often endangered by the starched and impersonal atmosphere As Mr Epstein's report puts it, "children well fed, well groomed and clothed, substantially sheltered (in these homes), may still be miserable children A chef in a stainless steel kitchen can hardly ladle mother love into the soup"

In this country, similar considerations are steadily gaining ground, as illustrated by the 7th report on the work of the Children's Department of the Home Office[6] In London, the health committee of the London County Council proposes to employ some 50 additional whole-time home helps, with the object of trying to keep together, at home, families whose children might otherwise have to be received into care, through illness or incapacity of the mother[7] A proportion of these home helps, after training, will also work with and teach housecraft to mothers who need help of this kind As in New York, the aim is to prevent family dissolution rather than cater for its aftermath

While applauding the expansion of these social services, we must temper our support with caution The help given by welfare workers to families in need of readjustment and rehabilitation, involves encroachment upon emotional conflicts and intimate personal problems which demand tact, technical training, and enlightened understanding for their satisfactory resolution It is of vital importance to ensure that the additional social workers to be recruited in this sphere have had the necessary training, and are imbued with a sense of responsibility that matches their rôle as home savers Children do need families, but they must be stable and emotionally intact ones

EKIRI

FOR a long time Japanese physicians and pathologists have been claiming that a form of acute infantile disease, *ekiri* (also known as *hayate* [typhoon] and as *kyusho* [acute illness]), though possessing many affinities with bacillary dysentery is not strictly speaking a shigellosis As most of the work has been carried out in Japan it has not attracted much attention in other parts of the world It has, however, aroused much local interest—so much so that a special study of it was made in the summer of 1947 by an American research team, and last April a symposium was held at Kyoto during the annual meeting of the Japanese Association for Infectious Diseases

A report from Japan[8] on the ætiology of *ekiri* from the clinical, pathological, bacteriological, and biochemical aspects leaves many questions unanswered The *ekiri* state, though acknowledged to be related to bacillary dysentery, resembles peripheral vascular failure due to anoxia in small children Deinbee Naito observes that the syndrome occurs only in Japanese infants, it is common among those aged 2–7, but no sucklings suffer from it The syndrome consists in disturbances of the central nervous and circulatory systems in combination with disorder of the intestinal tract It is thought to be due to some toxic product which acts mainly on the vascular system It is stipulated that the toxin is non bacterial—for instance, one of the toxic amines, which it is impossible to detect in the blood, though in the acute period there is a remarkable increase of blood ammonia (0 84 mg per 100 ml) Amine formation is presumably due to the intestinal flora, the majority of tyramine producing strains are *Escherichia coli* and *Aerobacter aerogenes* Sakamoto and Suzuki assert that the syndrome is not fulminating bacillary dysentery It is distinguished by intense circulatory disturbances Sakamoto has brought forward evidence that it is a typical shock manifestation in response to a food allergy, for which he holds *miso*, a kind of soybean, responsible

Despite the involved and often conflicting arguments it is difficult to escape from the suggestion that organisms of the dysentery groups are the chief factor In Japan bacillary dysentery is widespread and severe, the fatality rate in infants in the Kyoto Municipal Hospital, despite chemotherapy, is still over 10% Confusion may have arisen because of the difficulty of culturing the dysentery group from the necrotic mucosa, where these organisms are swamped by other bacilli child In consultation with Prof C H Gray we strongly advised her against such a course, but nevertheless she became pregnant a year later and was safely delivered of a baby girl with the aid of pethidine During pregnancy, she had two mild attacks of abdominal pain and passed moderate amounts of porphobilinogen in her urine, but the amount was not increased at delivery or during the puerperium.

CASE 7 —This patient, aged 20, is a case of latent porphyria belonging to family 1 She has had two normal confinements without an acute attack of porphyria developing, and she hopes to have more children. Apart from avoiding barbiturate drugs, no special precautions were taken during her pregnancies. The amount of porphobilinogen passed in the urine was not increased during her last confinement

Comments

The factors which cause a patient with latent porphyria to have an acute attack are unknown but many instances between the ages of 18 and 30 (when pregnancy is most likely) have been reported. Possibly the bad reputation which pregnancy has acquired as a precipitating cause of acute porphyria is in part due to the coincidence of the period of greatest fertility with the age-group which is most susceptible to acute porphyria

Mental Symptoms

It is well known that mental disturbance is a common accompaniment of acute porphyria, and Markovitz (1954) reported that mental changes were noted in over three-quarters of the 69 patients in his review In the present study, cases 6, 8, and 12 had spent periods in mental hospitals, and cases 4, 9, and 11 had psychological upsets during porphyric attacks Cases 6 and 11 died, but the other patients recovered and their mental state became normal as the attack subsided In addition, we observed no mental disturbances in 4 cases of latent porphyria (family 1), and we suggest that the so-called porphyric temperament is not a common feature of the disease The histories of many patients with acute porphyria is a lamentable tale of wrong diagnoses, unnecessary operations, and sedation or shock treatment, possibly these vicissitudes may have caused the " nervous constitution " mentioned in some reports This should not be confused with the mental symptoms that often accompany attacks of acute porphyria

Treatment

The efficacy of any treatment is notoriously difficult to assess in acute porphyria in which spontaneous remission and rapid improvement are common (Rimington and Goldberg 1954) During the past five years, we have treated ten attacks of acute porphyria in 7 patients with one or more of the following drugs neostigmine, potassium and calcium salts, corticotrophin, cortisone, 'Eucortone,' and large doses of vitamin B_{12} and other vitamins No beneficial effect was noted, and rational therapy must await a clearer understanding of the chemical pathology of the disease

On two occasions acute attacks were accompanied by a striking decrease in the serum sodium level (to 103 m eq per litre in case 12, and 118 m eq per litre in case 13) Both patients were considerably improved by infusions of normal saline, and we agree with Davies (1949) that careful control of the electrolyte balance is essential during acute attacks

When abdominal pain is severe or during a confinement we use pethidine, and paraldehyde is preferable to barbiturate drugs as a sedative for patients with mental symptoms although the pathogenesis of porphyria is at present unknown, barbiturate drugs should not be prescribed We treated 3 patients in artificial respirators, but they all died

Cases 4 and 9 survived an attack during which the muscles in the shoulders and arms were paralysed and we were agreeably surprised by the full recovery of function that they achieved with physiotherapy—and in a shorter time than is usual for a similar paralysis caused by poliomyelitis

Summary

In five years 8 cases of acute porphyria have been found in a population of 150,000

Inheritance by mendelian dominance has been demonstrated in one family

The precipitation of an acute attack and the influence of barbiturates and pregnancy are discussed

Mental disturbance is a common accompaniment of acute porphyria

We thank Prof C Rimington, F.R S, and Dr A Goldberg for their help and interest in this investigation, and Dr A I Cheyne for allowing us to study case 10

DIARRHŒA DUE TO PHENOLPHTHALEIN

THE exact diagnosis of many cases of chronic diarrhœa often remains in doubt, they may be labelled " colitis," nervous or lienteric diarrhœa, and so on Further elucidation of this ill-defined group will depend on more complete and accurate methods of investigation Routine use of fat-balance tests to assess the function of the small intestine has, for example, already shown that idiopathic steatorrhœa is the cause of many such cases (Cooke et al 1953) The technique for the fat-analysis of the stools that we now use is essentially that of van de Kamer et al (1949), by which the total fatty acids excreted are estimated daily The two following cases of diarrhœa due to phenolphthalein were discovered accidentally by this method Such a cause was quite unsuspected, and the diagnosis would otherwise have been missed

Case-reports

CASE 1 —A man, aged 30, complained of attacks of intermittent diarrhœa for nine years He said they had begun in 1943, when he started to pass frequent bloodstained stools after being captured in Germany while serving as a commando His weight fell during imprisonment from 12 st to 7 st in six months Although the diarrhœa improved it continued until his release in 1945 After treatment in a British hospital it gradually improved until 1951 Between October, 1950, and November, 1951, he had ten attacks of abdominal pain and vomiting with diarrhœa Investigation in another hospital in November, 1951, included sigmoidoscopy, which showed ulcers suggesting old amœbiasis No amœbæ were seen, nor authorities in order to have heroin back The A M A is still vigorously opposed to its return

In Germany, the heroin fatherland, it has not been used for a considerable number of years, it has practically disappeared from legal and illegal traffic alike For the time being the drug is suppressed by administrative means in anticipation of a prohibition by parliamentary Act The German Pharmacological Society and the Association of Chambers of Physicians have been consulted and have raised no objection

No better illustration of the change of opinion can be given than that of Switzerland At the 1931 conference the Swiss delegation declared that heroin was considered "indispensable for the treatment of certain diseases, in particular for certain cases of tuberculosis"[11] Twenty years later, however, Switzerland promulgated a new federal narcotic law in which the importation and manufacture of heroin, and trade in the drug, were prohibited[12] This time, as the Swiss Federal Council stated in its message, the medical profession accepted the complete prohibition of diacetylmorphine[13] Thus, although the same types of diseases have to be treated as twenty years ago, the medical profession can now do without heroin Not one voice against this regulation has been raised in the Swiss medical journals, nor, as far as I could see, in the daily press In the same message, the Swiss government said "It should not be forgotten that the problem is of primary importance from the social and health points of view, and that in taking the initiative of this decision, the country will fulfil a humanitarian task which is in keeping with its traditions" There was no addiction to heroin of any importance in Switzerland which would have required suppressive measures, and the decision may have meant some commercial disadvantage since orders from foreign countries for other pharmaceutical products may be lost when the export firms are unable to supply heroin as well This action by Switzerland therefore seems to me a particularly impressive example of international cooperation Several countries where heroin has been abolished, retain a small stock of heroin *for scientific purposes or for the use* of any doctor who feels that in a particular case its administration is indispensable

There are reasons to expect that at least one of the four countries which remain in favour of the use of heroin in medical practice will presently change its attitude

British Opinion

I have followed with attention the development of the "heroin case" in Great Britain within the last few years, and particularly what has been written in the medical journals during the last fifteen months

There is no doubt that, within the obvious limits set by public health, the doctor should be free to prescribe the drug of his choice this is one of the necessary and fundamental rights in the conscientious practice of medicine It is also clear that a drug which has been used for several decades to the satisfaction of many colleagues should not be abolished without the agreement of the medical profession On the other hand, we all have some conservative tendencies in the use of medicaments As has been mentioned, opinion has changed in Switzerland, and the same is true of Canada where it was formerly divided but where now (according to the Canadian delegate at the meeting of the Commission on Narcotic Drugs held in New York last spring) "the prohibition of heroin would not cause any difficulties in medical practice"[14]

When, on the recommendation of the British Pharmacopœia Commission,' the monograph on heroin was deleted from the 1953 edition of the *British Pharmacopœia*, there was in the medical press no relevant discussion When it became known in the House of Commons in February of last year that the Government intended to abolish the use of heroin from Jan 1, 1956 the voices raised in the important medical weeklies were much less numerous than might have been expected.

The discussion at the annual representative meeting of the British Medical Association last June[15] showed, if I understood it correctly, that there was some misunderstanding as to the reason for the proposed abolition of heroin, although Dr E A Gregg, the chairman of council, referred quite *correctly to the dreadful picture* of heroin addiction Similarly, in some of the letters to the medical press doubt has been expressed whether the disappearance of heroin from medical practice would help in the suppression of illicit traffic of that drug I am sure that it would do so, indirectly, for, as THE LANCET has said,[16] "the more countries that impose the ban the easier would be the task of those checking illicit traffic, for wherever the ban operates any heroin found is certainly illicit" But the World Health Organisation is not responsible for controlling the illicit traffic in drugs It is a medical body and the purpose of its proposal was and is simply to try to prevent the *creation of heroin addicts in medical practice*

The official figure of only 54 heroin addicts at present known in the United Kingdom is small—though it forms a fairly high proportion of the total of about 300 recognised drug addicts It is not, however, negligible if I am right in supposing that at any rate the great majority of the 54 developed their addiction through therapeutic administration of the drug Many of them, perhaps would never have become addicts if they had been given another, less dangerous, drug instead of heroin with its great euphoric potency

Reference has been made to "political pressure" from the World Health Organisation for the banning of heroin[17] As a retired medical officer of W H O, I can say that no such pressure was ever in question A resolution of the World Health Assembly, which is composed of delegates of the Member States, the overwhelming majority of whom are physicians or (if not) advised by physicians, cannot properly be characterised as "political pressure"

Alternative Drugs

What is quite clear from this correspondence is that some doctors still regard heroin as a most valuable drug for which there is no complete substitute[18] *One of them* writes[19] "It seems inescapable that many of the depreciatory remarks about heroin emanate from people who do not know its value, rather like the Russian gentleman who said whisky was not such a good drink as vodka because he had never tried it" For my part I should say just the opposite—namely, that many insist on the irreplaceability of heroin because knowledge of the alternatives is not yet widespread enough

In discussing the possibility of replacing heroin fully by less dangerous (though also addiction-producing) drugs, we have to consider both its antitussive and its analgesic action

Antitussive

Besides codeine and dionine, which are not always strong enough and can have undesirable side effects, hydrocodone (e g, 'Dicodid'), acetyldihydrocodeinone (e g, 'Acedicone'), and dihydrocodeine (e g, 'Paracodine') have been used for a long time Among the fæces and urine first with amyl alcohol and then redissolved in aqueous sodium hydroxide Phenolphthalein 65 mg given to another person was readily identified in the stool by the same procedure The extraction of rhubarb with amyl alcohol yielded solutions which became red when redissolved in sodium hydroxide, owing to chrysophanol (also present in senna), but the colour was different to the eye from that of phenolphthalein and its absorption-curve was different (fig 2)

Discussion

Though both patients denied taking laxatives at the material times, diarrhœa ceased abruptly after they had been questioned about this The disappearance of diarrhœa coincided with the disappearance of phenolphthalein from the stools There seemed therefore to be good reason to believe that the diarrhœa was due to the phenolphthalein, and that their word could not be accepted Although in both patients there was some psychopathic background malingering could not be ruled out

Most of the average dose (60–240 mg) of phenolphthalein is excreted in the fæces because phenolphthalein is rather insoluble (von Vamossy 1902), and some of the absorbed portion is excreted in the bile Phenolphthalein excreted in the urine is in the free form (after large doses only) and conjugated as sulphate and glycuronate, mainly the former, in which state it does not turn pink on the addition of alkali unless it is first liberated by hydrolysis by boiling with hydrochloric acid It may be excreted for several days in the conjugated form after a single dose (Fantus and Dyniewicz 1937) A simple confirmatory test would therefore seem to be examination of the urine for free and conjugated phenolphthalein

In the present cases diarrhœa was possibly initiated by either a single large dose or several smaller doses but the urinary investigations were too few to indicate the dosage

It is difficult to estimate how often this type of case occurs, but in a review of 1000 consecutive gastro-intestinal cases Soper (1938) found 177 habitual takers of purgatives containing phenolphthalein, 152 of these cases had been diagnosed as catarrhal colitis Soper noted that symptoms of colitis disappeared when the offending drug was withdrawn, but he did not state in how many this sequence of events was seen Ease of detection must vary with the purgative used. In the present cases detection was made simple by the readiness with which phenolphthalein appeared when the fat-balance was being estimated by the method of van de Kamer et al (1949)

The steatorrhœa seems worth recording Phenolphthalein effects purgation primarily by preventing the absorption of water from the large or the small intestine or both, it does this directly by stimulating the motor mechanism and indirectly by increasing the intestinal secretion and thus the bulk of the contents, to which the intestine responds by increased peristalsis (Fleig 1908, Ott and Scott 1908, Blick et al 1942) The presence of excess fat in the stool indicates that the small intestine is involved in the process The fat-absorption defect may thus be the result of an acute diarrhœa due to small-intestine hurry

Summary

Two cases of diarrhœa due to self-medication with phenolphthalein are described and the methods of detection outlined

Attention is drawn to the possible importance of self-induced diarrhœa as a clinical syndrome and a further cause of steatorrhœa

We wish to thank Prof T L Hardy and Dr C F Hawkins for permission to publish cases 1 and 2 respectively, Dr H G Sammons and Mr John Taylor for help with the analyses in case 1, and the United Birmingham Hospitals Endowment Research Fund, the Mackenzie Mackinnon Trust, and the Medical Research Council for financial assistance

Preliminary Communication

TREATMENT OF HYPOPHOSPHATASIA WITH CORTISONE

We have previously reported[1] certain metabolic abnormalities in a female infant with hypophosphatasia

The patient presented at the age of 5 months with markedly defective skeletal calcification, particularly in the metaphyseal regions The total serum calcium level was elevated, the inorganic phosphorus was normal, and the alkaline phosphatase activity was considerably below normal The patient has been under our observation for the past sixteen months, and until seven months ago the skeletal lesions were becoming more pronounced, though slow linear growth of the long bones was taking place

In June, 1955, we were led to postulate that a disturbance in adrenal cortical function was producing the skeletal lesions in this child In consequence we administered cortisone to suppress adrenal function The administration of 100 mg, and later 50 mg, of cortisone for a total period of two months did not alter the radiographic picture and produced toxic side effects However, a reduction in the serum-calcium level and an elevation of the serum-alkaline phosphatase activity to low normal values encouraged us to administer a somewhat lower dose of cortisone Within three weeks on 37 5 mg of oral cortisone daily, radiographic evidence of mineralisation appeared in the long bones at the zones of provisional calcification, and within the next seven weeks very considerable calcification took place in the metaphyseal, diaphyseal, and subperiosteal regions The bones were continuing to grow and their appearance was approaching normal During this second period of cortisone therapy the total serum-calcium and alkaline phosphatase levels again became normal

Schlesinger et al[2] have shown that spontaneous and sometimes rapid improvement can occur in hypophosphatasia, and for this reason we have withdrawn cortisone on three occasions In each instance the alkaline phosphatase activity fell to pre treatment levels within two weeks Moreover, during a two-month period without therapy we have observed a recurrence of defective calcification in the new matrix which was laid down at the growing ends of the long bones

From these findings we believe that cortisone produced a remission of many or all of the pathological features in our case of hypophosphatasia At present we do not know whether the beneficial effects of cortisone were mediated indirectly through suppression of abnormally functioning adrenal tissue or whether they were due to a direct pharmacological action on the disease process

conclusion that only about 10%—rarely up to 15%—of the served food went into the pig-bin.

Results

Tables I–V summarise briefly the results.

Calories

The energy value of the average intake (table I) compares favourably with the recommendations of the British Medical Association (1950): 2750 calories daily for men on light work and 2500 calories for women, with 80 and 73 g. of protein. Incidentally our figures are slightly lower than those cited in the last report of the Ministry of Food (1953). Thus the calorie intake of the patients appeared to be satisfactory, and their diet contained sufficient animal and total proteins.

TABLE I—AVERAGE DAILY INTAKE OF FOODS PER PATIENT *

Month (1951–52)	Calories	Protein (g.)	Fat (g.)	Carbohydrate (g.)
October	2930	77	105	430
November	2800	73	98	406
December	2725	71	94	398
January	2700	71	93	393
February	2850	73	102	408
March	2775	72	99	399
April	2800	70	102	390
May	2715	71	101	388
June	2965	87	104	420
July	2770	72	99	397
August	2825	84	98	401
September	2875	76	101	41[illegible]

* Calculated from all food delivered to the kitchen (after McCance and Widdowson 1946).

Hæmoglobin

The hæmoglobin estimations (table II), performed only as a sideline and always by the same experienced observer, show considerably lower values than those found by Olbrich (1947) for elderly people living in institutions (13.9 g. per 100 ml. for males and 13.2 g. per 100 ml. for females). It is perhaps pertinent to refer here to the many other causes of anæmia, such as chronic infection, occult bleeding due to peptic ulcer, colitis, and cirrhosis of the liver, which are so commonly found in patients with chronic ill health.

Prothrombin-time

A pilot survey of prothrombin time gave normal values (table III) (normal clotting time was standardised at 25 seconds).

Carotenoids and Vitamin A

As table IV shows, the level of blood carotenoids in our patients was less than half that of other patients from London, and the blood vitamin A level was similarly much lower. Incidentally in 1945 we found similar low carotenoid levels in a boys' institution (Moore and Leitner 1949). On the other hand when 50 Claybury patients chosen from those with the lowest carotenoid levels, were given daily a good helping of carrots or spinach (170 g.) their blood carotenoid level was trebled within forty-four days, and the blood vitamin A level rose even higher than that of controls (Leitner et al. 1954). This demonstrated clearly that in certain aspects the hospital diet was far less satisfactory than that of the general population.

TABLE II—HÆMOGLOBIN ESTIMATIONS*

Group	No. of patients	Age (yr.)		Hb	
		Range	Mean	%	g. per 100 ml.
Males	178	16–89	59.5	82.3	12.2
Females	136	21–92	62.2	72.4	10.72

* Evans photo-electric hæmoglobinometer calibrated 100% = 14.8 g. per 100 ml.

TABLE III—PROTHROMBIN-TIMES

Group	No. of patients	Mean age (yr.)	Mean prothrombin time (sec.)
Males	57	58.5	[illegible]
Females	19	61.4	[illegible]

Vitamin C

The vitamin-C status (table V) seems at first sight satisfactory. The gross average of the mean time necessary for saturation with ascorbic acid in our patients, from estimations throughout the year, was a little more than four and a half days. Only one similar investigation has been made in a mental hospital (Horwitt 1942) and in this the vitamin-C status was expressed as plasma ascorbic-acid levels. The comparison of results by these two methods is not easy (Prunty and Vass 1944), but our four and a half days' mean saturation time certainly does not compare unfavourably with the low plasma ascorbic acid levels obtained by Horwitt in the U.S.A.

The purpose of the saturation test is to show whether the ascorbic acid intake has been above or below some accepted standard of intake, and, if below, how much below (Harris 1943). We agree with Harris (1942) that in persons who are on the borderline of scurvy (or have scurvy) saturation usually takes seven to ten days.

In the Claybury patients the time needed for saturation varied widely, and this is consistent with the well known seasonal variations (Harris and Olliver 1943). More than 10% of all our patients became saturated only on the seventh day of loading or later. In most cases the delayed saturation was found between March and July. A similar delay was present in our patients during three successive years. In fact of 117 men and 122 women patients examined during the "spring periods," 24 and 18 respectively fell into this group, while the corresponding numbers in 118 men and 103 women patients between July and March ("autumn period") were 2 and 4 respectively. Most of these patients with delayed saturation had obvious clinical signs of the scorbutic state. Nearly all had follicular hyperkeratosis with or without perifollicular hæmorrhages over the gluteal area,

TABLE IV—BLOOD-LEVELS OF CAROTENOIDS, VITAMIN A, AND VITAMIN E *

—	Patients in Claybury Hospital				Control patients		
	No. of patients	Mean age (yr.)	Mean stay in hospital (yr.)	Mean values	No. of patients	Mean age (yr.)	Mean values
Carotenoids (I.U. per 100 ml.)	179	59	16.5 (range 2–52)	88	220	45	219
Vitamin A (I.U. per 100 ml.)	159	„	„	118	219	„	150
Vitamin E (mg. per 100 ml.)	175	„	„	1.15	64		1.31

TABLE V—ASCORBIC ACID SATURATION TESTS

Group	No. of patients	Mean age (yr.)	Mean body weight (lb.)	Mean stay in hospital (yr.) (range)	Mean saturation time (days)
Males	235	48.9	129.9	17.7 (2–44)	4.8
Females	22[illegible]	52.6	125.6	11.0 (2–5[illegible])	4.5

necrosis, so that unregulated tubular loss of chloride with a plasma/urine ratio of about 2/1 was not a characteristic feature The specific gravity of the urine was fixed between 1008 and 1014 in only about a quarter of the cases

Dr Taylor and Dr Reid concluded that after head injury and operation acute renal uræmic failure may be present in the absence of histological tubular necrosis, and that when there is tubular necrosis its characteristic clinical features may be absent, thus causing confusion in diagnosis

The "Buffy Coat" in Anæmia in Pregnancy

Dr H B **Goodall** described how microscopic examination of the "buffy coat" from the hæmatocrit had been applied to the investigation of anæmia in pregnancy By giving a remarkably true reflection of the type of erythropoiesis in the marrow, it had enabled the diagnosis of "pernicious anæmia of pregnancy" to be made even when the rest of the peripheral-blood picture was not characteristic During this investigation it was also found that erythrophagocytosis is not uncommon in the blood of pregnant, parturient, and puerperal patients The possibility that the ingested red cells were fœtal had in one case been confirmed by differential agglutination, but in other instances the phenomenon might merely indicate a hæmolytic process affecting the maternal erythrocytes

Pituitary Necrosis in Raised Intracranial Pressure

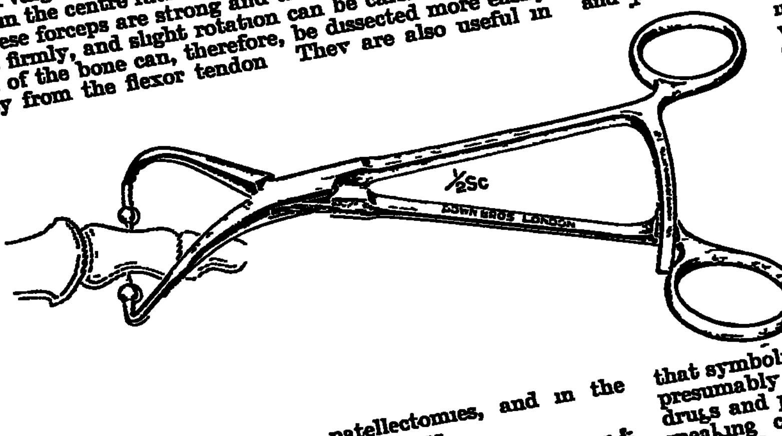
Dr Lionel **Wolman** said that among 270 patients dying with a tentorial pressure cone resulting from a unilateral space occupying lesion, 12 instances of recent necrosis of the anterior lobe of the pituitary were found The necrosis due to infarct ranged in extent from a small solitary area to as many as five discrete areas occupying most of the pars glandularis, but separated from each other and from the capsule by a zone of intact tissue The age of the infarcts, histologically assessed, could be correlated with the probable duration of tentorial coning The blood supply to the anterior lobe passing down the hypophyseal stalk was considered to be impaired by the distortion of the optic chiasma, hypothalamus, and infundibulum The mechanism which produced these infarcts seemed to be quite distinct, and Dr Wolman separated this group from postpartum necrosis of the pituitary and from various other causes

New Inventions

HALLUX FORCEPS

The forceps here portrayed are designed to hold the proximal end of the 1st phalanx in Keller's operation for hallux valgus (The diagram shows the forceps holding the bone in the centre rather than more proximally)

These forceps are strong and they grip the base of the bone firmly, and slight rotation can be carried out The base of the bone can, therefore, be dissected more easily away from the flexor tendon They are also useful in other procedures such as patellectomies, and in the operative treatment of certain fractures



The instrument is made by Messrs Down Bros and Mayer & Phelps, and I am indebted to Mr V G Carter of that firm for his help in their design and construction

Reviews of Books

Outline of Orthopædics

John Crawford **Adams**, M D , F R C S , consultant orthopædic surgeon St Mary's Hospital, London Edinburgh E & S Livingstone 1956 Pp 423 32*s* 6*d*

This is a book for students, and a very welcome one It aims to give "an easily read account of our present knowledge and thought on orthopædic surgery in the shortest possible compass consistent with accuracy, and without resorting to the style of a synopsis" Orthopædics is now so vast a subject that the success of such a book depends as much on the author's choice of what to leave out as of what to put in, and on the whole Mr Adams has done admirably

Nearly a third of the book is a general survey of orthopædic disorders, this is necessarily superficial, but it probably covers the irreducible minimum which the student must know The later chapters on specific regions contain very useful and orderly sections on history taking and physical examination, and throughout the book there is constant and admirable emphasis on the clinical side Some may wish to see more stress laid on the need always to have the other limb exposed for comparison The diagrams are clear and most of the radiographs are outstandingly good

The individual surgeon may find many points open to criticism, and he might reasonably say that some of the text particularly that dealing with the ætiology of certain conditions, is rather old fashioned—but perhaps this is good for the examinee If the student cannot feel with his hands that one trochanter is higher than the other, will the construction of Bryant's triangle really help him to decide the point? Some will be disappointed that there is so little indication of where manipulative methods of treatment may be helpful

On the whole, however, Mr Adams succeeds splendidly in his difficult task, and his book should be in steady demand by medical students

Pharmacopœia Internationalis 1955 Vol II

Geneva World Health Organisation Pp 350 35*s* Also published in French

The first volume of the first edition of the *International Pharmacopœia* was published three years ago, and it is gratifying to learn from the preface to volume II that its predecessor was given a good reception and is now in wide use The origins and scope of volume II are stated succinctly by the editorial committee

"The urgent need for the publication of volume I, which arose from the developing activities of the World Health Organization in co ordinating and unifying the health activities of its Member States, led to the omission from that volume of certain drugs concerning which rapid advances in knowledge and practice were being made Volume II supplies these omissions and deals with various forms of insulin, with tubocurarine chloride, and with the antibiotics chloramphenicol, chlortetracycline, dihydrostreptomycin, oxytetracycline, penicillin and streptomycin. Some synthetic chemical drugs of recent introduction to therapeutics are included and an attempt is made to complete the information given in volume I by including, in appropriate instances, monographs on compressed tablets, sterile injections, and tinctures"

The scope of the work is now comparable to that of the older national pharmacopœias Here and there, however, there are signs of compromise—which is perhaps as well in a work that symbolises international cooperation This attitude presumably explains the inclusion of a number of drugs and preparations which are in eclipse in English-speaking countries When, in 1955, monographs are published on bismuth subnitrate, bismuth salicylate, amidopyrine, aconite, sodium barbitone, and tincture of digitalis, some people may wonder whether national fashions have got the better of good judgment The suggested that the urge to have children was too strong ever to be suppressed, and that easy and effective birth control would simply enable a family or a population to cut its coat according to its cloth

A lively argument arose over the morality of "artificial" versus "natural" birth-control The panel agreed that birth-control should operate before, not after, conception, but disagreed on the permissible ways of preventing conception Mrs Stocks could not see the ethical difference between any methods of contraception once the motive of sexual intercourse with the deliberate intent of not having children was approved To restrict intercourse to the safe period with this intent seemed to her to be no different from mechanical or chemical contraception at the same or any other time, except that it was less effective, it was the motive behind the act that was the key to the ethical problem Lady Pakenha could not agree

Doctors were hardly mentioned The participants clearly held that the determination of national and individual policy on birth control was the province of biologists, economists, statesmen, and churchmen Mrs Stocks thought that *the doctors' job was to devise and* disseminate contraceptives

Symposia

THE NEUROHYPOPHYSIS

In Michael Foster's textbook of physiology of 1894 it is stated that nothing is known of the function of the posterior lobe of the pituitary gland By 1898 the gland was recognised to contain a vasopressor substance Three years later Magnus and Schafer described the diuretic action of extracts, and in 1906 Dale noted their oxytocic properties These facts were recalled by Sir Henry Dale in his opening address at the Colston Symposium on the Neurohypophysis, held in Bristol on April 9–12 The subsequent communications made it clear that the posterior lobe has not only three recognised functions—the control of water excretion by the kidney, of movements of the uterus during parturition, and of the ejection of milk as a result of suckling—but also almost certainly other just-glimpsed activities In fact the posterior lobe may be one of the conductors of the endocrine orchestra of which the anterior lobe is the first violin

The posterior lobe is part of a system which in vertebrates is old in the evolutionary sense, and which also has its homologues in many invertebrates It is probably *part of a neurosecretory system*—i e, *the neurones* manufacture active substances which are normally liberated from the ends of the axons In invertebrates such as worms, crustacea, and insects a number of such systems are known, the secretions are stored in gland-like structures and are concerned with growth, metamorphosis, and reproduction amongst other functions (B Hanstrom) In higher vertebrates the active substances are made in the supraoptic and paraventricular cells of the hypothalamus and are stored in the posterior lobe of the pituitary There is evidence that the histological appearance of this hypothalamic/posterior-lobe system varies in the manner to be expected if the granular stainable material in the cells and their processes is indeed related to hormonal activity The gland is equivalent to only part of the invertebrate system, so possibly other neurosecretory areas may exist (W Bargmann) The form in which the hormones are present in the gland is not certain The full activity of vasopressin and oxytocin resides in *two* octapeptides, but before release into the circulation these are probably attached to a large protein molecule which may be a "carrier" substance Oxytocin may be removed from storage more rapidly than vasopressin, as is seen after parturition and during lactation, *also, oxytocin does not appear to* be made so early in life as vasopressin Thus the two hormones show some measure of independence (C Fromageot) and are remarkable for the apparent rate at which they can be removed from and rebuilt in the gland

Excess of vasopressin is believed by some workers *to* be a factor in causing toxæmia of pregnancy One difficulty in obtaining definite evidence for this view is that several antidiuretic substances can be extracted from blood, or formed from its proteins by enzymes natural to the body These antidiuretic substances are not made by *the posterior pituitary since they can appear* in animals from which the posterior lobe has been removed (H *Croxatto*) A *further difficulty* is that both vasopressin and oxytocin are so potent that they exist in blood in very low concentrations Their estimation is a challenging problem The obvious line of attack would be to collect blood flowing from the gland, since presumably there the hormone concentration would be at its highest Owing to the situation of the pituitary this is more easily said than done, but in cavernous sinus blood more oxytocin than vasopressin is found, which bears out the observation that oxytocin is the more *mobile of the two hormones* There *is a remarkable* interchangeability between the hormones of different and widely separate species of animals, any oxytocin so far examined has always had the same chemical structure Vasopressin is known in two forms In most animals arginine is one of its amino acids, but in the hog this is replaced by lysine Hog vasopressin has far less antidiuretic activity in dogs than arginine vasopressin, but the other activities of the two types of vasopressin are equivalent (H B van Dyke) This fact may ultimately help to unravel the chemical processes whereby the antidiuretic action is triggered The rate of disappearance from the circulation of injected vasopressin is rapid (about three minutes) Once released from the gland the *hormones are destroyed by organs* such as the kidney and liver, and *they are also* partly excreted in the urine (H Heller) The estimation of vasopressin in the urine—*usually as antidiuretic hormone* (A D H)—is one way of determining the conditions under which the endogenous hormone is liberated, thus it appears in *greatly increased* amounts in dehydration, fainting due to blood loss, and emotional disturbances A D H *appears* in the urine of those suffering from motion sickness, *but* not of those who *do not* experience motion sickness, despite swinging and other stimuli, nor is it found as a result of blackout due to acceleration (R L Noble) Thus the pattern resembles that in many experimental conditions, an increase in the osmotic pressure of the blood, excitement, and certain types of volume or pressure change of the circulation, such as may be induced by changes in posture, induce antidiuresis

There is little modern evidence that *vasopressin* ever except during anæsthesia, has the vasopressor action which gave rise to the name it still bears Accordingly it is generally believed that its power to raise blood pressure is pharmacological rather than physiological, but, in rats at least, it may be a factor in causing compensatory vasoconstriction and maintaining blood *pressure after severe* hæmorrhage (M Ginsburg)

Closely allied to the question of *polyuria* is *that of* polydipsia, since in some conditions the *former* is primary and the latter secondary, or vice versa It must be asked, therefore, whether there is a thirst centre comparable *to the hunger and satiety* centres which have been shown to exist in the hypothalamus In goats electrical stimulation of defined areas in the anterior hypothalamus induces immediate and voluminous drinking, whereas destruction *at* certain sites produces complete adipsia *As yet it is not clear whether* the drinking area is an *entity in its own right, but it is* possible to cause simul

been discussed by Best et al,[9] Hench and Ward,[10] Thorn et al,[11] and others *It is now becoming apparent* that the adrenocortical steroids are not the only factors determining the level of the blood eosinophils on the one hand, eosinopenia could be produced in adrenalectomised mice by injecting the plasma of adrenalectomised dogs[12], on the other, "glucocorticoid" eosinopenia could be prevented by giving large doses of heparin[13] But the response of the eosinophils to the administration of adrenocortical steroids can nevertheless be used not only as a method of assay,[12] but also to define the range of biological activity of new compounds Thus, aldosterone is stated to have one third of the activity of cortisone in the eosinopenia test,[14] whereas deoxycortone is inactive[11]

It is apparent, therefore, that an explanation of corticosteroid eosinopenia might well help in understanding the mode of action of adrenocortical hormones Several possible explanations have been advanced Dustin and de Harven[15] suggest an inhibition of eosinophil production in the bone-marrow, and Gordon[16] considers that there is a direct effect on the circulating eosinophils, but recently another interesting hypothesis has been put forward by Esseller et al[17] On the strength of experiments in which the reticulo-endothelial system (R E S) was "blocked" by trypan-blue, they concluded that the "glucocorticoids" acted partly by inhibiting the release of eosinophils from the bone-marrow, and partly by increasing the extent of destruction of these cells by the R E S The possibility that the R E S was at least partly responsible had already been envisaged by previous workers (Thorn[18] for instance), and since the spleen is the most accessible part of the R E S, much attention has been paid to the relation between the spleen and the eosinophils Biggart[6] refers to several workers who believed that eosinopenia is caused by overactivity of the spleen An important observation was made by Opie[3] in 1904 when he noted that the spleen of the guineapig contained a considerable number of eosinophils, which were particularly abundant in the periphery of the pulp but were absent from the malpighian corpuscles The more eosinophils there were in the circulating blood, the more there were in the spleen When, however, the guineapig was starved for five to eight days, the number of eosinophils both in the blood and in the spleen was greatly reduced, but no decrease could be seen in the bone-marrow

Opie's observations have been largely confirmed by later workers, but their significance was not fully appreciated for some time In 1938 Klemperer[19] drew attention again to the fact that the spleen of reptiles, amphibia, and birds (he examined the flamingo) contained many eosinophils, as did the spleen of several humans of varying ages who had all died a sudden violent death, the number of eosinophils in the spleen was proportionately greater than in the circulating blood —partly owing, he thought, to selective migration from the blood stream Allen[20] and Enos et al[21] have noted the disappearance of eosinophils from the human spleen when the patient survived some catastrophe, such as coronary occlusion, for a longer period Enos et al used the presence or absence of splenic eosinophils, in conjunction with changes in the adrenals and in the liver to estimate the approximate survival time of battle casualties in Korea

This phenomenon has now been studied in greater detail by Sevitt[22] By counting the number of eosinophils in sections of the spleen of people who had either died relatively suddenly or whose spleens had been removed within 3–7 hours of an injury, he established a baseline value for eosinophils in the normal spleen The normal spleen contained many more eosinophils per unit volume than the blood, thus confirming the observations of Klemperer[19] Within 24 hours, often even within 12 hours, of severe "stress" in the form of burns, infection hepatic necrosis, &c, the number of eosinophils in the spleen fell progressively, splenic eosinopenia might then persist for several days The accuracy of Opie's observations has thus been fully borne out half a century later

By correlating the changes in the spleen with histological changes in the adrenal cortex and with the level of eosinophils in the blood, Sevitt found that splenic eosinopenia often preceded the loss of lipids from the adrenocortical cells, and that the splenic eosinopenia was in turn preceded by eosinopenia in the blood Since the blood eosinopenia can, with certain reservations be taken as a sensitive index of adrenocortical stimulation it follows that splenic eosinopenia can be similarly interpreted Splenic eosinophilia, however, does not necessarily denote adrenocortical failure Caution is clearly required in drawing conclusions about a dynamic state such as the life of the eosinophil, from a static histological picture, and Sevitt himself noted some apparent exceptions Moreover, the depletion of adrenocortical lipids, the criterion used by Sevitt to denote adrenocortical activity, although useful, is nevertheless only an indirect index As Symington et al[23] have again pointed out, what is seen is variations in the lipid and not in the steroid pattern Despite these limitations, however, it is possible to draw useful conclusions, as Sevitt and Enos et al have shown, and it is probable that splenic eosinopenia, used in conjunction with histological changes in other organs, such as the pituitary and the adrenal glands,[24] will remain of interest and value, particularly perhaps to the forensic pathologist

These observations also raise the question of whether the spleen plays an active part in the production of the eosinopenia—a question of great theoretical interest At present no conclusive answer can be given, but certain experimental and clinical findings are relevant The presence of necrotic eosinophils in the spleen suggested to Sevitt the possibility that this organ either destroyed viable eosinophils or removed degenerate cells from the circulation Degenerative changes in circulating eosinophils had in fact been described in laboratory animals as well as in man[16-5] Padawer and Gordon[25] considered that subsequent ingestion of these cells by the macrophages of the R E S was the normal mechanism of disposal Although the presence of neither the pituitary nor the adrenal glands is necessary for this *destructive process, "stress" or adrenocortical hormones* considerably enhance it An accumulation of eosinophils, under the influence of cortisone, in the spleen of mice has been recorded by Spain and Thalhimer,[26] but the finding has not been confirmed in the rat[27] The fact

Fats and Disease

SINCE the time of THUDICUM,[1] chemists have been systematically engaged in elucidating the complex structures of the lipids found in biological materials Present knowledge of the subject is summarised in simple language in a small monograph by LOVERN[2] and set out more fully in the new edition of HILDITCH's authoritative treatise[3], and these clearly show that the variety of the lipids and the specificity of their chemical constitution is second only to that of the proteins Physiologists have been slow to unravel the biological significance of these differences in chemical structure and only in the past few years have attempts been made to assess their importance in pathology, and especially to appreciate the possible rôle of different fats in the ætiology of degenerative diseases Three weeks ago SINCLAIR[4] indulged in some fascinating speculations arising from the view that the sophisticated diets of modern urban man are relatively deficient in the fatty acids linoleic and arachidonic These acids contain 2 and 4 double bonds and BURR and BURR[5] showed many years ago that they were essential in the diet of rats if growth was to be maintained and dermatitis prevented Most nutritionists have held that human diets are never significantly deficient in these acids, but SINCLAIR thinks that relative deficiencies associated with a high intake of saturated fatty acids and a low intake of vitamin B_6 may predispose to a variety of degenerative disorders including atheroma and myocardial infarction In their article this week Dr BRONTE-STEWART and his colleagues in Cape Town provide evidence, from trials on man, that the nature of the dietary fat affects the lipid content of the serum · oils in which a high proportion of the fatty acids are unsaturated—i e most vegetable oils and those derived from fish and marine mammals—consistently depress serum-cholesterol levels

As ANFINSEN[6] points out, lipids are transported in the plasma and through the extracellular fluids in three forms

1. As chylomicra which are large particles, usually visible under the microscope They are mostly composed of triglycerides, but their detailed chemical architecture remains a mystery
2. As β-lipoproteins, which contain about 25% of protein per particle and include varying proportions of cholesterol triglyceride, and phospholipid
3. As α-lipoproteins, which contain relatively more protein and less lipid and so have a higher density.

It is now established that patients who have had a recent infarction of the myocardium have a high level of β-lipoproteins in their plasma and this is associated with high levels of cholesterol[7] The fact that atheromatous plaques contain large quantities of cholesterol adds circumstantial evidence that the infarction and the disorder of fat transport in the blood are causally related Moreover, studies of the blood-clotting mechanisms have shown that some of these may be intimately connected with fat transport KORN[8][9] has demonstrated that the clearing of fat from the blood after a fatty meal is brought about by a lipoprotein lipase which is a tissue enzyme The enzyme is present in heart muscle and in adipose tissue, and its high degree of specificity of action on the triglycerides of lipoproteins and chylomicra apparently depends on the presence of heparin indeed heparin may possibly be a component prosthetic group of this enzyme ROBINSON and POOLE[10] have been studying the effect of chylomicra, present in the blood after a fatty meal, in making the blood more coagulable, and adduce evidence that this effect is specifically due to the presence in the chylomicra of ethanolamine phosphatide—a substance which resembles lecithin in chemical composition except that the choline base is replaced by ethanolamine Normally ethanolamine phosphatide probably constitutes only 5–10% of the total phospholipid in chylomicra and studies of the factors which may increase this percentage may well provide a clue to chemical processes responsible for pathological thrombosis The specific chemical properties of lipids are now beginning to be related to pathological processes

The great importance of the work of BRONTE-STEWART and his colleagues lies in the assumption that any dietary factor that raises or lowers the level of β-lipoproteins in the blood will also, by implication raise or lower the liability to myocardial infarction. In their experiments on volunteers it was shown that ingestion of beef dripping, butter, hydrogenated ground-nut oil and eggs in large numbers was followed by rises in β-lipoprotein levels in the plasma on the other hand ingestion of olive oil, ground-nut oil, sunflower-seed oil, arachis oil seal oil or pilchard oil was associated with falls in or low levels of, serum-β-lipoproteins Food fats and oils thus seem to fall into two classes whose effects on plasma-lipids are antagonistic to each other If these results are substantiated coronary-artery disease becomes in part a preventable disorder—but at the cost of a complete revolution in our present-day dietary habits The hydrogenation plants of our modern food industry may turn out to have contributed to the causation of a major disease To preserve the unsaturated fatty acids in vegetable oils and marine oils and to make these oils palatable and acceptable to industrial populations would be a herculean task for those who would seek to change people's eating habits All the principles of the modern margarine industry might have to be put into reverse However, comments on Dr SINCLAIR's hypothesis from Professor YUDKIN in our last issue and from Prof ANCEL KEYS this week indicate that systematic knowledge of the ratio of essential to total fatty acids is far from complete for single artificial dietary fats and it is almost non-existent for the total fats consumed in the diets of any large group of persons Thus more knowledge of actual fatty acids in the diets of populations is needed

council's clinics at which no Ministry of Food preparations were sold No other specific statement was made by more than 10% of the respondents as a whole Very few mentioned the general practitioner—2·6% said that the clinic service was better than that given by their own doctor

To the fourth question—"*reasons for first attendance*"—the replies were few and varied 16% said they first attended on the health visitor's or midwife's advice, and another 16% because they wanted help with their first baby Otherwise only 1–2% of the respondents gave any particular reason, but many mentioned their ignorance as to how to bring up a baby

On the third question 86% of the women claimed that they attended "regularly" In reply to this question, 136 reasons were given for not attending regularly (table II)

76% of respondents stated that the service could *not* be improved, while 15% said *that it could* There was no appreciable difference in the replies from voluntary and council clinics, but, as was to be expected, criticisms were far fewer when the clinic was held in suitable premises than when a church hall was used

TABLE II—REASONS GIVEN BY 136 WOMEN FOR IRREGULAR ATTENDANCE AT CLINIC

Reason	No
Only when requiring special advice	9
Child doing well	21
Child older	38
Ill health of mother	7
Other children	12
Children of school age	3
Mother at work	6
Loss time	18
Child ill	8
Times inconvenient	7
Clinic too far away	4
First visit	1
Weighs baby at home	2
1 or first baby only	1
Total	136

Specific suggestions for improvement numbered 114 (table III), these suggestions were made, not only by the 204 respondents who said they thought improvement possible, but also by others who did not The only suggestions made by more than a handful of respondents were (*a*) more frequent sessions and longer hours ([illegible] *respondents*), (*b*) *more staff* (*20 respondents*), and (*c*) less queueing and waiting (*15 respondents*) These suggestions would all seem to amount to the same thing and while they can hardly be regarded as constructive in any detail they merit careful investigation

SAMPLE SURVEY

A random sample of households was visited by the interviewers Of the 306 respondents, 288 were mothers *10 were fathers, and 8 were grandmothers*

The sample was obtained from the records of the housing *authority, which gave the names and addresses of all the* families in these estates with young children Some [illegible] households were originally drawn as the sample, owing to the shortage of interviewers the final sample consisted of [illegible] names and addresses Of these, 8% proved impossible to contact, 7% refused to answer because they were too busy 2% had moved or were on holiday and in 3% of the cases there was no adult female or other suitable person present *This left 80% of the final sample, or 306 cases, as completed* replies

In answer to the question whether the respondent thought child-welfare clinics were a good idea, over 8[illegible]% of respondents, both in those families where there were children under 5 years old and in those where the children were now older, answered "yes," and less than 15% "no" *Of 198 mothers of children under 5* years of age who were questioned, 170 approved of child welfare clinics, and of these, 115 gave reasons (table IV)

TABLE III—SUGGESTIONS FOR IMPROVEMENT OF CHILD WELFARE SERVICE

Suggestion	No
Open more frequently longer hours	[illegible]
More friendly atmosphere, canteen teas, &c	9
More weighing scales, less delay in weighing	7
More staff	20
Warmer premises	4
Less queueing and waiting	15
Better sanitation cleanliness	5
Better seating	3
More regular visits by health visitors to homes	4
Stamps at food centres	6
Orange juice to be paid for in cash	1
Children's old clothes to be on sale	3
Compulsory X ray examination	1
Foot X ray machine	1
Specialists from children's hospitals to attend	1
Sewing classes	1
Cheap foods at each session	3
Other	[illegible]
Total	114

About 35% *of all the mothers* who responded (whether they approved of the clinics or not) thought it was worth while taking the children for expert advice Only [illegible]% said that their reason for approval was the opportunity to get a general check up on the child's progress, and that it enabled them to get the child weighed, this contrasts with the 75% of mothers *at clinics* in the first part of the investigation who gave "check on progress" as their reason for attendance 10% thought the clinic worth while for the inexperienced mother, which agrees with the 16% of attenders at the clinics who said they originally came with their first baby

Thus 86% of mothers approved of welfare centres, but when they or the father or grandmother were asked

TABLE IV—REASONS FOR APPROVAL OF CHILD WELFARE CLINIC NAMED BY 115 MOTHERS OF CHILDREN UNDER 5 YEARS

Reason	No	Reason	No
For advice	37	For welfare foods	4
For inexperienced mothers	11	Doctors are specialists	3
Weighing	10	Better than G P or hospital	9
General check up	7	Hearsay	[illegible]
For first child	7	Other	

of group practice but as a partnership of doctors with home nurses, midwives, health visitors, and home helps. "In uniting public health and general practice we could create something much greater than either separately," and the "new service for community care would become the friendly rival of the hospital service." One of its main objectives, indeed, would be to reduce calls on the hospital, and BROCKINGTON suggests that, except in emergency, it should be responsible for all admissions to hospital, which would enable it to give priority to those patients in greatest social need. The hospital would be used "as a very special instrument rather than a universal salve", and apparently the bed bureau, besides procuring hospital admissions, would arrange for the domiciliary medical teams to give most attention to the people who require it most. As the senior administrative officer, the M.O.H. would coordinate the team, operate the bed bureau, and organise health education. "The records of medical teams and the hospitals, which should be made available to him, would guide the conduct of the community service. In this work he would be immensely aided by the closer association with general practitioners." The problems of community health would be under continual discussion by the doctors themselves in the local medical committee, and BROCKINGTON sets great store by the preservation intact of this statutory body, which has maintained the professional freedom of practitioners under the executive councils and could do the same under local government. "There would be no need to alter the present machinery for payment and appointments, and for dealing with the fortunately few complaints which arise."

One can agree with Professor BROCKINGTON's diagnosis without entirely approving his plan of treatment. In support of his proposal to transfer to local authorities the work now done by executive councils he can quote Sir JOHN MAUDE,[2] who considers such a transfer desirable as a first step towards administrative integration of our tripartite N.H.S. But the other members of the Guillebaud Committee differed from Sir JOHN about this and thought the suggestion would not commend itself to the medical profession.[3] If there were really such a thing as the "general-practitioner service" to which BROCKINGTON refers, the arguments for merging it with the public-health service might be unassailable; but in point of *fact* general practice is conducted not by a service but by individual doctors who have made a personal *contract* with individual patients. The provision of this kind of personal care is perhaps the main contribution of general practice to a world increasingly full of impersonal organisations; and we must beware of even so innocent and rational-sounding a measure as the "coördination of medical teams" should it seem likely to impair the family doctor's sense of personal responsibility. But if there is danger in the organisation of general practice by anyone other than the practitioner himself, it is also true that his patients nowadays often need the help of the various kinds of skilled people whom the M.O.H. can alone provide; and the Society of Medical Officers of Health is obviously right when it says that "medicine in the future can gain immeasurably from a collaboration between the general pract Medical Officer of Health and his staff". can collaboration be further promoted? eral-practice review committee of the British Medical Association thought that "until there is at least a closer and more general administrative liaison between these two branches of the Service some difficulties and misunderstandings will persist".[5] The majority of the Guillebaud Committee, on the other hand, was not persuaded that changes in the machinery were the answer. "The problem of cooperation," they said, "has been tackled more effectively in some areas than in others and ... where integration is lacking the reasons are probably to be found more in the personalities concerned than in any defects of organisation."[3] What is now needed most, we should guess, is more practical demonstrations of what can be done to improve the quality of general practice and public health by the collaboration of people who really care about both. This is the kind of invaluable experiment which does not necessarily depend either on health centres or on more money, but on vision and good feeling. Even a small merger by those keen enough to achieve it under difficulties could be more instructive than a large one imposed by statute; and we hope that Professor BROCKINGTON's arguments will lead many to think further about their local possibilities.

Treatment of Coronary Thrombosis

SCOTTISH *institutions* die hard, and the threat to the future of the *Edinburgh Medical Journal*, first published in 1805, has happily been averted by a union with the *Glasgow Medical Journal* to form a new *Scottish Medical Journal*. It is supported by the four Scottish medical schools and it is appearing monthly. The Edinburgh and Glasgow medical journals have in their day recorded the work and opinions of a great many famous men. In carrying on this task, the editor of the *Scottish Medical Journal*, Dr ALEXANDER BROWN, and his colleagues have the good wishes of doctors in many parts of the world.

The first article in the first issue of the new journal deals with a subject that has engaged the attention of more than one Scottish medical school—the anticoagulant treatment of acute myocardial infarction. GILCHRIST and TULLOCH,[6] of Edinburgh, set out their views after seven years' experience which has convinced them that efficiently controlled treatment with oral anticoagulants has halved the death-rate during the first six weeks of hospital care; and they also believe that the incidence of thrombo-embolic episodes over the same period has been reduced even more. They point out the difficulties of obtaining really comparable treated and untreated groups of patients; but when proper precautions are taken and alternate cases are allotted to treated and untreated groups there is, they say, "a uniformity in the findings which is difficult to challenge". The mortality in a control untreated group from four large investigations works *out* at 29·2%, and the combined mortality for treated patients comes to 16·6%. In the seven years, times, may be largely to blame Undoubtedly there are considerable differences between clinics in respect of progress in health education and the use of visual aids and group discussions This inquiry has, perhaps, suggested some of the ways in which improvements may be possible

Neonatal Mortality

In 1955 the neonatal-mortality rate in England and Wales was 17 3 per 1000 related live births[1] This is the lowest annual rate recorded in this country, the previous record low rate was 17 7 in 1953 and 1954

Parliament

QUESTION TIME

Maternity Services Inquiry

Replying to a question, Miss PATRICIA HORNSBY SMITH, parliamentary secretary to the Ministry of Health, said that the members of the committee set up to inquire into the maternity services were as follows

The Earl of Cranbrook (chairman) Mr G F Gibberd, F R C O G, Mr H J Malkin F R C O G Dr A Beauchamp, Dr W V Howells, Dr J Forest Smith, Dr Jean Mackintosh Miss M Williams, S R N Miss V Shand S R N Lady Pakenham, Mrs Geoffrey Wilson, and Sir Basil Gibson

Chairmen of Health Executive Councils

Replying to a question, Miss HORNSBY SMITH, said that in England and Wales on March 31, 1956, 27 members of the medical profession were chairmen of local health executive councils

Mr CHARLES ROYLE Does not the Minister regard the appointment of doctors as chairmen of executive councils as a rather undesirable practice ? No education committee would appoint a teacher to the chairmanship Will not the Minister make representations to executive councils along these lines ?—Miss HORNSBY SMITH There are 13 lay and 12 professional members on such a committee and they elect their own chairman If in special circumstances they believe that one of their number who happens to be a doctor, or for that matter a dentist, is outstanding for the chairmanship, they are free to elect him Mr ROYLE Does that reply alter the principle ?—Miss HORNSBY SMITH I think that the answer in many cases is that if lay members attended as regularly as some professional members, they would be in a better position to vote for someone else

Mr ARTHUR BLENKINSOP Does not the hon Lady appreciate that there is a point of substance here at which she might well look again ? At the outset of the scheme the Minister appointed the chairmen That was then changed I think that it is highly desirable that executive committees should consider whether they should not appoint a lay person in many cases, unless there are exceptional reasons for the contrary Miss HORNSBY SMITH The vast majority, of course, are lay chairmen

Young Children in Remand Homes

Replying to questions Mr W F DEEDES, under secretary of State for the Home Department, said that the statistics of admissions to remand homes were not kept in a form which would enable him to say how many children were detained in such homes for truancy, and how many were detained between the ages of 8 and 11 years These homes were used mainly for the temporary accommodation of children pending their appearance in court, or while arrangements were made for admission to an approved school

Miss JOAN VICKERS Does the Minister consider it desirable to keep children from truancy in remand homes ? Last year in the home in which I am interested there were 55 such children Will the Minister try to ensure that the young children between the ages of 8 and 11 are not included in the remand homes with the older children who have committed many offences for which they have been brought before the courts on a number of occasions ?—Mr DEEDES The second point in the supplementary question will certainly be borne in mind

Prison Hospital Accommodation

Mr FRANK ALLAUN asked the Home Secretary if he was aware that in the 88 year old Strangeways Gaol, Manchester prisoners confined to bed for long periods with tuberculosis had to be kept in the ordinary prison cells, and that in the hospital of this gaol, holding 1100 prisoners, there were only four one bed rooms for men who must be isolated because of mental or physical sickness, and what steps he proposed to take to provide adequate hospital accommodation in the prison —Mr DEEDES replied The hospital at this prison is admittedly inadequate, but the only solution is to build a new one This will involve substantial reconstruction of other parts of the prison, and will be undertaken when funds can be made available The present accommodation in the hospital proper comprises three wards with thirty two beds and four single rooms In addition there is an extension of the hospital on one of the prison landings of twelve rooms These are not ordinary cells but properly equipped hospital rooms with large windows At present there are 5 cases of tuberculosis in the rooms on the prison landing These cases are under the treatment of a tuberculosis specialist from outside, and are under the immediate supervision of the medical officers and hospital staff of the prison

Mr ALLAUN Would the Minister agree that, whatever a man's prison sentence, his health should not be damaged by it ? Will the Minister therefore ensure that sufficient hospital beds are made available at Strangeways for tuberculous patients and others with serious illness, particularly since as I saw last week, it is extremely difficult for prison officers to carry sick prisoners into the four single bedrooms, two of them padded cells, because of the narrowness of these archaic corridors ?—Mr DEEDES The difficulty is a structural one The grounds of Manchester Prison are completely built up and to build a new hospital it will be necessary to remove a branch of the prison to a site adjacent to the prison, which is now available

Air-pollution Measurements

Replying to a question, Mr J R BEVINS, as representing the Lord President of the Council, said that, under the aegis of the fuel research station of the Department of Scientific and Industrial Research, about 3000 measurements of air pollution were made throughout the day and night during the fog, from Jan 4 to 7 last, in the areas of London, Birmingham Leeds, Manchester, Salford, and Sheffield In the London area the averages of the results for pollution by smoke and by sulphur dioxide were about three quarters of the average during the severe fog of December, 1952, and between three and four times the concentrations in normal winter weather The average concentrations of smoke and sulphur dioxide in the other areas of investigation were about the same as in the London area The concentrations of carbon monoxide in the several areas were not much greater than in normal winter weather The observations were made by more than 500 volunteers, including many from the Civil Defence Corps

Annotations

A NEW MUSCLE RELAXANT

MUSCLE relaxants have so far been used mainly in anæsthesia, where a short duration of action and the need for parenteral injection are not disadvantages A new preparation, zoxazolamine (2 amino 5-chlorobenzoxazole), is active by mouth and has a relatively long action [1-3] It seems to act centrally and to depress the subcortical and spinal polysynaptic pathways It has essentially no action on the monosynaptic arcs, motor nerves, myoneural junctions, or striated muscle Zoxazolamine thus resembles mephenesin rather than the peripheral neuromuscular blocking agents such as tubocurarine or suxamethonium Given to animals, zoxazolamine can produce a flaccid paralysis lasting several hours without a significant change in consciousness, blood-pressure, or respiration Repeated daily, oral doses in rats and dogs produced no cumulative or toxic effects[3]

This new drug has been used in the treatment of spasticity caused by neurological disorders, and some preliminary reports have appeared [4-6] Many conditions have been studied and the results have been variable Clinical observation and electromyographic studies have confirmed that zoxazolamine is a mild muscle relaxant in some spastic states, but its action varies from case to case and even in the same patient at different times Unfortunately reduction of spasticity does not necessarily mean improved voluntary control of limb movements, and it is often achieved at the expense of reduced muscle strength A diminution in muscle tone has been noted, chiefly in patients with spinal cord lesions, and this has been associated with abolition of uncontrolled mass flexion movements and considerable subjective improvement The benefit in patients with spasticity of cortical origin and in paralysis agitans has been inconsistent and indefinite The drug has also been used in patients with muscular stiffness and aching due to rheumatic diseases [7] Side-effects have not been unduly troublesome with doses up to 0 5 g four times a day The commonest have been nausea, vomiting, epigastric discomfort, and dizziness Fever and transient skin rashes have occasionally been noted No blood abnormalities have been recorded

There is no doubt that zoxazolamine has pharmacological properties as a muscle relaxant that make it suitable for long continued administration Chief amongst these are its effectiveness by mouth, duration of action, and low toxicity But the benefit to be achieved by its use in spastic and rheumatic states cannot yet be assessed Zoxazolamine can do nothing to the underlying disease, but by reducing spasticity it may aid physiotherapy and reablement Conditions such as disseminated sclerosis and rheumatoid arthritis are notoriously variable in their course and this makes assessment of the drug difficult, and it seems itself to be rather irregular in its behaviour after oral doses No further conclusions can be drawn on the evidence we have seen so far

MENTAL DEFECT AND HYPSARRHYTHMIA

Prof R S Illingworth [8] has described twelve children in whom severe dementia and convulsive disorders developed rapidly between the ages of four and eight months The striking feature was an abrupt change in social responsiveness, motor and manipulative development were retained to a surprising degree The initial fits were of various types, but later most of the children had salaam attacks Neurological examination revealed no physical signs, but electro-encephalography showed the pattern which Gibbs et al [9] call hypsarrhythmia This pattern consists in bursts of very-high voltage slow waves, together with spike activity which shifts rapidly from site to site the abnormalities are diffuse, and normal patches of record are not found The hypsarrhythmic pattern is common in young epileptic children with massive damage involving the subcortical masses

The disorder described by Illingworth may be less unusual than is supposed because the characteristic epilepsy does not last long, nor does the E E G pattern endure One of the most striking features of the epilepsies of childhood is their sensitivity to maturation Ounsted [10] has shown that the phenotypic expression of the convulsive genotype is rapidly overcome by maturation, and he has pointed out that this is true also of those epilepsies which go with hypsarrhythmia, and which stem from gross anatomical lesions "The anatomical lesions remain, the mental defect remains, the characteristic E E G pattern lingers on, but the fits themselves are inhibited by quite a slight advance in maturity"

Research into the epileptic diseases of childhood has been much neglected in this country Children of the type that Professor Illingworth has described formerly died young They now live on, a burden of hopeless pity to those who care for them

TUBERCULOSIS AFTER PARTIAL GASTRECTOMY

DURING the past decade all too many defects have been attributed to partial gastrectomy, and it seemed that an increased incidence of pulmonary tuberculosis might prove to be one Forsgren [11] was one of the first to show that after partial gastrectomy patients were more liable to pulmonary tuberculosis and that the risk to them might be ten times greater than to the general population In this country Pulvertaft,[12] reviewing Visick's cases, found that of 23 intercurrent deaths from a total of 632 patients 7 had been due to pulmonary tuberculosis and 1 to tuberculous meningitis Bruce Pearson [13] reported 11 cases, 4 of which were found in a follow up of 93 patients, the other 7 were seen as cases of tuberculosis and could not therefore be measured as a proportion of a definite gastrectomy series Tanner [14] was unable to demonstrate a prevalence of more than 5 per 1000 in the 403 patients submitted to mass radiography two to seven years after partial gastrectomy—the rate to be expected in the general public But there were also 2 deaths from tuberculosis and 8 patients under treatment in the 611 consecutive cases of gastrectomy from whom the 403 were selected for mass radiography These last figures are rather against Tanner's view that there is no increased proneness to tuberculosis Allison [15] described 21 cases but gave no indication as to incidence, he suggested that "the faulty assimilation of nourishment together with metabolic imbalance brought about by chemical factors in the body, so lower a person's resistance that tuberculosis is a likely sequel in a certain proportion of patients" Thorn et al [16] have now been more specific They followed 955 patients in whom an X-ray examination of the chest was performed as a routine before partial gastrectomy, and they found that 6 3% had evidence of pulmonary tuberculosis before operation In an admirable

Letters to the Editor

DEFICIENCY OF ESSENTIAL FATTY ACIDS

SIR,—Dr H. M. Sinclair's engaging essay in your issue of April 7 merits more detailed comment that I can supply at this distance from my home laboratory. However, some notes may help your readers appraise the situation in a field unduly beset with conflicting claims and feverish competition.

Besides solving the coronary heart disease problem, Sinclair disposes of lung cancer and leukæmia for good measure, but these latter minor problems I shall leave to others. The central issue of Sinclair's speculations is atherogenesis and the regulation of the concentration of cholesterol in the blood. His thesis is that our present plight in Britain, the United States, and other countries where coronary heart disease is so alarmingly frequent, is due to dietary deficiency of the "essential" fatty acids—linoleic and arachidonic—largely ascribable to the evils of hydrogenation and deficiencies of vitamin E and pyridoxine.

While I join in deploring the increasing use of hydrogenation and many other methods of "improving" our natural foods, I think it can be shown that even in the United States hydrogenated fats are only a small fraction of the total fat consumption, which provides, moreover, a per-capita intake of linoleic acid at least as high as that of many populations, as in Japan, who suffer relatively little coronary heart disease.

The idea that a deficiency of essential fatty acids (E.F.A.) in the diet may be related to atherogenesis is not new; it was suggested a dozen years ago by Dr George Burr, then at the University of Minnesota, and it has been discussed in the United States for several years, notably by another Minnesotan, Dr Ralph Holman of our Hormel Institute. Last year Dr B. Bronte Stewart developed this thesis in South Africa and recently he discussed the question in England. It is well known that animals fed diets extremely deficient in E.F.A.—and such diets are not easy to prepare—often have increased amounts of cholesterol in the liver, but I know of no demonstration of the production of atheroma in these experiments. Moreover, I am unaware of any evidence that a low intake of E.F.A. in the human diet will, by itself, produce either hypercholesteræmia or atherosclerosis. Indeed, even the possibility of E.F.A. deficiency in adults is debated vigorously, and there is not yet unanimity of opinion about the situation among infants, where the best case for the essentiality of E.F.A. has been made—by another former Minnesotan, Dr Arild Hansen.

It is easy to show, as we have been doing for half a dozen years in controlled experiments on man, that merely changing the proportion of calories supplied by ordinary food fats (not hydrogenated) in modern Western type diets promptly results in corresponding changes in the serum cholesterol concentration, even when the intake of calories, cholesterol, proteins, and vitamins is constant. In such experiments, each lasting from four to six months and involving twenty or more men, isocaloric substitution of carbohydrates (sugar, potatoes, and bread) for a large part of the dietary fats involves a sharp reduction in the intake of E.F.A.—and the serum-cholesterol falls and stays down so long as the low fat diet is continued. But when the reverse substitution is made, using lard, butterfat, cottonseed oil, olive oil, coconut oil, or mixed food fats, the serum cholesterol concentration rises. Supplements of vitamin E or of protein (casein) do not alter the result.

These several food fats do not produce quantitatively the same degree of elevation of the serum cholesterol, and a few fats, which do not bulk large in our diets, may have no cholesterogenic effect. We have observed this as well as others, including Kinsell in California, Ahrens in New York, and, recently, Bronte Stewart in South Africa. But the point for the present discussion is that with most of the common food fats an increase in the fat consumption produces an elevation of the serum-cholesterol at the same time the intake of E.F.A. is being increased.

Now it is conceivable that E.F.A. may have no cholesterogenic effect and that large amounts of E.F.A. may counter some of the cholesterogenic tendency of fats containing no E.F.A. But even if this were true it seems unreasonable to ascribe to a "deficiency" of E.F.A. the result of increasing the total intake of fats *and* of E.F.A. (for none of our ordinary food fats are devoid of E.F.A.). I believe it is difficult to ignore the impressive body of evidence leading to the conclusion that our present prevalence of hypercholesteræmia and coronary heart disease would be much altered if we simply reduced the general level of fat in the diet, and that we got into our present plight, at least in part, because we have adopted an increasingly fat rich diet. We are rapidly approaching the time when we must ask seriously what is to be done about it. Dr Sinclair's argument obviously suggests that we solve the coronary problem, without retreating from our high-fat diet, by taking a daily swig of linoleic acid and a few vitamin pills. I wonder whether this is a responsible answer to a serious question.

There are other difficulties with Sinclair's thesis and the facts he adduces in its support. He indicates that Eskimos and "some Norwegians" consume high fat diets but escape atherosclerosis because they eat marine foods in a diet unsullied by the chemist. He forgets that recently[1] he argued persuasively that Eskimos have long since ceased to eat high fat diets. And he seems to be unaware that large amounts of hydrogenated whale oil are eaten in Norway, which is, nevertheless, not among the countries eating the largest amount of fats. (The latter are, more or less in order of decreasing fat as a percentage of total calories: U.S.A., Finland, Australia, New Zealand, Denmark, Canada.) In any case no one knows what may be the freedom, if any, of the Eskimo from atherosclerosis; it *is* known that *coronary-heart disease is a serious problem* in Norway.

Sinclair makes a good deal of cholesterol esters as the villain in the piece. Two facts should give pause here. In the first place, pathologists tell us that the cholesterol esters, as a fraction of the total, are relatively low in newly formed atheroma and that the percentage of esters rises with the age of the lesion. And in the second place, the proportion of ester to free cholesterol in the serum is substantially the same in hypercholesteræmia as in normal or hypocholesteræmia, in coronary patients and in their clinically healthy controls. Further, the amount of cholesterol esters in the liver and in the skin may be interesting, but I do not know that anyone has suggested this as a measure of atherosclerosis.

I feel strongly that a most important clue to the solution of the coronary problem is in the differing frequency of the disease in populations that differ in their modes of life. And I am pleased to learn that Dr Sinclair is agreeing with me that the diet plays a most significant rôle in this. Consideration of the dietary fat and the rôle of cholesterol in the blood transport of this (as lipoprotein) seems to resolve the striking contrasts in the burden of coronary heart disease we have observed in comparing Americans and some Europeans with southern Italians, Sardinians, African Bantu, and Japanese on their native diets. Climate is not the answer, and no more than a minor role can be given to the frequency of obesity in the several populations. If serum cholesterol is the criterion, dietary fat far outweighs differences in physical activity as a causative factor, and we observe that there are plenty of physically inactive men in Italy and here in Japan but,

HEROIN
FROM THE INTERNATIONAL POINT OF VIEW*

P O WOLFF
M A M.D Ph D
HONORARY PROFESSOR OF PHARMACOLOGY IN THE FREIE UNIVERSITÄT OF BERLIN, LATE CHIEF OF THE ADDICTION-PRODUCING DRUGS SECTION OF W H O

DIACETYLMORPHINE or heroin the "wonder drug" of 1898 has been recognised, for several decades as the most dangerous of the opiates—because it so easily induces addiction and because the treatment of that addiction can be so difficult and even perilous

International Action

As long ago as 1923 the Opium Advisory Committee f the League of Nations proposed an inquiry into the uppression of this drug[1] but the main effort began with the conference which in 1931 prepared the Convention for the Limitation of the Manufacture of Narcotic Drugs. A group of four experts including the late Prof W E Dixon and myself, were asked a number of questions[2] In reply we said that heroin was particularly likely to produce addiction because it is "more powerful than morphine and its dose is smaller." because "heroin euphoria is much more pronounced than that of morphine" and because troublesome "constipation does not occur in the addict" We regarded heroin as at least equal to morphine in its pain-relieving action, and as more effective in the relief of cough But we also stated that its addiction-producing properties from the medical point of view, are "much worse" than those of other addiction-producing drugs; we referred to the rapidity with which addiction is induced, to the change in personality with weakening of all the higher mental faculties and to the difficulty of cure We added that we had "evidence that a large majority of the eminent pharmacologists and physicians in various countries are definitely opposed to the employment of heroin in medical practice," and when asked whether the drug is indispensable we said that it "can be entirely dispensed with"

At this 1931 conference unanimity concerning abolition of the production, sale, and medical administration of heroin could not be reached; but Article 10 of the convention contained certain special restrictions on the export of heroin[3]—thus indicating the necessity for particular supervision—and the delegates passed the following recommendation[4]

> The Conference Recognising the highly dangerous character of diacetylmorphine as a drug of addiction and the possibility in most if not all, cases of replacing it by other drugs of a less dangerous character Recommends that each Government should examine in conjunction with the medical profession the possibility of abolishing or restricting its use and should communicate the results of such examination to the Secretary General of the League of Nations"

Year by year the Permanent Central Opium Board and the Drug Supervisory Body (which started their work under the League of Nations and continue it under the United Nations) collected and analysed information on the licit movement of the drug—manufacture, import export, consumption, &c[5] and in 1949[6] and 1950[7] the World Health Organisation's Expert Committee on Drugs Liable to Produce Addiction expressed alarm because production was still on the increase

On the basis of the work of the expert committee and the information collected by the Director-General of W H O, the Sixth World Health Assembly in May, 1953 unanimously expressed its conviction that heroin is not irreplaceable for medical practice, and that the abolition of legally produced heroin by member States would facilitate the struggle against its illicit use It accordingly recommended first, that campaigns should be undertaken to convince doctors and governments that heroin is not irreplaceable, and secondly that member States which had not already done so should cease to produce or import the drug[8]

Having received these recommendations and also one from the Commission on Narcotic Drugs the Economic and Social Council, on July 12 1954 urged all governments to prohibit the manufacture import and export of heroin and asked the Secretary-General of the United Nations to communicate this resolution to all Governments for such action as they might be in a position to take[9]

The Response

How has the situation developed? Whereas in 1949 only 25 countries and 27 non self governing territories had given up the use of heroin in medical practice of the 20 States which have still supplied estimates for heroin consumption in 1956 only 4—leaving aside for the time being the United Kingdom—are not prepared to renounce its use As the World Health Organisation counts some 80 members it is clear that the overwhelming majority of governments are in favour of abolition The Expert Committee on Drugs Liable to Produce Addiction concluded last October that more and more physicians throughout the world are finding it possible to substitute less dangerous drugs for diacetylmorphine in accordance with the committee's repeatedly expressed view on the replaceability of this dangerous addicting agent"[10]

In the U S.A, where the import export and production of heroin has been forbidden since 1924 the government maintains a small stock in case a doctor wants to administer this drug to a patient, but during all these years there have been only two requests for its use In fact the American Medical Association never opposed the ban on heroin rather they recommended its abandonment before the Act was passed In 1917 the Council on Pharmacy and Chemistry of the A M.A deleted heroin from its *Handbook of Useful Drugs*, saying

The Council holds that heroin has no advantage over morphine that it shares every disadvantage of morphine, and that, on the whole its introduction has been harmful, in that it furnished a specious means for avoiding the well founded popular fears of morphine by substituting another habit-forming drug, In 1920 the house of delegates of the A.M.A resolved "That heroin be eliminated from all medical preparations, that it should not be administered, prescribed or dispensed, and that the importation manufacture and sale of heroin should be prohibited in the United States"[10a]

Although there have been sporadic expressions of dissent in the years since there has never been any concerted move to restore the drug Furthermore, contrary to rumours which apparently have spread in London there has been not one request to the American

ECZEMA VACCINATUM

SIR,—I discussed the pathogenesis of Kaposi's varicelliform eruption in a paper[1] which described the virological investigation of 9 cases, including 3 of those reported by Sommerville and his colleagues[2] which were referred to by Dr Napier (Jan 14) in comment on the paper by Dr de Salles Gomes and his colleagues (Dec 17)

Since then I have isolated herpes simplex virus from another 16 cases, including children involved in two outbreaks in dermatological wards, but have not encountered another case of eczema vaccinatum In my experience, in mild cases the eruption may remain confined to areas of skin which *have been* affected by eczema, though it may spread beyond the boundaries of dermatitis active at the time The disease may develop on a basis of unbroken skin in a phase of remission of eczema[1 3]—an observation which supports the hæmatogenous as against the surface contamination theory of pathogenesis Although secondary enlargement is to be expected in lymph-glands draining areas of skin affected by the pustular eruption, another point in favour of the hæmatogenous theory is that adenopathy may not only precede the appearance of the rash but may even be the presenting feature[2 4] The general pattern of the classical case with its incubation period and sudden onset of febrile illness before the development of the eruption resembles that of other virus exanthemata in which viræmia is recognised as an essential stage

A NEW WAY OF TREATING FLAT FEET IN CHILDREN

SIR,—Mr Sayle Creer has long been an authority on this subject and consequently I read his letter (April 7) with interest and great care—perhaps more carefully than he read my article (Feb 11) For though we agree in broad principle and in objective, it is a personal preference that condemns my conception of "flat feet," and there is no foundation for his claim that the device of Mr Charlesworth[5] is similar to my heelseat

He finds with me, though he states the case differently, that if the forefoot is left prone one can correct flat foot by inverting the heel Mr Charlesworth effects this by an admirable heel and arch support which extends to the heads of the metatarsals It is an effective appliance, but to me it has the disadvantage of all arch supports in that it takes weight under the longitudinal arch The original virtue of the *heelseat* is that it produces an arch while the foot bears weight only on the normal three points—viz , the heel and the heads of the first and fifth metatarsals In this way the child's foot is allowed to develop normally, and once the arch is formed the foot is strong Moreover it is important that the floor of the heelseat should not be wedged, for it is the weight of the child on the level surface which keeps the walls of the heelseat vertical and therefore maintains the position of the heel If the base is wedged the heel slides to the outer side and produces the problem that Mr Charlesworth discusses

Mr Sayle Creer has quite reasonably given himself the prerogative of limiting the definition of "flat foot" to the foot with a flattened longitudinal arch To all other flat feet in children he refers as pronated, everted, or valgus feet With many other orthopædic surgeons, I am content to say that the feet are flat in any child that walks on the inner borders of the feet—whether the condition is due to a congenitally flat longitudinal arch or acquired by "everting the heel of an otherwise normal mobile foot" The difference is one of terminology only, and perhaps for the purpose of the article, which is to describe a method of treatment, Mr Sayle Creer will permit both types to be called flat feet—for if he will try the heelseat with persistence he will find that even the congenital flat foot can so be treated

Judging by the number of queries that I have had from many parts of the world, I am happy and relieved to find that the "heelseat" seems to be regarded as both original and useful by orthopædic surgeons, pædiatricians, and specialists in physical medicine

MYASTHENIA GRAVIS

SIR,—Your editorial last week reveals a remarkable failure to understand the significance of recent investigations into the defect of neuromuscular transmission in this disorder Thus, you state that the conclusions we drew from the response of myasthenics to the administration of decamethonium are opposed to those of Grob et al ,[1] which are based on the effect of the intra-arterial injection of acetylcholine It is with the intention of correcting the confusion of thought that must have been created that we should like to re-state the generally accepted interpretation of these results

Decamethonium (C10) has been shown to act at the myoneural junction in a similar manner to acetylcholine[2] but with the difference that because it is not rapidly destroyed by cholinesterase its actions can be readily studied Using this drug in cases of myasthenia we demonstrated[3] that, whereas in normal subjects it acted as a pure depolariser, in myasthenics it acted by *a fleeting depolarisation followed* by a more prolonged non-depolarisation (i e , curare like) block—the so called dual response The fact that in myasthenics, as in normal subjects, decamethonium can be recovered unchanged from the urine indicated that the abnormal response to *decamethonium* was a *property* of the motor end plate. On the basis of these results we put forward at that time the theory that the underlying mechanism at fault in myasthenia was an alteration in the manner in which the motor end plate responded to acetylcholine or one of its breakdown products

In 1955 Grob and his colleagues reported the results of their work using the intra arterial injection of acetylcholine In essence, they found that the response in both normal and myasthenic subjects was in two phases first, a prompt depression of muscle activity (depolarisation block) which lasted about a minute and was soon followed by a secondary depression which persisted for thirty to sixty minutes This late depression was found to be identical with the effect of the injection of choline—a breakdown product of acetylcholine Furthermore they noted that, whereas acetylcholine produced a rapid depolarisation block in both normal and myasthenic patients, choline gave rise to a depolarisation block in normal subjects and a non-depolarisation block in myasthenics In other words, the injection of acetylcholine in myasthenic subjects gives rise to a "dual block"—i e , a fleeting depolarisation block (due to acetylcholine) followed by a *prolonged non* depolarisation block (due to choline) On the basis of their results these authors were unable to say "whether this abnormal response was due to a change in the myasthenic end plate itself, or to the formation in myasthenic patients of a product of choline which is a *competitive* blocking agent" However, after comparing our results with their own they conclude "this suggests that the myasthenic end plate may react abnormally " ecently developed drugs are methadone ('Physeptone' inctus) pholcodine (which has to be classed with codeine) and dextromethorphan (known as 'Romilar') This last product is said to have no side effects, to maintain its efficiency over long periods, and not to induce addiction t does not prevent the coughing up of phlegm or alter the consistence of the sputum[20] and it has no analgesic action It seems to be much used in the U S A

Analgesic

Besides the more familiar drugs such as hydromorphinone ('Dilaudid') pethidine methadone ('Physeptone'), and phenadoxone ('Heptalgin') I should like to draw attention to levorphan (which in Great Britain formerly had the generic name methorphinan and is known as 'Dromoran') In chemical structure it is closely related to morphine but its analgesic effect lasts longer than that of morphine, and consequently much longer than that of heroin—which is helpful in the treatment of chronic pain Its side-effects, including constipation, are less than those of morphine and it also has the advantage of being effective when given by mouth Other synthetic analgesics including pethidine and methadone are also effective by mouth but often cause nausea and vomiting whereas levorphan is generally well tolerated (For many years I have insisted on the need to avoid injection of analgesics, so as not to create a "needle habit" in potential addicts[21]) At the New York session of the Commission of Narcotic Drugs in April–May, 1955 Dr N B Eddy, chief of the section on analgesics, National Institutes of Health Bethesda, Maryland described levorphan as "as effective an analgesic as heroin" and "as effective as morphine in the treatment of cancer[21 22] Therefore it seems to me that this drug deserves more consideration

Conclusion

On a question so complex as that of heroin, there cannot easily be unanimity Personally I have always recognised that in Great Britain there will be no danger to the public if heroin remains available in the future under the same conditions as at present The British physicians and surgeons—probably mainly the older generation—who are accustomed to administering heroin after surgical operations or otherwise know how to manage this dangerous tool On the other hand reliable sources have repeatedly confirmed to me that the younger colleagues, as in other European countries, do not use heroin any more Moreover, when it is given to relieve cough, there is no great risk that heroin addicts will drink whole bottles of linctus or cough mixture for what they really look for is an intravenous injection or a chance to sniff their drug If there were not a world-wide danger and an urgent request for coöperation by all countries—including the very few which have not yet agreed to abolish heroin—nobody would bother about the availability of heroin in the U K

On the other hand, the history of therapeutics has shown repeatedly that remedies held in great esteem are rejected when better ones have been found I believe that heroin is now ripe for replacement

I am hoping therefore that the British medical profession will agree to give up the use of this drug I ask those doctors favouring heroin to re examine the truly practical possibility of relieving extreme human pain without it As the Home Secretary said last July, there is certainly a "need for an international effort to mitigate the heroin problem"[23] and in my view it is important to continue the efficient international coöperation over addiction-producing drugs which was started under the League of Nations To abolish the use of heroin even where there is no national necessity to do so would be a valuable contribution to the idea that nations should work together for the common good.

NUTRITIONAL STUDIES IN A MENTAL HOSPITAL

Z A LEITNER
M.D Berlin
L.R.C.P.E

I C CHURCH
M.R.C.S D.P.M
LATE PSYCHIATRIC REGISTRAR

From Claybury Hospital Woodford Green Essex

In general hospitals the turnover of patients is quick, and during their stay their diet often depends on their ailment In mental hospitals, on the other hand because patients stay longer the diet is often even more important We briefly describe here some of the results of nutritional studies at Claybury Hospital

Material and Methods

During the greater part of this investigation patients in Claybury Hospital numbered about 2300, with a preponderance of females About half of the women and a third of the men patients were over 65 years of age The admission-rate is about 1300 per annum and each year just over 1000 patients are discharged

The main part of our investigation was carried out between May 1951, and May 1954 As far as possible we selected ambulant cases in apparently good physical health (all patients with recent feverish illnesses were excluded) who had been inpatients continuously for at least two years but we also included some newly admitted patients

A general nutritional survey was carried out during the whole time of the study including control of nutritional intake and body weight and a larger proportion of the ambulant hospital population was regularly examined with special regard to symptoms and signs of early deficiency states (Leitner 1948)

All laboratory investigations were carried out after careful study of the case history and after clinical examination In many cases estimations were made of total carotenoids vitamin-A reserves (Kimble 1939), vitamin E reserves (Quaife and Harris 1944), vitamin-C reserves (Harris and Abbasy 1937), hæmoglobin level (Evans photo-electric hæmoglobinometer) prothrombin-time (Quick 1936) and petechiae counts (Hess and Fish 1914)

The greater part of this investigation was carried out while essential foods were still rationed At first we were tempted to follow the conventional quantitative food survey—to weigh and analyse sample meals and to deduct the remains on the plate But apart from the fact that the resources were insufficient for such an investigation we felt that it would only have specious precision and singling out one particular ward for weighing and analysing meals for, say, a week might yield a misleading result as regards the hospital in general or even the selected ward in another week

We therefore adopted a seemingly less exact method. The amount of food delivered to the central kitchen was carefully measured Milk, meat and fish (fresh and made up) and cheese were always weighed again before being sent to the wards Fat and sugar were rationed, bread and potatoes were plentiful Marmalade jam, green vegetables, and fruit were scarce and they were therefore fully consumed. Our practice was to instruct repeatedly the ward sisters in several wards simultaneously to collect and preserve daily all the waste from the plates for consecutive periods of two to three weeks The remains were carefully measured We came to the by any method, due to the difficulties of following up a series of cases in a moving population, and determining the frequency of complications which may arise many years after the original injury. Further, the disease is primarily a disease of the active years of life and does not occur in children or in the elderly, with the sole exception of epileptics. It is, therefore, not so easy to collect even in a busy clinic an adequate number of cases, for an essential part of the investigation must be a study of the mode of treatment employed in the reduction of the dislocation. This you do not mention.

It is quite probable that in the past Kocher's manœuvre as carried out under insufficient anæsthesia contributed a considerable quota of cases. Since the use of thiopentone and modern relaxants, the ease with which a shoulder can be reduced has been so increased that no additional capsular damage need be done in the majority of cases, and it is my impression that the frequency of recurrence is slowly declining.

Even if one could collect a group of cases in the appropriate age group reduced by the same method and treated by alternate fixation and immobilisation, one's conscience might trouble one, as one cannot suggest a method of investigation which would not impose a hardship on the patient. Even if the recurrence-rate were as high as one in ten, an individual, faced with the choice of three weeks' immobilisation to avoid that risk and the certainty that if a recurrence did occur a straightforward operation followed by three weeks' immobilisation and perhaps a further three weeks' rehabilitation would cure it, would prefer to take his chances of having to be immobilised later rather than immediately.

I have tried to make some comparisons between the methods in the past and have been defeated by the almost instinctive resistance of the patient who when he feels his shoulder is right will take it out of his sling and use it regardless of the advice given to him. In my experience one of the surest ways of losing a young patient from the clinic is to immobilise him for three weeks after a dislocation. Only a few of the more phlegmatic patients will continue under this régime without raising question.

This is an interesting clinical problem but it appears it will only be solved by central registration of dislocated shoulders, uniformly treated, and a further registration of their recurrence. When the answer would appear to warrant this, I have no doubt somebody will find the necessary energy to answer your questions.

London, W.1. J. G. BONNIN.

BREAST CHANGES IN FIBROCYSTIC DISEASE OF THE PANCREAS

SIR,—Dr. Stroud and Dr. Heppleston, in their letter last week, illustrate the changes in the breast of a 6-week-old child, and conclude that the enlargement was due to "mastitis neonatorum." With this conclusion I entirely agree (though I dislike the term), and there is no need to invoke "mucoviscidosis" or antibiotic therapy.

I have examined histologically the breasts of many infants aged 0–6 months, and in a series of 115 such infants the histological picture illustrated by Stroud and Heppleston was found 15 times. This series was collected in the immediate post-war period, when the only antibiotic in general use was penicillin. This particular histological picture was not the only one responsible for enlargement, although the largest breasts usually showed this appearance. A secretory picture similar to that of the lactating adult breast is also common, and may produce quite considerable enlargement. The cystic change illustrated by Stroud and Heppleston may be a stage in the normal progression from the secretory to the resting (prepubertal) phase, since it was found to have a maximal incidence about the 2nd–3rd week, while the secretory picture was found maximally in the first 7 days of life. The prepubertal picture does not appear until the 4th week onwards. The oldest case showing the cystic appearance was 18 weeks. Pictures intermediate between secretory and cystic, and between cystic and prepubertal, were found in 14 of the 115 cases.

I have no details of antibiotic therapy in these cases, but there appeared to be no correlation with any particular disease process, and the sex-distribution was equal—8 boys and 7 girls.

Department of Pathology,
Bedford General Hospital. J. C. VALENTINE.

⁂ Through a misunderstanding of ours it was stated in the letter by Dr. Stroud and Dr. Heppleston that case 1 was one of Dr. Jolly's three cases (*Lancet*, 1955, ii, 1136). In fact cases 1 and 2 were seen in the department of child health of the Welsh National School of Medicine.—ED. L.

FLUIDS FOR INTRAVENOUS INFUSION

SIR,—For some years I have used a brand of vacuum-bottled sterile intravenous infusion fluids and have felt able to rely on these products. Within six months I have found a faulty vacuum in four bottles (isotonic saline three, isotonic saline/glucose one) and in one of each the pressure was a little above atmospheric. Apparently complaints of this kind are rare. I have heard of no similar experiences. Every bottle that I use I open myself, and I wonder if such faults are missed when nurses open bottles and either do not appreciate or do not report the defect.

The method of bottling used by this firm makes it hard to see how the vacuum can fail, and no one so far has given a satisfactory explanation of the origin of a pressure above atmospheric (around 10 cm. of water in one case). I would urge anæsthetists and others setting up "drips" to watch for a lack of bubbling (or for frank squirting out of the solution) when the caps are removed from such bottles, and not merely to discard them but to report such events to the makers.

London, E.11. JOHN BARNARD.

HÆMATEMESIS

SIR,—I feel that Dr. Bancroft's comments (April 14) on my article (April 7) are reasonable and should be answered.

The method was used, in the first instance, only on the very late case of hæmatemesis—the case that almost invariably ended fatally. It was used, therefore, as an alternative to emergency gastrectomy and was found to give better results. The only remaining procedure for obtaining direct controls would have been to retain 50% of these patients on a régime which had already failed.

The most positive proof I can offer is the way in which patients who have failed to respond to routine medical treatment cease bleeding after the administration of adrenaline and 'Stypven.' This statement can be confirmed or discredited only by an actual trial of the method. We found at an early stage in the investigation that gastric lavage and stypven in doses of up to 20 ml. were often ineffective, yet when repeated in conjunction with adrenaline the bleeding was immediately controlled—though, as I discovered subsequently, only temporarily in a proportion of cases of true "surgical" hæmatemesis.

The main point at issue for the physician and surgeon alike is to recognise "surgical" hæmatemesis early. As a rule patients are transferred to a surgical ward for one of two reasons: either because they comply with the standard criteria for surgery, or because they will not respond to medical treatment after the most patient and persistent endeavour. In the first instance we observed a 30% error in diagnosis, and in the second the results of operation were not encouraging.

on the outer side of the arm, or in the clavicular region gingivitis and stomatitis with hypertrophy of the dental papillæ were common, but boggy, tender, bleeding gums were restricted to the few patients who had retained their teeth. Petechial hæmorrhages and ecchymoses, with extensive bluish purplish discoloration on the lower legs and ankles and occasionally on the forearms, were found in a group of male patients working in the gardens, but in none of the women who had a prevalently sitting occupation.

Petechiæ counts were performed in 278 of these 460 patients. As has been repeatedly noted (Medical Research Council 1953) the number of petechiæ was unrelated to the vitamin-C reserves.

Discussion

The nutrition of the patients in the hospital was such that gross deficiency states were uncommon. This is the more gratifying because several patients included in the investigation had been continuously at Claybury for fifty years or more. Only just over a decade ago, as many as 10 cases of frank pellagra were found in a few months in a single mental hospital (Hardwick 1943) (and 5 further cases were found within the same period in two general hospitals [Rimington and Leitner 1945]). During the present investigation only 3 cases of fully developed pellagra were seen, and 1 of these was in a newly admitted patient with florid scurvy.

While clinically obvious gross deficiency states were infrequent, detailed study disclosed "latent" deficiencies. In old people mucous membrane changes are usually more or less readily detected, but skin changes, gingivitis in edentulous elderly patients with neglected mouths and with atrophied and shrunken structures are more difficult to recognise, and they may occasionally be absent even in cases of advanced deficiency. Although the food was calorically sufficient and contained enough protein the nutritional status in carotenoids, vitamin A, and vitamin C was unsatisfactorily low, leading in many cases to deficiency states which were bound to impair general health.

The urgent need to reorganise catering arrangements in mental hospitals has been emphasised by Harington Hawes (1955). We support this timely proposal, although we are not convinced that fulfilment of such a programme would necessarily eliminate all the inadequacies found in the diet of our patients. We suggest that meanwhile the present scanty supply of vegetables (such as carrots, spinach, kale, leeks, turnip greens, tomatoes) should be enhanced by increasing the yield of the farms attached to many mental hospitals, and that each patient should be given routinely one 50 mg tablet of ascorbic acid daily. We are aware that 30 mg of ascorbic acid in the daily food provides a satisfactory margin of safety for the average person (League of Nations 1938). In mental hospitals, however, some patients, although without obvious symptoms and signs of disease, and perhaps only with occasionally recurrent mild attacks of diarrhœa or steatorrhœa, are far below average health, and may even be unable to absorb or to utilise nutrients satisfactorily (Boscott and Cooke 1954).

In our opinion any addition to the diet of a purified vitamin (such as ascorbic acid) is at best only a poor substitute for proper food, and this practice ought to be eliminated as soon as circumstances permit. But in our large mental hospitals we are faced with an unusually difficult and complex problem: many of the kitchens are old and their equipment obsolete, the financial allowance for food is limited, and often the patients, because of their mental disorder, are uncoöperative. Our studies have convinced us that even the most appetising diet will not be taken by some of these patients at all regularly without supervision and coaxing by specially allocated nursing staff. This supervision seems to be out of the question while the prevailing shortage of personnel persists, even if the financial resources were forthcoming. Addition of ascorbic acid seems to be the only immediate remedy for the poor vitamin-C intake in our mental hospitals.

Summary

A three year nutritional survey in a mental hospital, combined with laboratory investigations, showed that the food provided sufficient calories, but the patients' hæmoglobin levels and their nutriture in carotenoids, vitamin A, and vitamin C were low.

It is suggested that all patients in mental hospitals should be given 50 mg of ascorbic acid daily, and that the supply of leafy green vegetables should be substantially increased.

We thank Dr J S Harris, physician superintendent, for his help throughout this investigation, and Dr George Graham for suggesting it. Our thanks are also due to the medical, nursing, and laboratory staff of the hospital, especially Mr F C Radley and Mr G W Swyers. The part of the work dealing with vitamins A and E was planned and carried out in constant cooperation with Dr T Moore and Dr I M Sharman, to whom we are particularly grateful for much advice and help. Dr Margaret Briggs, of Roche Products Ltd, kindly supplied the ascorbic acid needed in the investigation.

FAMILY PLANNING ASSOCIATION

On April 17 the Family Planning Association held in London an "Any Questions" meeting on Parenthood by Choice or by Chance, with Mr C H Rolfe, of the *New Statesman*, in the chair, and Mr J D Bronowski, PH D, Mr Julian Huxley, D SC, F R S, Lady Pakenham (who represented a Roman Catholic viewpoint), Canon Mervyn Stockwood, and Mrs Mary Stocks answering the questions.

The questions ranged widely from the need for birth-control to combat the effects of death control to the ethical dilemma of the stage at which "interference" with reproduction might be allowed to take place. Most members of the panel thought that some degree of birth-control was inevitably necessary in all parts of the world, because the world population was increasing more rapidly than any possible increase in food production. With one exception they agreed that the discovery of a simple and infallible contraceptive would not be a danger to the human race. Dr Bronowski thought that the birth rate depended on the economic stability of a country, and the ability of parents to have a feeling of fulfilment in their children; when they felt able to do so they tended to have enough or more than enough children to maintain the population. Canon Stockwood

Obituary

ARTHUR HUGH McCULLOCH EATON

M B Belf, F R C S E

Mr Eaton, senior surgeon to the Tyrone County Hospital, died on April 1 The youngest son of the late Mr and Mrs J C Eaton, Altnagelvin, Derry, he was educated at Foyle College and Queen's University, Belfast He served in the 1914–18 war as a surgeon probationer in the R N V R, and on demobilisation he returned to Queen's and graduated with honours in 1922 After taking the F R C S E in 1927, he was appointed as surgeon in the Tyrone County Hospital, Omagh As a Territorial officer he was called up in 1939 and he served in Boulogne until the evacuation in 1940 At the request of the Tyrone hospital committee he was recalled to his civilian post before the end of the war He served as president of the Northern Ireland branch of the British Medical Association, of the Omagh branch of the British Legion, of the Tyrone branch of the British Red Cross Society, and of the Tyrone County Club He was also a member of the Tyrone Grand Jury

W S B writes "Mr Eaton was one of the small band of surgeons working in country hospitals in Ulster who bore the brunt of surgery for so many years until the introduction of the health service The fact that his hospital, from small beginnings, became one of the largest Ulster hospitals outside Belfast was due to his continued efforts, administrative skill, and personality, as well as his surgical skill He was a quiet and unassuming man who, despite the early age at which he took up his appointment, foresaw the possibilities of development in country-hospital work Such were his sound common sense and the confidence that he inspired in his hospital committees that he was able to build up outpatient clinic organisations and form a nucleus of a fuller medical staff, so that when the consultant and specialist services were introduced at the beginning of the health scheme his hospital was already well developed and able to take a full part from the beginning in the new era In a provincial hospital the tie between staff, patients, and local people is, in many ways, stronger than in any of the larger city institutions, and Mr Eaton will be sincerely missed, not only as their medical adviser but as their friend, by the great numbers of people who had benefited from his ceaseless hard work and kindly advice"

He leaves a widow and two daughters

ALEXANDER GIBSON

M A, M B Edin, F R C S E

Dr Gibson, consulting orthopædic surgeon to the Winnipeg General Hospital, whose death at the age of 73 has been announced, was one of the many distinguished emigrants whom Scotland has sent to Canada

He was born in Edinburgh and educated at the university there, graduating M B with first-class honours in 1908, and winning the Vans Dunlop and Ettles scholarships He held a university demonstratorship in anatomy before he came to London to continue his surgical and anatomical studies After taking the F R C S in 1913 he was appointed to the chair of anatomy in the University of Manitoba During the first world war he served with the Canadian Forces in India and Egypt, and during the late war he was in charge of a Canadian Red Cross unit in Scotland He was a past president of the Canadian Orthopædic Association and surgeon in charge of orthopædics at Winnipeg Military Hospital

An English colleague who had met him at meetings in London and Quebec writes

"For many years Alexander Gibson's name has been familiar to orthopædic surgeons in this country from his publications, particularly in connection with the surgery of the hip joint, though for many of the younger generation the first chance of the pleasure of his personal acquaintance came on his visit to Britain in 1952 for the Orthopædic Meeting of the English speaking World—and it was a real pleasure He had the gift of friendship His writings were lucid and he was a most admirable speaker, forceful and clear in the best Scottish tradition With our colleagues in Canada we share a sense of deep loss of a fine surgeon and a fine man"

Diary of the Week

APRIL 29 TO MAY 5

Monday, 30th

Manchester Medical Society
4 30 P M (Medical School, Manchester University) Prof A Stampar (Zagreb) Public Health in Underdeveloped Countries

Postgraduate Medical School of London, Ducane Road, W 12
4 P M Dr Ian Gilliland Exophthalmos

Tuesday, 1st

Royal College of Physicians of London, Pall Mall East, S W 1
5 P M Dr A H Douthwaite *Pitfalls in Medicine* (First of two Croonian lectures)

University of London
5 30 P M (London School of Hygiene and Tropical Medicine Keppel Street, W C 1) Prof L Kreyberg (Oslo) Ætiology and Occurrence of Lung Cancer in the light of Pathological Anatomy

Royal Society of Medicine, 1, Wimpole Street, W 1
8 30 P M *Orthopædics* Sir Reginald Watson Jones Treatment of Bone and Joint Injuries—past, present, and future (Presidential address)

Institute of Child Health
5 P M (Hospital for Sick Children, Great Ormond Street, W C 1) Dr J H Ebbs (Toronto) Changes in the Stature of School children in the last Half Century

Wednesday, 2nd

A memorial service for the late Sir Morton Smart is to be held at the Savoy Chapel, London, on Wednesday, May 2, at 11 45 A M neous drinking and antidiuresis owing to the overlap the two regions (B Andersson) Pituitary resistant abetes insipidus is known to occur in man, and for this ason among others it is of interest to discover just where the kidney A D H acts to cause water reabsorption the rat, urine can be collected by micropuncture from me parts of the distal convolution of individual ephrons In all instances, whatever the concentration f the bladder urine, tubular urine from the first part of he distal convolution is hypotonic to plasma , the final rocess of concentration must therefore occur distal to his point—i e , in the latter part of the distal convolution nd perhaps also in the collecting duct (H Wirz) A imilarly hypotonic urine is found in the distal con-olution of certain anurans which lack a thin segment of he loop of Henle, though the kidneys of these animals an concentrate under the influence of posterior-pituitary ormone (W H Sawyer) There is agreement, then, that oncentration of urine due to vasopressin occurs in the istal part of the distal convoluted tubule, but it is ncertain whether concentration also takes place in the ollecting ducts

It is in relation to oxytocin that a number of new ossibilities are appearing So far this substance is nown to affect uterine activity and milk ejection only, et it is released from the gland in many circumstances nd in greater quantities than is vasopressin , and it is ormally present in the gland in equal amounts in males nd females It can be shown that the administration f oxytocin by itself may greatly affect blood-flow hrough, and sodium excretion by, the kidney and that hen both vasopressor and oxytocic hormones are given together, in proportions in which they may well be released in the body, they have effects on sodium excretion not seen when either is given alone (F P Brooks and M Pickford) It is unknown whether the action on the kidney is direct or dependent on an intermediary For functional as well as anatomical reasons it is possible that oxytocin has some action on the anterior pituitary For instance, although after parturition total absence of suckling allows mammary involution, in rats, if some mammæ are used and some are not, the unused ones do not involute, suggesting that suckling is the stimulus to a reflex release of prolactin which maintains alike the used and unused glands Moreover, if oxytocin is given to rats with diabetes insipidus (i e , with no endogenously produced oxytocin) the expected mammary involution does not occur Suckling undoubtedly stimulates the posterior lobe to release oxytocin, which may then reach the anterior lobe via capillary vascular connections (A T Cowie and S J Folley)

Another important function of oxytocin may be in aiding the transport of spermatozoa from vagina to fallopian tubes The known rate of movement of spermatozoa cannot account for the speed with which they reach the upper end of the genital tract , and there is good evidence for increased uterine movement in response to coitus Now comes the observation of an apparent increase in the oxytocin content of jugular blood in cows when the uterus is stimulated manually Taken in conjunction with the known action of oxytocin on the uterus, this suggests that coitus causes a reflex liberation of oxytocin which in turn induces coordinate movements of the uterus so that the sperms are swept rapidly along the genital tract towards the ovum (R J Fitzpatrick) Confirmation of this will depend on a suitable method for extracting oxytocin from blood, and there is some hope that a satisfactory method may be perfected Already there are indications that oxytocin is present in jugular blood in greater amounts than vasopressin This would agree with van Dyke's findings on the content of cavernous sinus blood, and with the many functional studies which point to an always greater liberation of oxytocin than of vasopressin (J M Walker)

Finally, if the posterior lobe can influence the anterior lobe it may indirectly affect the adrenal cortex Some link between them is suggested by the fact that certain types of stress known to affect the adrenal cortex at the same time deplete the posterior lobe of its A D H Further, hydrocortisone seems either to speed the replenishment of the posterior lobe or to inhibit the release of A D H In adrenalectomised rats hydrocortisone also protects the posterior lobe against the severe effects of dehydration (R Gaunt, J J Chart, and C W Lloyd) There are still other pointers to the interaction of the posterior lobe and the adrenal cortex Thus, an adrenalectomised rat with diabetes insipidus has an almost normal plasma-sodium concentration, but if the animal is treated with A D H its plasma sodium falls , and a rat with diabetes insipidus shows less loss of ascorbic acid from its adrenal cortex in response to a stress stimulus than does a normal animal, but it can be made to react in an almost normal manner by preliminary treatment with vasopressor posterior lobe extract (I Chester Jones)

This is an impressive list of activities for a gland whose function was unknown sixty years ago Recent work suggests that the list is by no means complete

The whole symposium with the discussions is to be published as a book

Occasional Survey

EOSINOPHILS AND THE SPLEEN

SINCE Paul Ehrlich described the eosinophil leucocyte as a distinct structure, a great deal has been written about this mysterious cell. The literature on this subject shows a curious shift of emphasis earlier authors—for example, Ringoen [1]—were largely concerned with the phenomenon of eosinophilia , more recently, since the introduction of corticotrophin and the adrenocortical steroids, it has been eosinopenia which has attracted more attention But some of the crucial facts about eosinopenia came to light fairly early in the story of the eosinophil Ehrlich himself was already aware of the considerable decrease in the number of the blood eosinophils in "ordinary polynuclear leucocytosis," [2] an observation which led many European hæmatologists to regard the subsequent eosinophilia as the *Morgenröte* of impending recovery from an acute infection

As early as 1904, Opie [3] described eosinopenia in the guineapig under experimental conditions which today would be interpreted as "stress", and Schwarz,[4] in 1914, and Borchard,[5] in 1928, drew attention to the role of the suprarenal glands in the production of eosinopenia Yet it was easier to interpret eosinophilia in terms of a "positive chemotaxis" than to explain eosinopenia by "negative chemotaxis" [2], and later work on the rôle of the eosinophil in protein metabolism [6] offered a key to the understanding of eosinophilia, whereas the observations on eosinopenia remained largely unrelated Only when Dalton and Selye [7] noted eosinopenia in "non specific stress" could these isolated observations be drawn together, and this finally led to the introduction of the Thorn test [8] (the response of the blood eosinophil level to the administration of corticotrophin) The limitations and the usefulness of this test have recently would otherwise exist between the top of the fireplace and the top of the guard

As an alternative to drilling holes in the fireplace, the studs can be mounted on rubber suction discs The sucker shown in the accompanying inset figure was hardly good enough, but a better type which is used in a range of car accessories would give a very firm grip on a tiled fireplace Perhaps some manufacturer of fireguards would consider this idea

A BROCHURE FOR THE YOUNG PATIENT

Few attempts are made to write intelligently on medical matters for young people of 12–16 Perhaps this is because they are a between age group, neither child nor adult, for whom the English language does not even provide a generic name "girl" is acceptable but "boy" barely so, and the two together fail to convey the right impression, "teenager" is American and in this country is applied generally to the 15 or 16 plus We glance at them charily, and as subjects for medical literature pass them by with scarce a thought They are not often seriously ill, they are seldom grouped together in a ward, and they have little opportunity of asking for information Should we therefore ignore them? It has been the custom to do so, and custom is hard to change A brochure designed especially to appeal to them pulls us up with a jerk

The Brentwood Hospital Management Committee, with the help of the National Association for the Prevention of Tuberculosis, have produced such a brochure[1] for young patients who come to Highwood Hospital for treatment While the result is not beyond criticism, the intention is unreservedly commendable, the effort to win the young patient's cooperation is a compliment that he will appreciate The main objects of treatment are explained and the idea behind such treatment is conveyed—albeit rather haltingly There is a tendency to talk down ("Be a good patient and do what the doctors and nurses tell you") which may arouse resentment, too much is in the abstract (as in the differentiation between "negative distractions" and "positive distractions"), and there is rather too much of the phraseology applicable to adult tuberculous patients ("tearing your nerves to pieces with worry," "imposing a kind of self discipline," "you have to be a social and a human being") But the basic idea is fundamentally right

---

University of London

Dr E M Glaser has been appointed to the readership in physiology at the London Hospital Medical College

Dr Glaser qualified from the University of Bratislava in 1939 and soon afterwards came to this country where he became a voluntary research assistant at the British Postgraduate Medical School During his service with the R A M C in the late war he received the M C In 1949 he took the PH D Camb and in 1951 the M R C P As a member of the Medical Research Council's scientific staff he worked in the department of experimental medicine at Cambridge Since he took up his present post as King Edward professor of physiology in the University of Malaya he has continued to serve on the M R C 's standing advisory committee on climatic physiology His published work includes papers on the prevention of motion sickness

Dr J C Sloper has been appointed to the readership in morbid anatomy at Charing Cross Hospital Medical School

Dr Sloper received his medical education at Cambridge and the London Hospital After qualifying in 19[illegible] he held house appointments at the London He took the M R C P in 1946 and the M D Camb in 1951 He is at present senior lecturer in morbid anatomy at the London He has published papers on Addison's disease mycotic infections, and idiopathic diffuse muscular hypertrophy of the œsophagus

The title of professor of genetics has been conferred on Dr Hans Gruneberg, F R S, in respect of his post at University College

National University of Ireland

The degree of M D has been awarded to Edward O'Sullivan

University of Dublin

On Thursday, May 10, at 5 P M, at Trinity College, Dr Moacyr E Alvaro, president of the Pan American Congress of Ophthalmology, will deliver the Montgomery lecture, when his subject will be the Ætiology and Pathogeny of Uveitis Prof A St G Huggett will give the John Mallet Purser lecture on Thursday, May 24, at 4 30 P M, when he will speak on Environment of the Fœtus and Postnatal Health

Royal Society of Medicine

The gold medal of this society has been awarded to Sir Gordon Gordon Taylor

Empire Rheumatism Council

On Tuesday, May 1, at 2 45 P M the annual general meeting of this council is to be held at St James's Palace, London, when the Duke of Gloucester will preside

Medical Association for the Prevention of War

This association is holding a conference at 90, Buckingham Palace Road, London, S W 1, on Saturday, May 5, at 2 30 P M, on the Development of the Child in the Cold War Era

International College of Surgeons

This college has awarded its scholarship ($3000) to Mr W F Walker, of Dundee, who is to spend a year with Professor Moore, of Boston, working on surgical metabolic problems

Navy Medical Compassionate Fund

A meeting of the subscribers of this fund will be held at 2 30 P M on May 4 at the Medical Department of the Navy, Queen Anne's Mansions, St James's Park, London S W 1, to elect six directors

Royal Appointment

Surgeon Captain E B Pollard, R N, has been appointed an honorary surgeon to the Queen in succession to Surgeon Captain J V Williams, R N

New Medical Director of Navy

As announced last October Surgeon Vice Admiral R C May is to succeed Surgeon Vice Admiral Sir Alexander Ingleby Mackenzie as medical director general of the Navy Sir Alexander retires on April 30

Central Council for the Care of Cripples

The annual general meeting of this council will be held on Thursday, May 3, at 3 P M, at County Hall, London, S E 1, when Mr Iain Macleod, the Minister of Labour and National Service, will speak

Medical Exhibition

The organisers of the London Medical Exhibition are holding their regional exhibition this year in Cardiff from May 7 to 11

Queen Charlotte's Maternity Hospital, London

On Thursday, May 3, at 2 15 P M, a meeting will be held at this hospital, Goldhawk Road, W 6, to commemorate the 25th anniversary of the opening of the Bernhard Baron memorial research laboratories and the isolation block Dr Leonard Colebrook, F R S, and Mr G F Gibberd will speak

Chiropody for Old People

The National Corporation for the Care of Old People announce in their annual report for 1955 that they have set aside £60,000 to be spent over three years in making grants to voluntary organisations providing chiropody at reduced rates for needy old people

Course on Personnel Administration

The Ministry of Health announces (H M [56]34) that the Royal College of Nursing has arranged a course on this subject from June 4 to 15 Hospital authorities, especially those concerned with the management of mental or mental deficiency hospitals where staffing problems are acute, are asked to consider giving their matron or chief male nurse facilities to attend The fee for the course (25 guineas) would, it is suggested, be "a suitable use for non exchequer funds" Applications for membership should be made to the college, Henrietta Place, London, W 1

Appeal for a Students' Summer School

The London region of the British Medical Students' Association is organising a national clinical summer school to be held in London from Sept 2 to 16 This school will be attended by 50 students from all over the British Isles, and by 15 Yugoslavian students as part of a British Yugoslavian exchange scheme The students will pay their fares and £14 towards their accommodation, but further outlay will have to be met in arranging visits to hospitals and other institutions The association also hopes to help the Yugoslavians with their heavy travelling expenses Contributions should be sent to the hon secretary of the association, B M A House, Tavistock Square, London, W C 1 hat “glucocorticoid” eosinopenia can be produced in plenectomised individuals has convinced many workers hat the spleen plays no part in the production of this henomenon[28]

---

[1] How to Get Well Soon at Highwood Hospital Published by Brentwood Group Hospital Management Committee

That this conclusion may be an over simplification is hown by the observation of Kresbach and Sailer[29] who ioted that a significantly greater amount of corticorophin was required to give a positive Thorn test in plenectomised animals than in intact controls Similarly Sevitt, who compared the response in man of the blood eosinophils to corticotrophin before and 3–13 days after splenectomy, found that in some splenectomised patients an increase of the eosinophils preceded the corticosteroid eosinopenia, whereas in others the decrease in the eosinophils was greater than in normal controls Although, therefore, the spleen may not be essential for the production of eosinopenia—presumably other parts of the R E.S can compensate for its absence—it cannot at present be entirely excluded from the mechanism

---

Public Health

ATTENDANCE AT CHILD-WELFARE CENTRES

H D CHALKE
OBE, TD, MA, MRCP, DPH
MEDICAL OFFICER OF HEALTH, CAMBERWELL, DIVISIONAL MEDICAL OFFICER, L C C

THERE has lately been considerable discussion as to the present need for child-welfare centres Not surprisingly, there has been some divergence of view, ranging from the belief that the day of these clinics is done, or at least that their scope should be severely restricted, to the conviction that the advent of the National Health Service has in no way diminished their importance

While much of what has been said is speculative, many interesting facts have come to light as a result of interrogation of mothers by health visitors and by social workers

Miller (1952) and others found that in Newcastle the artisan classes patronised the centres most, and that “poor” mothers, whose need for guidance was greatest, were less liable to attend than “good” mothers only 1 mother in 5 attended regularly during a whole year

Fisher (1953) believes that mothers prefer the clinic to the surgery because they dislike troubling the busy family doctor

The survey conducted by George et al (1953) in Birmingham and Cosely, Staffs, led them to conclude that one of the reasons for the attendance of 44% of mothers was the ability to purchase there proprietary foods cheaply , it was suggested that, while there was still a place for the local-authority clinic, the medical officer might well be replaced by a general practitioner

Reed and Reed (1954) have called attention to the value of these clinics as a means of assuring mothers of children who attend for routine examination that their children are healthy Their records of consultations with clinic medical officers show that advice (chiefly on feeding and skin conditions) was given in 63% of cases and reassurance in 27%

Attention has been drawn to the fact that a large number of children attend the child welfare centre once or twice only In the Newcastle investigation (Spence et al 1954) it was found that only 50% of the children attended more than three times during the first year, and there was a fairly regular fall in attendances after each visit , Spence et al suggested that if the reasons for this fall could be found out, a great deal would be learned about what mothers needed, and how these needs could best be met

Although in many places there is evidence that the number of mothers making use of child-welfare clinics has slowly decreased since 1948, there has been little to suggest that their popularity has really waned very much (*Lancet* 1954) , indeed the introduction of a free general medical service has hitherto not had the notable effect that many expected If group practice becomes more popular, however, maternity and child-welfare clinics will be held increasingly in practitioners’ surgeries, and the municipal centre attendances will be undoubtedly affected , but the extent to which this will happen is highly uncertain

The Report of the Ministry of Health (part II), 1953, emphasises the educational and preventive character of the maternity and child-welfare service, which is not an extension of the outpatient department for sick children , the need for these centres, with their emphasis on education, remains undiminished The report points out, however, that there is much variation in the standard and method of health education, and that undue emphasis is often laid on the weighing of babies

The value of child-welfare centres as part of a preventive mental health service has lately received increasing attention , many believe that there are great possibilities here, but it must not be forgotten that work in connection with problem families and maladjusted children has long formed an important part of the activities of clinic doctors and health visitors (L C C Study Group 1954)

Questioning the public on health and other matters has become increasingly popular, and perhaps the answers given today lack some of the spontaneity and sincerity of those obtained when the public opinion poll was first introduced It may be objected that the replies given to general practitioners, health visitors, and social workers do not necessarily represent the true point of view of those questioned, but careful planning of questionnaires should in some measure offset this

Plan of Inquiry

I describe here the results of an inquiry in two boroughs in South East London, where, in addition to municipal clinics, many are organised by voluntary committees The aim was to discover the views of mothers on the value of child-welfare centres, and their reasons for attendance or non attendance

The inquiry was conducted in three parts

(1) A simple questionnaire was given to all mothers or adult females in charge of children visiting the centres during one week Sealed ballot-boxes were used

(2) In order to try to find out the attitude of mothers who did not make use of the municipal and voluntary clinics, a sample survey was taken in three new housing estates The interviewers were preclinical medical students (Guy’s Hospital) “Lead in” questions on health topics were included

(3) Mothers who brought their children to the clinics on a few occasions only were asked to give their reasons for the poor attendance They were sent a form which they were asked to complete and return to the health office

Findings

REPLIES BY THOSE ATTENDING CLINICS

1361 persons replied to the questionnaire To the first question—“what is the main advantage of attending a child welfare clinic ? ”—the majority replied both “check on progress” and “for expert advice” , 37 said that they came for companionship, 128 to relieve anxiety (table I) Surprisingly, only about 16% gave the ability to buy foods cheaply as one of their reasons, but there were distinct differences in the replies from those who attended different types of clinics In the voluntary centres, in which proprietary foods were available on a lavish scale and a Ministry of Food clerk attended, this reason was given by 24% of mothers , the figure was 6 7% in the

[28] Best W R, Muehrcke R C Kark R M *J clin Invest* 1951, 30, 629

[29] Kresbach E Sailer S *Klin Wschr* 1954 32 713

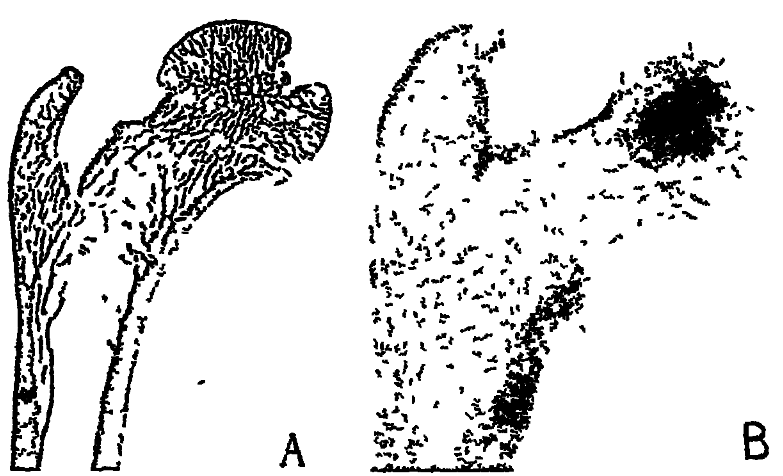

Fig 3—Radiographs of (A) section and (B) whole of femoral head of gorilla, showing *gravitational trabeculæ radiating towards whole surface of head*

degenerates earlier than that which is in current use during movement of the joint This view, which seems somewhat mechanical, is nevertheless essentially biological As a consequence of our more recent experiments we can suggest why the trabeculæ are shaped and reshaped and how they come to lie in the best position to carry the load of gravity and to bear other articular stresses

Organisation of Bone

In 1870 Julius Wolff described the ability of the spongiosa to orient its trabeculæ along the lines of force of mechanical tension and pressure That seems to have been the first expression of the relation between function and form in the living body His concept was confirmed by Roux (1885), and both Wolff and Roux established that pressure leads to the formation of bone This was contrary to the belief of von Volkmann (1862), who thought that pressure caused bone to atrophy Colmann (see von Meyer 1876), a mathematician, called medical attention to the similarity between the arrangement of the cancellous architecture of the femoral neck and that of a crane constructed on the principles of higher efficiency

However diverse the conclusions reached by many workers, there are some important points on which the majority agree, among them that the thickening of the cortical bone at the middle of the shaft corresponds to a region of danger, as happens in a bent beam at the point where the trajectories are closer to each other

Benninghoff (1927) found that osteone arrangement of the compact bone is a *continuation* of the trabeculæ of the cancellous bone A detailed study of the compact bone constituting the calcar femorale shows that this most dense of the cortical bones is formed by the pressing together of the great number of trabeculæ that come down from the head of the femur

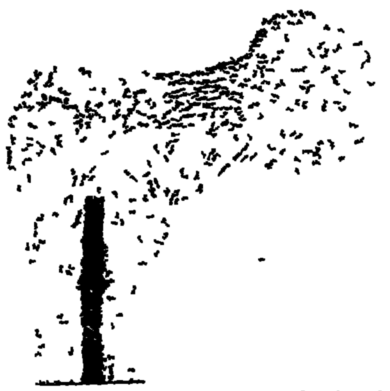

Fig 4—Radiograph of femoral head and neck of Neanderthal man (from O Walkhoff's "Studien über die Entwickelungsmechanik des Primatenskelettes," Wiesbaden 1904)

In 1920 Jores pointed out that the pressure is not always a stimulus but may be, on the contrary, often responsible for the reabsorption of bone He thought it was all a question of the amount and duration of pressure Scaglietti (1930) reported that an excess of pressure transmitted through the epiphyseal cartilage produces not a decrease in the thickening of the cartilage but an increase, together with a reduction in the growth rate No satisfactory reason had been given for the factors involved in this "inhibition"

It does not seem plausible to use in biology such terms as vulnerability, susceptability, inhibition, &c, all expressions that refer to, but do not explain, the real factors determining tissue behaviour In search of the explanation of this mysterious behaviour of bone and cartilage in transmitting the joint stresses, I made some experiments, at first with Mr J D Morgan and later with Dr A Trias, and the results are cited here

We already had evidence from cases of osteo arthritis that, when excessive pressure was transmitted through articular bone which was poorly protected, or totally unprotected, by cartilage, trabeculæ appeared with the central laminæ dead but surrounded by new living lamellæ We had suspected that, under the action of excessive pressure through the trabeculæ, the canalicular spaces by which the osteocytes are nourished were compressed and caused the death of the osteocytes even without requiring a miniature fracture of the trabeculæ The death of the trabeculæ seems to make an immediate appeal to the nearby vessels, which proliferate directly towards the dead laminæ and cover them by new lamellæ whose origin seems clearly vascular These findings seem to support Levander's (1938) hypothesis, which attributes to dead bone an osteogenetic action

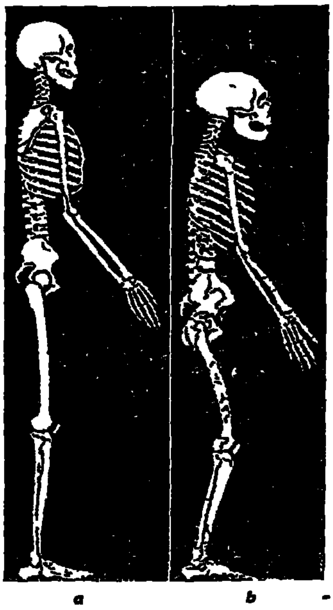

Fig 5—(*a*) Erect posture of modern man with hip and knee joints firmly locked in hyperextension, and (*b*) semiflexed position of both joints in primitive man

Changes Caused by Pressure

In our experiments on rabbits we used an apparatus based on Charnley's device for compression arthrodesis (fig 6) The knee of a growing rabbit was placed within the compressing frame, with one of its pins across the distal part of the femoral metaphysis and the other through the upper part of the tibial metaphysis As soon as it was noted that the animal tended to flex the knee to reduce the distance between the pins and thus the pressure across the knee a plaster slab or a complete plaster cast was added to prevent the leg from being moved In a few rabbits flexion took place at the joint either in spite of the splintage or because it had purposely

TABLE V—CRITICISMS BY 43 MOTHERS

Criticism	No
Risk of infection	16
Different views of people each week	4
Poor attention	4
Like to look after them myself	4
Long wait	3
Waste of time	3
Doctors rude	2
Never bothered	2
No faith in clinics	2
Interference	2
'Vague'	2
Do not agree with everything said	2
Not enough home visits	1
Prefer G P	1
Weighing only	1
'Too much messing about'	1
Did not get information required	1
Church hall too cold	1
No privacy	1
Ineffective	1
Put off by others	1
They want baby to grow up to their ideas	1
Some nurses better than others	1
Some nurses are poor advisers	1
Others	4

about frequency of attendance only 66% were prepared to say that the children had in fact been to the clinic

This is probably an underestimate of the true proportion since they were replying to a question to establish frequency of attendance, possibly a reply was withheld in some cases not because the children had never attended, but because the respondent was, in fact, uncertain of the frequency and did not care to say so

As might be expected, the frequency of stated attendance and the time since last attendance (asked only of those with children below school age) diverged, 20% said that they attend or attended weekly and, of those who gave a date for their last visit 14% said it was a regular visit made under a fortnight ago But whereas 67% said they attended monthly or more frequently, only 40% of those who gave a date for their last visit said it was a regular visit within the last six months It seems, therefore, that the stated frequencies of attendance must be regarded with some scepticism

TABLE VI—REASONS FOR DISCONTINUING ATTENDANCE

Reason	No
Too busy with other children	26
Child well, visit considered unnecessary	18
Attending own doctor	16
Indifference to child welfare	13
Mother ill	11
Mother at work grandparents looking after child	11
Distance to clinic too great	7
Too long a wait at clinic	5
Child ill	4
Satisfied with experience gained with older children	3
Unsatisfactory premises	3
Objection to advice given	2
Fear child might catch illness from other children	3
Child mentally retarded	1
Attends only to get help with child's clothing	1
Father a medical practitioner	1
Mother a nurse	1
Inconvenient day	1
Objection to referral to general practitioner	1
Fear and concern following death of first child	1
Did not want cheap foods	1
Difficult behaviour of older child at clinic	1

Criticisms, totalling 62, were made by 43 mothers out of a total of 306 questioned, 12 had never been to a clinic (table V)

REASONS FOR POOR ATTENDANCE

Scrutiny of the registers at eleven child welfare centres, selected at random, showed that in 1953 there were 2826 new attendances Of these 248 came on three occasions or less 145 (5%) once only and 103 (3 6%) came two or three times 58 had left the district 14 were attending other child-welfare centres, and 6 were in day nurseries

The remaining 170 children (6% of all first attenders) were followed up by writing to the mothers and asking them to state in confidence their reasons for not continuing to attend The replies (131) are classified in table VI In 72 cases the reason for ceasing to attend may have been unavoidable (inability of mother to attend, or child ill or under care of general practitioner) and in 59 cases the reason was avoidable (mother did not consider further visits necessary, 38 criticism of premises or advice 21)

The most significant point that emerges is the belief among a large number of mothers that, after the first baby, clinic attendance is not worth while unless the child is not making progress Evidently, also as the family increases in size, greater difficulty is experienced in finding time to visit It is surprising that there were so few valid criticisms of the clinic premises or the attention received Those who objected to the waiting-time were found on investigation to have grounds for complaint, but where the long distance to be travelled to the clinic was mentioned the complainants in no case lived more than a mile away The infrequency with which the general practitioner was mentioned was unexpected, in 1 case the reason given for ceasing attendance was an objection to the child being referred to the family doctor Needless to say the complaints made by mothers have all been followed up by the health visitors attached to the clinics concerned, and the complainants visited These visits have confirmed the view that the majority of the criticisms had little foundation, but they have demonstrated the need for keeping in touch with those who do not attend regularly or cease attendance

Conclusions

A large majority of mothers favour attendance at child-welfare clinics, because these provide a means of obtaining expert advice, checking progress, and relieving anxiety It is apparent, however that a large number do not think it necessary to visit if the child is making favourable progress, particularly in the case of subsequent children Many mothers feel that the knowledge gained (generally at the clinic) with the first child, equips them to deal adequately with those that follow Moreover the difficulties experienced in attending increase with the size of the family

Ability to purchase welfare foods was not as significant a reason for attendances as might have been expected It was found that at clinics where Ministry of Food preparations could be bought there had been very little increase in the number of clinic attendances Weighing was not mentioned to any great extent, and treatment (and this is gratifying) not at all The family doctor seldom figured in the replies, and preferences for the clinic or the surgery were fairly evenly balanced Risk of infection was mentioned only by respondents who were questioned at home, and nearly half of these had never attended

Those who frankly disbelieved in municipal clinics did not often give valid reasons in support of their objections, and criticisms even from unbelievers were few Those relating to the staff or premises were found on investigation to have foundation in some cases, and for this reason, if for no other, the inquiry had some value It also showed how essential it is for the health visitor to follow up all cases in which attendance ceases It is a matter for surprise—and conjecture—that criticisms of premises were so infrequent, for many of these are far from satisfactory Although most of the women claimed that they were regular attenders, there is a good deal of doubt as to whether this was a fact

The demand for child-welfare clinics is as great as ever, but their value in the promotion and maintenance of health is insufficiently appreciated For this the atmosphere of the clinic, if it has not changed with the trabeculæ leading to (*c*) a typical bone cyst under (*d*) degenerated disintegrating articular cartilage

Injected specimens show that no vessel of any importance penetrates the centre of the cyst (fig 10) If instead of killing the rabbit while the pressure was still being exerted, the pressure was removed and the rabbit was allowed to survive for a few days, regeneration of the ischæmic area by new vessels was immediate As supporting evidence we may add the sudden transformation of the hypertrophic growth cartilage in bone together with the invasion of the cyst by newly formed vessels (fig 11), showing the great tendency to heal of all these damaged tissues once the compression has been removed

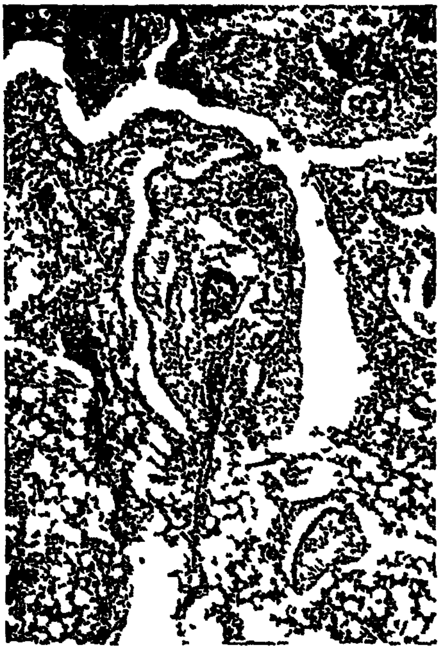

Fig 11—Four days after removal of sustained pressure revascularisation of "cyst" has already begun

The area of maximum pressure in the direction indicated by the changes of the articular and epiphyseal cartilages shows numerous trabeculæ whose central lamellæ are dead or dying, surrounded by new laminæ which in well injected preparations show intimate connection with vessels (fig 12) Some of the areas of bone condensation, such as those surrounding a bone cyst, exhibit this necrotic or dying core buried under the strata of new lamellar bone Thus experimentally the bone changes caused by ischæmia seem to stimulate the formation of bone through the mediation of vascular proliferation, this we had already suspected to be the case in human osteo arthritis Similarly, the consequence of interfering with the flow of fluid through an articular cartilage submitted to exercise and constant pressure will cause its final disintegration and, with it, the direct transmission to the underlying bone of all the evils of the crushing pressure

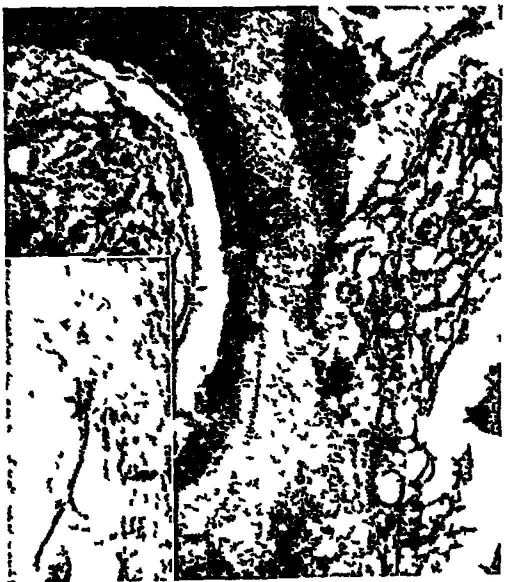

Fig 12—Dead or dying trabeculæ surrounded by new lamellæ of vascular origin Inset newly formed vessel adherent to old trabeculæ

Ischæmia as Cause of Reshaping of Trabeculæ

We tried to discover the mechanism by which the trabeculæ in the spongiosa and the osteones in the cortical bone are oriented, and our conclusion is that the whole process is guided by the intimate relationship between tissue pressures and the flow of blood and other fluids As long ago as 1905 Gerbhardt had the intuition that the architecture of bone is largely determined by the vascular system Later, in 1923, Weidenreich noticed that the lamellæ of cancellous bone are always placed round spaces containing vessels and follow their direction, he also believed in the importance of pressure in determining growth or atrophy of bone

In our research on osteo arthritis we repeatedly found suggestive evidence of the mechanism by which the trabeculæ most submitted to pressure—e g, those that carry the load of gravitation—become hypertrophied The increase in the load may be felt by the trabeculæ in three different ways (1) by increase in the weight borne by them, (2) by reduction of the area or space through which the weight is borne, and (3) by increased duration of the load The product of the weight and its duration, divided by the space $\frac{(W \times T)}{S}$ will indicate the amount of gravitational stress transmitted through the joint Other factors, well studied by Pauwels (1952), ought to be considered—e g, the distance of the great trochanter to the femoral head and to the mid pelvic line, the shorter the distance the greater being the stress To this I would add the crushing stress of locking the hip-joint in hyperextension this submits the femoral head to pressures similar to that exerted by a pair of pliers in cracking a nut

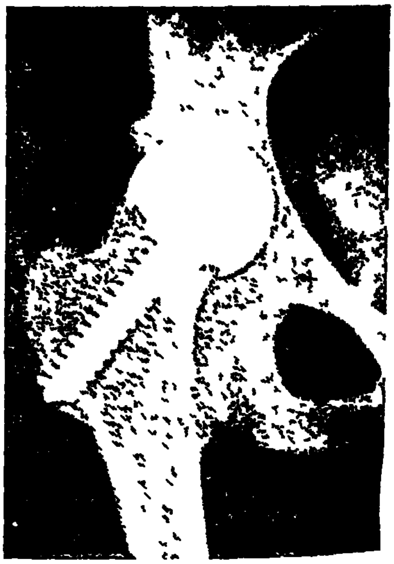

Fig 13—Hip arthroplasty aiming at better distribution of stresses between metallic prosthesis and surrounding bone

In the present experiments we studied not the earlier changes in the joint cartilage which we had found to be located in the non-weight bearing area but the results of excessive tissue pressure which, in man, is caused by the combined action of the gravitational and muscular stresses Degeneration of the articular cartilage causes the subchondral vascular proliferation which, penetrating the cartilage, abolishes its resilience by forming the osteophyte and causes pain Pain limits movement of the joint, thus a more reduced area of the head of the femur and the acetabulum now support the weight for much longer Muscular spasm joins with the other deleterious factors which end by destroying the joint

In England Now

A Running Commentary by Peripatetic Correspondents

In the book of elves and fairies beloved in my childhood, mental deficiency looked different from the problem which now I face.

The beautiful baby became a changeling—presumably through kernicterus or tuberculous meningitis—and lay brown, shrunken, and screaming in his cot till the goblins bore him back to fairyland. Nowadays the goblins' theft is often prevented by the cabbalistic rites of blood replacement or intrathecal antibiotics, and the changeling remains, failing to gain weight, demanding and angry, dancing with rage because Earth has denied it honeydew.

In the Irish myths the plump, slow, creamy girls, or lads, with the eastern eyes were once the "lucky ones" who had either been blessed by the saints or had strayed as two-year olds into the fairy ring, led by their slanting eyes and their "luck" into lonely adventures denied to others. They were laughed at, slow to learn, and loved music; they blundered but were tolerated. They too "joined the fairies" in childhood as did our own mongols before antibiotics were discovered.

Others, who had been left in a fairy ring by a careless sister or brother in infancy, were less lucky, for they could ermore escape its ceaseless dances. Charms were of no ul, nor even holy water, though sometimes a wise man ided their dance into useful ways, as we do with our astics.

The book of elves and fairies led me astray, or the aries have cursed the age of hydrogen. These are no onger the lucky ones. Today the changelings survive to rage and scream their way through the shrill echoing memories of their siblings. Mongols are no longer "blessed", their childhood is not guarded by a spell nor their musical gifts used. The wicked fairy Pædiatrica stands by the cradle, and removes the normal spell of motherhood. "You have borne a monster—a mongol—hide it from the sight of other children lest they be afraid." I wouldn't mind this so much if Pædiatrica would wave her wand until the long waiting-list for mental-deficiency institutions had vanished. Instead, like all wicked fairies, she disappears immediately in a puff of smoke, pocketing a domiciliary fee, or pontificating to the apprentices.

I wish you would go away, or stop your charms, Pædiatrica, and, pending more green hills for changelings, give the peculiar-looking baby a chance to turn out "lucky" at home.

* * *

A Cockaignshire local medical committee has been earing an interesting case. Dr X, a local practitioner, as asked why he had prescribed, on an E.C. 10, a stone of dog-biscuits.

Dr X explained that the patient, Mr Y, believed himself to be a dog, and was under the care of a Psychiatrist who insisted that he be humoured and prescribed certain tablets. The only way to get Mr Y to take the tablets was to conceal them inside small dog biscuits. Dr X contended that the dog-biscuits were therefore not a food, but an ancillary medicament or vehicle, the equivalent of a syrup or flavoured water. If the Chairman thought he could talk Mr Y out of his delusion (said Dr X), he was welcome to try; but so far Mr Y had proved unusually intransigent. Indeed, after his last session with Mr Y, the Psychiatrist had suddenly tied a small barrel under his chin and crawled out howling into a snowstorm.

Dr X claimed that his duty not only as a doctor but also as a citizen demanded that the patient be kept fit for work; for Mr Y was a key man. He made the tea for the men who made the tea at the Ministry of Incoördination in Ataxia House. He was irreplaceable also in that he was left handed, and nobody else could use his peculiar left handed teaspoons. The Committee would be aware from the Press (continued Dr X) that there was a crisis over the question of pay differentials between right and left handed tea stirrers, and he would ask the Chairman whether the national economy was to be endangered for the price of a stone of dog biscuits.

Dr X spoke for a further 45 minutes on the Englishman's love of animals, concluding by singing several verses of a ballad entitled, *My Four-legged Friend*, and inviting the Committee to join in the choruses. But the meeting had to adjourn, owing to the indisposition of the Chairman, who felt his nose becoming hot and dry.

* * *

The last patient at the clinic was a woman with neurodermatitis. The boss was evidently tired. He had reached the critical point at the end of the afternoon when his mind would accept nothing but the most relevant remark through its fatigue barrier.

"Now ma'am, you have had your skin trouble for how long?"

"For thirty years at least. I have seen most of the dermatologists in the country, and none have done me any good."

"And what makes you think we will succeed where they have failed?"

"I had heard you were supposed to be good at this sort of thing."

The boss closed his eyes and breathed deeply. Anyone who did not know him would think he had fallen asleep. I knew he was wrestling with his serpent.

"Tell me, ma'am, do you use nail varnish?"

"It seems rather a personal question, but if it is of any interest to you, I don't. My nails are naturally highly polished."

"Naturally. And do you scratch?"

"Never! Dr Smyth accused me of that. It simply isn't true. I want to scratch but I am able to control myself."

"Indeed. How long have you had your eczema?"

"Is that what it is! Then why do they call it dermatitis? every specialist that I come to has a different name for it. I do wish someone would explain to me in simple language what I have got and how to cure it."

The boss turned slowly on his swivel chair and addressed me as though we were alone together.

"Not so easy, Peter. How does one explain in simple language that this skin lesion is a localised area of unhappiness, a focus of frustration? It is a flag she is waving, but whether for help or in warning it is difficult to decide. This patch of eczema is a target on which she receives the slings and arrows of outrageous fortune; though, here again, if fortune is outrageous we are so often ourselves the cause of it being so. And she has, of course, scratched and scratched and scratched continuously for thirty years to sustain it."

"Do you mean to tell me that I have deliberately kept it going? It's ridiculous!"

" to sustain it for fear of losing it."

"Well, it is obvious that I am not going to get any help from you! It was a waste of time coming."

His voice lost its edge and I knew the physician had begun to rewind the serpent round its staff.

"Sit down, dear lady, and relax a little. I am sure we can help you. We will give you a paste and the rash will improve if you don't scratch. I shall also dispense for you some medicine."

"I have heard that before. Is it brown? I've had it! It never did me any good—only upset my stomach!"

"I shall dispense some bromide and nux vomica. This is *not* brown but red like claret."

The boss took my arm and led me out of the cubicle.

"Peter, I would like to see this patient again in six weeks, when I hope to prove to you that there are some skins that we have no right to cure if we have the comfort and happiness of our patients at heart."

I took a swift look to see if he was smiling. If he did smile it had already gone; but he did not look quite so tired.

* * *

News from School.—The music comp. was very good. The pianos were never together. Even the recorders were not together, let alone being in time with the pianos. Everybody was stifling their laughter.—House had cellos, violins, and viola, but people say it was not a match against last year's, as it was not nearly so out of tune.

TABLE I—SURVIVAL OF BACTERIA IN BROTH CONTAINING 16 µG CHLORAMPHENICOL PER ML

Species	Days of incubation					
	0	1	2	3	5	7
Strep. fæcalis	400	500	400	300	500	400
Strep. pyogenes	200	0	0			
Staph. pyogenes	400	250	100	35	3	0
S. typhi	500	200	65	3	0	
S. paratyphi B	1000	400	200	12	0	
Esch. coli	1000	100	9	0	0	

Note. The numbers show the number of colonies growing from a drop (c. 0.03 ml.) spread on agar.

indication of the course of events. When the broth appeared to be sterile, its sterility was often confirmed by centrifuging and resuspending a larger sample in fresh medium. The lag period in the subcultures was often prolonged in the later stages of a test, so that two or more days' incubation was needed. Subcultures on blood agar plates were found to be more reliable than those on nutrient agar, even with freely growing species.

4. The tests reported here were made with chloramphenicol which has the advantages of a wide spectrum, stability for more than two weeks in the incubator, and a reasonable level in the cerebrospinal fluid (a third to a half of that in the blood). Erythromycin seemed to be nearly as stable, but tetracycline was largely inactivated after five days. It has been assumed that blood levels of 16–32 µg chloramphenicol per ml. are readily obtained, corresponding to 5–10 µg in the cerebrospinal fluid, and that higher levels can be expected with heavy dosage. Most of the tests have therefore been made with concentrations of 16–25 µg., but the effect of 5 and 10 µg has also been observed with strains of meningococcus, pneumococcus, and *H. influenzæ* in view of their association with acute meningitis. In addition a few individual strains have been tested over a wider range of concentrations.

5. The majority of the strains were isolated from specimens sent to the London Hospital Clinical Laboratory. With some species (e.g., of salmonella and brucella) only laboratory cultures were available. It is realised that as many strains as possible should be tested, but it is hoped that enough has been done to show that species vary considerably in their ability to survive.

6. The inoculum used at first was such that the sample drop, spread as soon as the test was set up, yielded 1–500 colonies—a number which could be counted or estimated with reasonable accuracy. In later tests the inoculum has often been much increased with organisms which tend to die out rapidly.

Results

Table I is shown as an example of an experiment in which five strains of different species were exposed to a concentration of 16 µg chloramphenicol per ml. in broth. The first column shows the days on which subcultures were made, those on "Day 0" being taken as soon as the test was set up. The figures indicate, in round numbers, the number of colonies observed. It is possible that the variations with *Strep. fæcalis* are largely due to faulty estimation; but, even as shown, the ability of some strains of this species to persist under conditions of bacteriostasis is remarkable considering that none of the others survived for as long as a week, *Strep. pyogenes* failing in this case even to survive for a day.

Table II indicates the general results obtained with the various species, listed according to their tendency to die out rapidly. The susceptibility of the neisseria was to be expected from the clinical reports. The strains of *H. influenzæ* and pneumococcus were derived (except a pneumococcus type I) from routine cultures. All these strains were respiratory in origin with the exception of two *H. influenzæ* from the meninges, one type b and the other type f from an unusual case in an adult. The latter strain to some extent "spoiled" the figures for the species, being somewhat more persistent and less sensitive than most of the others. In general it seemed clear that in both species there were minor variations in susceptibility, and that a concentration of 10 µg chloramphenicol per ml. was necessary to ensure either sterilisation, or a near approach to it, within two days. The brief survival of the two laboratory strains of *Corynebacterium diphtheriæ* is interesting in the light of Forbes's (1954) report that erythromycin, a bacteriostatic drug, was more effective than the bactericidal penicillin in clearing up carriers.

Mention must be made here of an untoward finding observed once with the type-f hæmophilus in 5 µg chloramphenicol per ml. and once with a pneumococcus in 10 µg. Subcultures yielded a few colonies over a period of a week or more, the companion bottle in each case (and also two pneumococcal bottles with half the concentration of drug) becoming sterile much sooner. Examination of films suggested that the persistence was due to agglutination of the bacteria by antibody which chanced to be present in the blood.

Strep. pyogenes was not tested with the idea that penicillin might be supplanted by chloramphenicol in the treatment of acute streptococcal infection but in order to estimate the probable effect of a bacteriostatic drug on the carrier state, which often resists short courses of penicillin. The results suggest that this species would respond less rapidly than *C. diphtheriæ*, especially since in the carrier the presence of specific antibody would favour agglutination of the cocci.

The response of the staphylococcus, even in broth, is relatively slow; and, especially when the staphylococcus is clumped in blood broth, it is sometimes, though not always, indefinitely prolonged, positive subcultures sometimes persisting in the fourth week although frank multiplication is still controlled. These conditions may well reflect those in generalised staphylococcal infection, in which treatment, even with penicillin, against a sensitive strain must be prolonged in order to prevent recurrence derived from "persisters" in small abscesses.

Like the staphylococcus, the typhoid bacillus sometimes persisted in blood broth but sometimes died out in about a week. In the former case films once again suggested that agglutination of the bacilli into small clumps was responsible. In the human body, however, the bacillus probably multiplies to some extent within the host cells—a situation difficult to simulate in vitro. Similar results were observed in a few tests with *Salmonella paratyphi B* and *Escherichia coli*.

Although relapse is common in brucellosis after treatment with the bacteriostatic drugs, the use of blood

TABLE II—SURVIVAL OF BACTERIAL SPECIES IN PRESENCE OF CHLORAMPHENICOL

Species	Number of strains	Concentration of drug (µg per ml.)	Medium	Original number of colonies per drop (average)	Result	
					Days of incubation	% surviving
Gonococcus	1	8 or 4	B.B. (boiled)	89 × 100	1	0
Meningococcus	1	10 or 5 2.5	B.B.	50 × 10³ "	2 3	0 0
H. influenzæ	10 7 7	16–20 8–10 4–5	" " 	100 × 10³	1 2 2	0–<0.1 0–0.1 0–1.0

Notes. Size of drop: 0.02 ml. (approx.).
Colony count: 100 × 10³ = 100 colonies grow from spread of drop after 1:1000 dilution.
B.B. = 20% horse blood broth.
*Staphylococci occasionally persist longer.

still coronary disease is relatively uncommon in these populations Finally, there is no evidence that race is involved and a good deal of evidence that it is not, notably in comparisons between Negroes in Africa and in Chicago, in comparisons between people in the same region who differ in their economic circumstances (as found in our studies in Spain and in Italy), and in our current comparisons between Japanese in Hawaii and here in Kyushu But in all of these situations attention to the total fat in the diet seems to bring an orderly relationship into focus

Probably no such clear and simple relationship would be found if the dietary predilections of the world's populations for quantities and kinds of fats varied independently I should not expect to find the same serum cholesterol levels and frequencies of coronary heart disease in two populations both getting 40% of their calories from fats but the one deriving this from corn oil and sesame seed oil while the other got all their fats from coconut oil and lard But this does not happen to be the way people consume fats In a desperately poor land the people get very few fats of any kind As their lot improves economically they increase their total fat consumption, *and* the fats they eat tend to be more and more the more expensive kinds—the fats that, incidentally, are associated with the foods most highly prized for their nutritional as well as their gustatory value

To some of us, at least, it appears that this response to prosperity can go too far The problem has been complicated by the enterprise and ingenuity of food producers and technologists who provide a superabundance of all kinds of fats and then persuade us to eat them Are we now going to ask them, please, to put some more E F A in their wares ? Perhaps with a modest increase in cost ? This could be the shape of things to come Continue, or increase, your high fat consumption but be sure you get a lot of corn oil, sesame seed oil, fish oil, and the like and be careful to swallow it fresh and in the virgin liquid state !

Such considerations may seem inappropriate in a discussion of a problem that is basically chemical and pathological But the coronary problem has already reached dimensions that cannot be confined in the otherworldly atmosphere of some academic retreats In the meantime, it is clear that a great deal more research is needed on all aspects of the problem, including food economics and the psychology of food preferences While this is in course it may be well to ponder whether a diet containing 40% of its calories as fats is really essential for human happiness and, if not, how may it best be reduced

ANCEL KEYS

VOMITING SICKNESS IN JAMAICA

SIR,—There are two important points which might be added to your leading article (April 14) As far as I know, chemical analysis has not yet been published to indicate in what part of the ackee fruit the toxins are found If they are only in the seed, then the population can continue to eat the arillus with impunity Children who eat the seed in play, or tragically driven by hunger, must be more carefully supervised The other point is quantitative not only which part, but how much of which part, of the fruit is likely to produce a toxic effect

The full report of the work done in 1952–53 (excepting the chemical section) was published by the Government Printers, Kingston, Jamaica, in 1954, as a monograph on Vomiting Sickness in Jamaica

CICELY D WILLIAMS

REVISION OF THE CURRICULUM

SIR,—The only positive contribution in the proposals of the Royal College of Physicians anent revision of the medical curriculum is the suggestion that the G M C should cease to issue recommendations—in other words, abrogate its function as guide and supervisor of the training of medical students Otherwise the report (of which extracts appeared in your issue of April 14) consists in the usual ponderous, pontifical pronouncements that the aim of medical education should be to give "a broad cultural background," "the acquisition of a scientific attitude," "principles and outlines without the burden of fact," &c , &c We have heard most of it before in the perennial bellyache about the medical curriculum which is a perpetual item on the agenda of committees of medical schools and Royal colleges and corporations, in fact of every conceivable body except those best suited to advise—namely, the general practitioner No other training schemes—for lawyers, engineers, scientists, &c —are subjected to so much interminable "research ". Quite obviously the present training of the medical student is unsatisfactory, uneconomic, and much of it wholly irrelevant to the work subsequently undertaken by the great proportion of medical graduates

Medicine is not a philosophy nor is it a science It is a skill, much of it still empirical , and, like training for any other skilled job, the education of the medical student should include, from an early stage, a concurrent and remunerated apprenticeship The people want a doctor who knows his job—who can, for example, recognise scabies when he sees it and tell them how to treat it They are not particularly concerned whether he can discourse on Scabies in Mediæval Times or The Adaptive Mutations from which Evolved the Behaviour Pattern of *Acarus scabiei*

Would it be wrong to suspect that given freedom from G M C recommendations a "model" curriculum would emanate from the Royal College of Physicians, which might even be prepared to send its representatives to the various medical schools to initiate the new era ?

Department of Anatomy,
University of Glasgow

GEORGE M WYBURN

SIR,—The very interesting report by the Royal College of Physicians, prompts me to ventilate an idea which might possibly be applicable as an experiment at one, say, of our "red brick" universities

It is, in effect, the introduction of a tutorial system, whereby each of the younger clinicians attached to the medical school would act as tutor to some five or six students for the whole of their undergraduate life They would meet him perhaps for two one hour sessions each week, on one occasion to discuss an essay he had set, and on the other for a general round-table conference The value to the students would be obvious in bringing them from the first into personal contact with an active practitioner of their craft and would give them an initiation, particularly when they reached their clinical years, to the real as distinct from the textbook problems of medical work The value to the tutor would hardly be less, since it would necessarily keep him up to date not only with other branches besides his own specialty but with his anatomical, physiological, and psychological knowledge

One of the dangers of the age of specialism is that, while knowledge in a particular field may become ever more detailed and exact, the specialist is liable to fall behind even the newly qualified graduate where the rest of the subject is concerned , and my scheme would very effectively prevent this, since it would be useless to try and talk to a critical audience without an adequate familiarity with the matters under discussion

Darlington

JOSEPH V WALKER
Medical Officer of Health

one but significant from the clinical aspect, as the work of Cates, Christie, and Garrod (1951) has shown chlortetracycline and chloramphenicol were useless in the treatment of endocarditis due to infection with *Strep fæcalis*

It may also be argued that the action of a drug varies, being bacteriostatic for one bacterial species but bactericidal for another Biochemical studies on the effect of chloramphenicol on the assimilation of amino acids by bacteria, as reviewed by Gale (1953), were mainly concerned with the staphylococcus, in which the over all action is on protein synthesis, but they give no suggestion of an alternative effect likely to bring about the rapid death of, for example, the pneumococcus Further it should be noted that the species which seem to be most susceptible to the action of the drug are those which need frequent subculture, at least on simple media

Jawetz and Gunnison (1953) question the description of drugs as bacteriostatic or bactericidal Including penicillin in their argument, they state that, as the concentration of the drug rises, after a possible zone of stimulation, the growth of bacteria is inhibited before the lethal concentrations are reached Admittedly at one stage the number of survivors must remain constant for a time, but this does not imply inhibition in the true sense of the word The typical action of penicillin (see Florey et al 1949) is maximal when the bacteria, in the absence of the drug, would be multiplying freely Hence one may reasonably suppose that when the effect of penicillin is partial (because its concentration is low) its action on the individual bacterium is either bactericidal or ineffective—never being truly bacteriostatic It is true that at much higher concentrations—unattainable, or not normally attained, in systemic treatment—the actions of some of the antibiotics may perhaps be reversed, but for practical purposes the use of the two descriptive adjectives seems to be justified

Summary

Sensitive strains of various bacterial species have been tested for their ability to survive under conditions of bacteriostasis caused by adding chloramphenicol to the culture media This drug was chosen for technical reasons, but the effect of other bacteriostatic drugs on sensitive bacteria is probably similar

Tests were carried out both in simple media, such as nutrient or digest broth, and in 20% horse blood broth (The horse leucocytes appear to survive refrigeration for a week or more and incubation for a day or so) Subcultures from the blood broth tended to remain positive longer than those from simpler media—perhaps because the bacteria were preserved by agglutination or clumping

It seemed that, in relation to bacteriostasis, bacterial species might be regarded as

1 *Highly susceptible* —Gonococcus, meningococcus, *Hæmophilus influenzæ*, pneumococcus, *Corynebacterium diphtheriæ*
2 *Moderately susceptible* —*Streptococcus pyogenes*, *Staphylococcus pyogenes*, the coli typhoid group, *Hæmophilus pertussis*, and some strains of *Strep viridans* isolated from cases of endocarditis
3 *Insusceptible* (in practice) —*Strep fæcalis*

These findings are briefly discussed

My thanks are due to Prof C F Barwell, and other members of his staff, for advice, and to the staff of the Clinical Laboratory, under Dr H B May, for the supply of bacterial strains isolated during their routine work

THROMBOTIC MICROANGIOPATHY

HISTOLOGICAL DIAGNOSIS DURING LIFE

W St C Symmers
M D Belf, Ph D Birm, M R C P
PROFESSOR OF MORBID ANATOMY IN THE UNIVERSITY OF LONDON AT CHARING CROSS HOSPITAL MEDICAL SCHOOL

Thrombotic microangiopathy (thrombotic thrombocytopenic purpura) is a well-established entity Including Moschcowitz's (1924, 1925) original case and the 3 described here, at least 85 indisputable cases have been recorded (*59 from the United States, 15 from Britain*, and others from Cuba, Czechoslovakia, Finland, Germany, Hungary, Italy, and Switzerland) In addition, I know of over 30 unpublished cases, most of which I have seen through the kindness of colleagues in Britain and oversea Only 35 of the 85 published cases had been reported by the end of 1951 of the 35 all but 3 British cases (Pagel 1949 [case 4—see Symmers 1952], Symmers and Barrowcliff 1951, Symmers and Gillett 1951) were from the United States, whereas 23 of the 50 more recent cases were reported from other countries Of these 50 cases 17 were diagnosed during life, in contrast with only 4 of the 35 earlier cases These figures reflect a greater awareness of the features of thrombotic microangiopathy, enabling it to be recognised oftener, both during life and post mortem

Clinical Diagnosis

The clinical diagnosis is usually suggested by the development of a characteristic tetrad acute febrile illness, hæmolytic anæmia, thrombocytopenic purpura, and neurological disturbances In most cases this syndrome develops fully only late in the comparatively short course of the illness, and the diagnosis is seldom made until very shortly before death If thrombotic microangiopathy is to be recognised early, the clinician must consider it in the differential diagnosis of every illness presenting with any of the components of the tetrad

Biopsy

At present, only biopsy offers any hope of providing irrefutable confirmatory evidence of the diagnosis, it has so far played only an insignificant part

Excluding the cases reported in this paper, biopsy was done in only 7 of the other 19 published cases which were diagnosed during life, and the result was positive in only 3 The lack of information from biopsies is due partly to the infrequency of the lesions in the vessels of the tissues which are usually chosen (skin and muscle), and partly to patients usually being too ill to undergo biopsy at the late stage when the diagnosis is ordinarily suspected

Altschule (1942) was the first to suggest that thrombotic microangiopathy could be recognised in life, and the possibility that biopsy might aid diagnosis was first mentioned by Bernheim (1943)

The first 4 cases to be correctly diagnosed clinically were reported by Engel et al 1947, Epstein et al 1948, Singer et al 1950, and Meacham et al 1951 Biopsy was first done following clinical diagnosis in a case reported by Blackman et al (1952), the first positive biopsy was recorded by Chediak et al (1952)

Several workers since Bernheim (1943) have advocated biopsy in the hope that early diagnosis might help investigation of the nature and treatment of thrombotic microangiopathy

Choice of Tissue

At necropsy, evidence of thrombotic microangiopathy has been sought in tissues accessible to biopsy, and these studies have shown considerable variation between cases for instance, there may be many lesions in skin and skeletal muscle, but oftener the vessels in these tissues are not involved

It is obvious, therefore, that both our results are in the sest possible accord and that together they supply nvincing evidence that the abnormality in myasthenia an alteration in the response of the motor end-plate acetylcholine

PARATYPHOID-C OSTEOMYELITIS

SIR,—In their article of April 7 Dr White and Dr eynell review the reported cases of osteomyelitis due to lmonella and indicate the rarity of this condition, rticularly in salmonella infections other than *Salmonella phi* and *Salm paratyphi B* The following recent case osteomyelitis of the parietal bone due to *Salm dublin* ay therefore be of interest

A woman, aged 72, was admitted to hospital, under the re of Dr C W Walker, with severe anæmia On examina on she was confused and had early heart failure and right asal pneumonia A swelling was present over the left parietal one A blood count showed Hb 37%, packed cell volume 0%, mean corpuscular hæmoglobin concentration 27 5%, nd white cells 10,000 per c mm, with a pronounced shift to ne left Radiographs of the skull suggested a vascular tumour n the parietal bone The presumptive diagnosis of secondary arcinomatosis from an unknown primary was made The atient's condition initially improved with blood transfusion nd penicillin Her condition then gradually deteriorated and he died on March 23 On retrospective inquiry it was iscovered that the patient had had mild diarrhœa in the ospital

At necropsy the parietal bone was found to be eroded and here was a collection of pus in the adjacent subaponeurotic nd epidural spaces, cultures of which yielded a profuse growth f *Escherichia coli*, *Clostridium welchii*, and *Salm dublin* *alm dublin* was also found in cultures from the intestine

On histological examination the parietal bone showed hronic granulomatous osteomyelitis with a predominance of mononuclear phagocytes, as in a typhoid lesion Similar ranulomatous lesions were present elsewhere in the body ections of the sternum, however, showed infiltration with arcinoma cells

On later inquiry it was learnt that the patient had ived on a smallholding where losses from calf diarrhœa—a condition frequently associated with *Salm dublin* nfection—had been a feature

It seems probable that the course of this patient's infection with *Salm dublin*—an organism which only rarely causes a systemic infection in man—was influenced by a lowered state of resistance due to the concurrent carcinoma

D R CHRISTIE
County Hospital, Hereford — K VALTERIS

ANTENATAL DETECTION OF HEREDITARY DISORDERS

SIR,—The recent articles on a technique for determining the ABO blood group from epithelial cells[1] and confirmation[2] of the recognition of sex from epithelial cells from the amniotic fluid[3] have opened up the possibility of a new field of preventive medicine

It should eventually be possible for most prospective parents with inherited disorders transmitted by single genes to obtain a fairly precise estimate of the likelihood of their coming child being affected by the twelfth week of pregnancy,[3 4] when termination would be simple and would not impair subsequent fertility About half such pregnancies would be affected, and their interruption would probably not reduce the number of live births finally achieved by most parents At present such terminations would be illegal, except possibly in incipient erythroblastosis fœtalis

In sex-linked recessive disorders, such as hæmophilia, the interruption of girl-bearing pregnancies would eliminate transmission through known cases

The reduction in the transmission-rate of disorders determined by autosomal dominant genes requires knowledge of their linkage with genes determining the observable behaviour of the amniotic cells One such linkage with the ABO system has recently been described[5] The development of methods of recognising genetically determined attributes of such cells and an increased knowledge of linkage in man, should enable a great reduction to be achieved in the transmission of such diseases as Huntington's chorea, polyposis coli, arachnodactyly, and acholuric jaundice, without acting against the desires of the majority of afflicted persons

The prospect of such preventive measures, and of relevant legislation, is particularly important in that not only are environmental improvements allowing increased proportions of afflicted infants to mature, but the increasing exposure to X rays, atomic piles, and experimental war will inevitably increase the mutation-rate in man

London N 1 — J H EDWARDS

PERFORATED ACUTE AND CHRONIC PEPTIC ULCER

SIR,—I would like to support Mr Hermon Taylor and Mr Warren (April 14) in their opinion that not all perforated peptic ulcers should be treated in the same way, and agree with their treatment policy as far as it goes, having arrived at the same conclusions for other reasons[6]

I say "as far as it goes," for no less than 7 patients out of 93 were considered to be moribund on admission and their deaths inevitable, no details are given of these patients As I pointed out in my paper, patients who are gravely ill from the peritoneal effects of a perforated ulcer will all die if treated by aspiration, but some will recover if the peritoneum is cleared of free fluid at operation and vigorous resuscitation is applied, and reinforced by noradrenaline if there is no response to the usual methods

Exeter — H DENDY MOORE

RECURRENT DISLOCATION OF THE SHOULDER

SIR,—I might have overlooked the specious simplicity of your leader (April 14) had it not cast a reflection on the activities of that hard-worked branch of the profession—the orthopædic surgeon, imputing to him slackness in investigating an apparently simple problem

The fact to be decided is whether or not immobilisation after a recent dislocation of the shoulder is a contributory factor to the development of recurrent dislocation As you say, no protagonist of either side really knows, but to add "one of them must be wrong" is carrying logical positivism too far It is highly probable that one group of shoulder dislocations, possibly those associated with a deep depression on the head, always recur regardless of the treatment, and another group, without bone injury, show a reduced recurrence rate after adequate immobilisation In fact very considerable attention has been given to this problem, and the failure to solve it suggests that there must be some overlapping of the effects of immobilisation and non immobilisation, and is strong evidence that both sides might be right!

The leader goes on to state that "A definite answer could be given by a follow up study of a few hundred cases treated by each method" This is an over simplification The fact is, that we have not even got an accurate figure for the recurrence rate in a hundred cases treated

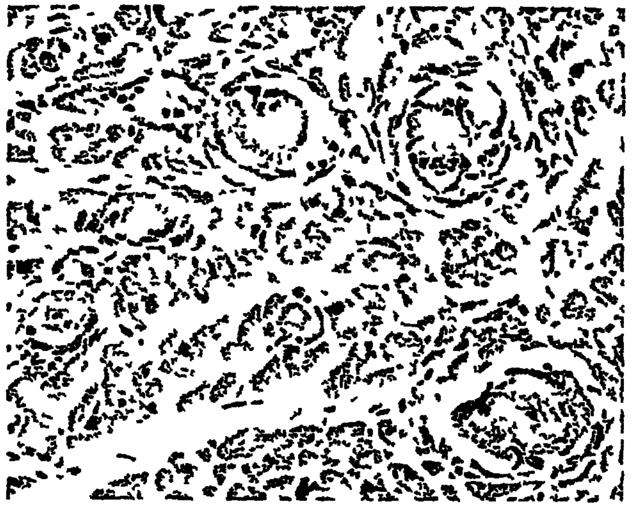

Fig 1—Thrombotic microangiopathy in dilated myocardial capillaries in case 1 (Hæmatoxylin and eosin × 250.)

Admission.—No treatment could be given at the time of biopsy because the patient was unwilling to remain under medical care; seven days later he was admitted to hospital because of sudden, painless hæmaturia. Temperature 99.4°F. He was very pale; clinical examination showed no other abnormalities, apart from the lymphadenopathy. Next day the patient was restless and confused, and had become slightly jaundiced; slight hæmaturia persisted, and blood oozed from his gums.

Investigations.—Empirical liver function tests normal. Serum bilirubin level 4.8 mg. per 100 ml.; serum albumin level 3.6 g. and serum globulin level 3.2 g. per 100 ml. Prothrombin, bleeding, and clotting times normal. Blood count: red cells 3,800,000 per c.mm.; Hb 11.0 g. per 100 ml.; white cells 13,000 per c.mm. (neutrophil polymorphs 9100, myelocytes 260, myeloblasts 65, eosinophils 260, lymphocytes 2665, monocytes 650); platelets scanty.

Treatment and course.—Blood transfusions had no effect on the clinical or hæmatological picture. Treatment with cortisone (300 mg. daily) was started on the patient's third day in hospital. Four days later he passed into a muttering delirium; his condition rapidly weakened, and he died in coma. No hæmorrhages were found in the skin at any time, and the tourniquet test was negative.

Investigations on day of death.—Blood-count: red cells 1,800,000 per c.mm. (12% reticulocytes); 6 normoblasts per 200 white cells; Hb 5.6 g. per 100 ml.; white cells 28,000 per c.mm. (neutrophil polymorphs 22,960, myelocytes 840, myeloblasts 140, eosinophils 280, lymphocytes 3080, monocytes 700); platelets 62,000 per c.mm. No red cell agglutination or hæmolysis in albuminous or saline media at 4°, 18°, or 37°C; Coombs test negative.

Necropsy.—Necropsy sixteen hours after death showed generalised, moderate enlargement of lymph nodes throughout the body, a few serosal and mucosal petechiæ, a spleniculus (weighing 35 g.) at site of splenectomy, and red marrow throughout the upper half of a femur and humerus.

Histological examination showed typical lesions of thrombotic microangiopathy, abundant in the myocardium (fig. 1), adrenals, lymph nodes, tonsils, pancreas, and bone marrow, and scantier in the hepatic portal tracts, cerebral grey matter, and spleniculus; *none* was found in the skin, skeletal muscle, or kidneys. Sections of marrow showed erythroid and myeloid hyperplasia; the megakaryocytes looked normal. There was no evidence of leukæmia or extramedullary hæmopoiesis.

Lymphadenopathy as the presenting manifestation of thrombotic microangiopathy has not been described before. Enlarged lymph-nodes, apart from septic lymphadenitis, were noted in only 6 cases (Engel et al. 1947, Fitzgerald et al. 1947, Clinicopathologic Conference 1951, Barondess 1952, Laszlo et al. 1955, Prokš and Tomší 1955a and b); in none of these was the lymphadenopathy as striking as in this case. Purpura is rarely absent, as it was here; hæmaturia has been noted often, and may be the presenting symptom. Leukæmoid blood pictures have often been described and may be present only transitorily; in Ritama's (1954) case the picture was that of acute myeloid leukæmia. An unusual feature of the case described above was the absence of clinical abnormalities of the nervous system other than confusion and terminal delirium, which may have been nonspecific accompaniments of a severe illness.

PRESENTING WITH CONVULSION AND MENORRHAGIA

Case 2.—A woman, aged 21, was admitted to hospital half an hour after a fit while sleeping in the sun. Her sister, a qualified nurse, said that they had sunbathed for four hours; she described the fit as a major epileptiform convulsion, and it was noted in hospital that the patient's sun suit was soaked with urine and that her tongue was bitten. There was no *previous history of epilepsy or of any untoward reaction to* exposure to the sun. She had previously had only trivial illnesses; since puberty she had been liable to boils, for which she occasionally took sulphonamides. Three weeks before the convulsion she had had a sore throat and pyrexia, treated with tablets containing sulphathiazole, sulphadiazine, and sulphamerazine; during this treatment a transient maculopapular rash developed.

On admission she was unconscious. Temperature 97.4°F. Pulse rate 42 per min. Urine normal. She was menstruating scantily. Heart normal; blood pressure 120/70 mm. Hg; electrocardiography showed sinus bradycardia. Pupils unequal in size, but reacted to light; tendon reflexes elicited with difficulty; abdominal reflexes absent; left plantar reflex extensor, right flexor.

Progress.—Two hours after admission the patient regained consciousness and complained of headache and thirst. Temperature 99.6°F; pulse rate 110 per min. Two hours later she had a rigor (temp. 106.8°F); she was pale and weak, her pulse rate was 148 per min.; and she had bled copiously per vaginam. (Her menstrual history was normal, except that the present period was a fortnight late.) 5 pints (2.8 litres) of blood were transfused within two hours; the bleeding stopped soon after transfusion began. Next morning, eighteen hours after the convulsion, she felt well but tired. There had been no further vaginal loss, and there were now no neurological abnormalities. Blood count: red cells 4,600,000 per c.mm.; Hb 12.0 g. per 100 ml.; white cells 7500 per c.mm. (normal differential count); platelets 310,000 per c.mm. That night uterine bleeding recurred; curettage was performed, and the bleeding stopped.

Histological examination of the curettings showed hæmorrhagic, menstruating endometrium; in addition, lesions typical of thrombotic microangiopathy were seen in the basal stratum of the endometrium and in the endocervix.

Repeated clinical examinations showed nothing abnormal apart from widespread sunburn (erythema without blistering) and slight evening fever. A patch test with sulphathiazole was positive.

Laboratory investigations were consistently negative, apart from erythroid hyperplasia in marrow films and a reticulocyte count of 5%. Red cell, white cell, and platelet counts,

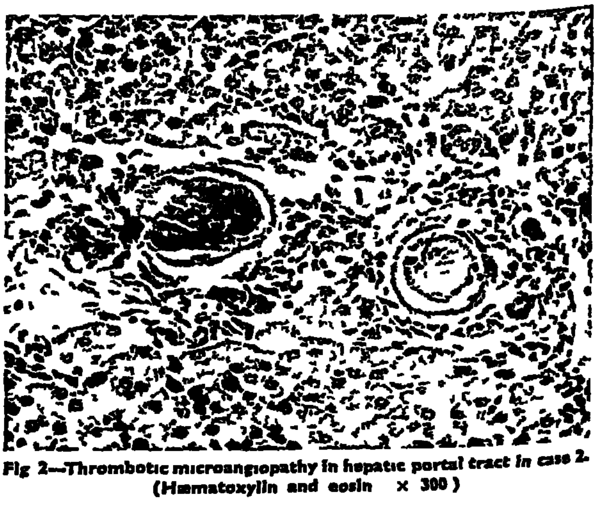

Fig 2—Thrombotic microangiopathy in hepatic portal tract in case 2. (Hæmatoxylin and eosin × 300.)

The sole purpose of the procedure is to help in the early selection of the case that must be treated by surgery The method is so simple and safe that I can see only two valid objections to its use one medical and one surgical. The dosage of adrenaline employed is unlikely to receive ready acceptance by one who has been trained to use it in carefully calibrated doses of up to as much as 1 ml or by the young surgeon who must depend on emergency operations for his quota of gastric surgery

"Men occasionally stumble over the truth but most of them pick themselves up and hurry off as if nothing had happened" (Sir Winston Churchill)

PREVENTION OF RENAL LESIONS DUE TO ISCHÆMIA

SIR,—In view of the interest aroused by "artificial hibernation" we wish to draw attention to the effect of this procedure on ischæmic lesions of the kidney

Renal ischæmia constitutes a major problem in operations for partial nephrectomy and in shock

Partial nephrectomy necessitates temporary compression of renal vessels No untoward consequences result from this if the other kidney is normal, since function is restored within a few weeks, even after circulation has been arrested for a whole hour On the other hand if the patient has only one kidney and this must be operated on, ischæmia of ten minutes' duration may be tolerated, but the safety margin is dangerously narrow and the outcome depends mainly on the duration of ischæmia [1]

In *shock*, whether due to injury loss of blood, or any other factor, one of the chief complications is a renal lesion, which has caused the death of many a patient whose circulatory equilibrium had successfully been restored [2] The lesion, whether directly or indirectly, is always the consequence of ischæmia The tubular system is injured by anoxia simultaneously with the decrease of circulation there is a decrease in glomerular filtration, and, in consequence of anuria, in the tubules casts are formed and toxic effects manifest themselves [2, 3]

In animals, clamping the renal artery for four hours, three to four weeks after the other kidney has been removed, usually leads to death in uræmia Compression for two hours is usually survived, although complete restoration of renal function takes two to three weeks [4–6]

The pathogenesis of uræmia following renal ischæmia is identical with that associated with shock, and the morphological changes are also the same [5, 7] Considering that in both forms the basic problem is the disproportion between oxygen need and oxygen supply, it was assumed that by decreasing the tissues' oxygen demand it should be possible to prevent injury by ischæmia Experiments were therefore carried out to study the development of the lesions in hypothermia after administration of chlorpromazine

12 dogs which had had their right kidney removed three weeks before were used in the experiments They were divided into two groups In the control group of 6 animals, the renal artery was clamped for four hours at normal body-temperature In the "hibernated" group first 5 mg of chlorpromazine per kg body weight was administered in an intravenous infusion in two hours Then the animals were cooled to 24–25°C, and the renal artery was laid bare and compressed by means of a surgical clamp, with care to avoid crushing the accompanying nerves After four hours the clamp was released and the animals were re warmed Before arresting renal circulation, two normal clearance periods had been registered and also the non protein nitrogen level in the plasma After releasing the artery it was checked whether circulation had become normal in the kidney For fourteen days plasma non protein nitrogen values, and *p* amino hippurate and creatinine clearances, were determined every day in each animal The survivors were killed on the fourteenth day

Of the 6 animals in the control group, 5 died of uræmia within nine days Their plasma non protein nitrogen level ranged from 156 mg to 297 mg per 100 ml from the fourth day onwards Uræmia had also developed in the 6th dog, but this subsided by the fourteenth day In the hypothermic group all 6 animals survived In 5 animals the non protein-nitrogen level did not rise above the upper limit of normal (26–40 mg per 100 ml), in 1 there were high values for a few days

In the control group, grave cortical necrosis was present in every kidney, with calcium deposits in the tubules, extensive œdema, epithelial necrosis, and masses of casts, and in addition cellular infiltration from the renal pelvis In the hypothermic group, renal lesions were very slight, not exceeding some hydropic degeneration of a few tubules

In the control group, by the fourth day the clearance of *p* aminohippurate had decreased, on average, to 26% of the initial value, that of creatinine, to 16% (in agreement with the findings of others [8, 9]) In the hibernated group, *p* amino hippurate clearance remained normal in 4 dogs, while in the other 2 it decreased temporarily but regained the initial value before the fourteenth day Creatinine clearance did not change in 3 dogs, in 3 it decreased by 20–29%, and in 2 of these it was normal before the fourteenth day

We conclude from these observations that the lethal kidney lesion which develops as a result of ischæmia can practically be prevented by administration of chlorpromazine and subsequent cooling Since in previous experiments [10] it was found that the changes in renal function occurring in hypothermia do not persist after body-temperature has been raised to normal, on the basis of the present findings we feel justified in recommending administration of chlorpromazine and subsequent hypothermia preoperatively for operations in the course of which renal circulation is arrested Moreover, it seems probable that this procedure may help to prevent the renal lesions associated with shock

The findings described here are to appear in full in *Acta Physiologica Hungarica*

Births, Marriages, and Deaths

BIRTHS

OSTLERE—On April 19 at King s College Hospital, S E 5 to Mary (née Patten) and Gordon Ostlere—a son

DEATHS

MORRISH—On April 14 at Stafford, William John Morrish M D Lond M R C P, D P H late of Streatham Park London S W 16 spread but scanty serosal petechiæ Her appendix was removed

Histological examination of the appendix showed thrombotic microangiopathy in the mucosal and subserosal vessels, there was no other abnormality The significance of the vascular changes was missed at this time, and it was not until the pathologist saw sections from another case of thrombotic microangiopathy at a medical meeting some weeks later that he realised the nature of the lesions he had seen in the appendix He learned then that the patient had subsequently died elsewhere

Course —The patient had returned to school four weeks after the appendicectomy, seemingly well but a little pale and tired, due, it was thought, to the operation and epistaxis since then Two days after going back to school she complained of sudden headache, which rapidly became intolerable She had photophobia, neck rigidity, and a positive Kernig's sign, there was a macular rash on her trunk, with punctate hæmorrhage in some macules, and her temperature was 104°F She was admitted to hospital immediately as a probable case of meningococcal meningitis

On admission she was unconscious, shocked, and pulseless She was given 1 million units of penicillin and 50 mg of cortisone four hourly, as it was believed that she had developed the Waterhouse Friderichsen syndrome, the shock like state improved considerably, although she remained unconscious

Investigations —The C S F was uniformly bloodstained, no organisms were found in films or cultures Blood culture sterile Blood count red cells 2,600,000 per c.mm, Hb 6 3 g per 100 ml, white cells 8000 per c mm (neutrophils 6400, eosinophils 400, lymphocytes 1200), platelets 36,000 per c mm *When her coma lightened she was found to have* right sided hemiplegia, and cerebral hæmorrhage due to thrombocytopenia was then diagnosed She died on the day after admission

Necropsy —There were many petechiæ and ecchymoses in the skin and serosæ A very large hæmorrhage in the left cerebral hemisphere had burst into the lateral ventricle The other organs looked healthy

Histological examination showed thrombotic microangiopathy in the cerebral cortex, myocardium (fig 3), adrenals, and liver, no other tissues were sectioned

Abdominal pain has been reported in 15 cases of thrombotic microangiopathy (Altschule 1942, Engel et al 1947, Fitzgerald et al 1947, Muirhead et al 1948, Clinicopathologic Conference 1951, Symmers and Gillett 1951, Barondess 1952, Rackow et al 1952, Vassar and Spain 1953, Revill and Wilson 1954, Radnai et al 1954, Ritama 1954) It was a presenting symptom in 10 of these cases The patient whose case Gillett and I reported had polyarteritis nodosa, with an aneurysm in the pyloric region Of the cases reported by Vassar and Spain (1953) 1 had a chronic gastric ulcer and another had acute gastric ulcers, Ritama's (1954) patient had also had a chronic gastric ulcer In the rest of the cases there was no clear explanation of the pain

Laparotomy was done only in the present case, the finding of peritoneal petechiæ is noteworthy, especially as their significance was not then appreciated

Although the hæmolytic nature of the anæmia was not confirmed, this case was the only one of the 3 reported here in which the full tetrad of acute febrile illness, (hæmolytic) anæmia, thrombocytopenic purpura, and neurological disturbances developed The neurological manifestations were not of the classical changing and evanescent type observed in case 2

Massive intracerebral hæmorrhage has not been described in any published cases of thrombotic microangiopathy, but Adams et al (1948) mentioned an unpublished case in which a large hæmorrhage in the brain was the cause of death In most cases cerebral bleeding is petechial only, larger hæmorrhages (a centimetre or two in diameter) were described by Green and Rosenthal (1949), Pagel (1949), Meacham et al (1951), and March (1954)

Summary

The possible value of biopsy in the diagnosis of thrombotic microangiopathy is discussed

Biopsy, which so far has played little part in the study of this disease, should be considered as soon as the diagnosis is suspected, so that time may be gained for investigation of the disease and of possible lines of treatment

Combined rib, muscle, and skin biopsy may prove to be the method of choice

3 cases are described in which the diagnostic histological changes of thrombotic microangiopathy were found in surgical specimens (lymph-node, uterine curettings, and appendix) before the clinical syndrome developed

Notes and News

FORWARDS IN MANCHESTER

"As a first step towards improving medical education in our University," Manchester are making some small but important adjustments in their curriculum[1] Revision had become demonstrably necessary because of the difficulty of arranging a time table classes clashed, students were doing clinical work in one subject while taking an examination in another, and no fewer than four examinations had to be taken in the last 18 months The object of the new arrangements is to remove these faults, to reduce the content of the course to free at least one long vacation, and to provide a period, at the end of the course for general revision

In the new curriculum the 2nd M B examination will be held 3 months earlier, and the introductory course preceding the clinical period will be discontinued in favour of a different type of instruction to students during their first medical and surgical appointments The time spent in the ear nose, and throat, eye, and skin departments will be reduced from 3 months to 6 weeks and the period at the skin hospital from a month to a fortnight The gynæcological appointment will be postponed to the final year and will include revision in obstetrics and pædiatrics Forensic medicine will have a terminal examination and social and preventive medicine will (very properly) come into all four subjects of the final (obstetrics and gynæcology, pædiatrics, medicine, and surgery) These and other changes will mean that no big examination is held between March of the fourth year and June of the sixth

Only those who have tried to alter a curriculum have a true conception of the difficulty of making even minor changes We congratulate the Manchester school on their improvements and trust that time will prove them right in describing these as "a beginning"

HOSPITAL ADMINISTRATIVE STAFF

LAST year in discussing the recruitment of hospital administrators[2] we mentioned a suggestion that King Edward's Hospital Fund should organise appropriate training for these men and women The need for such a plan was urged more lately in the Guillebaud report and by the Whitley Council for administrative and clerical staffs The King's Fund[3] has already announced its willingness to help and now the Government has launched a scheme that will make use of the Fund's offer

Trainees, who may be from inside or outside the hospital service, will be selected to fill training posts for a course of a maximum of three years They will be given practical experience of all branches of administration with different hospital authorities, along with courses of instruction at the Hospital Administrative Staff College of the Fund or the University of Manchester 16 posts are available for the first course, beginning in September The starting salary for trainees will be £540 (plus a small addition in the London area) with an increase of £20 in the second and third years Trainees already in the hospital service will retain their present salary if higher than this Fees and other expenses during training will be met Young people under 18 in the hospital service will be helped to continue their general education, and hospitals will be encouraged to institute on the job training schemes to give them experience of various types of work.

HEALTH IN INDUSTRY

THE London Transport Executive have published a detailed statistical analysis on sickness absence—"the absence from work accepted by the employer as attributable to sickness or injury"—among their employees[4] The book is the first analysis of its kind, and it will provide a standard for all concerned with the study of health in various branches of industry

Sickness absence statistics are not synonymous with morbidity statistics The records do not cover the episodes of sickness or injury which do not prevent the patient from following his employment chronic ill health which compels the patient to give up work altogether, or the sickness and injury of persons who are not employed and therefore do not come under an employer's observation They include, however, many short spells of absence which are not registered for National Insurance or friendly society purposes, because of the "waiting days" for benefit The problem is thus a specialised one, not covered in statistical tables hitherto available Its magnitude is reflected in a statement by the *Manchester Guardian*[5] "About seven million claims for sickness benefit are made each year, and the number of short absences from work because of sickness for which no claims are made is believed to be another six million"

The data given in this book raise a number of questions of social and medical importance An interesting finding, for example, is that sickness which lasts more than four days tends to be measured in whole weeks Though this will need further elucidation, it seems that National Insurance regulations keep people away from work when they would otherwise be well enough to return On the other hand, we all know that a few days' convalescence after an acute illness may prove of benefit in the long run Another problem of great importance is the comparison between the periods of sickness absences of the under 45 and over-45 It would seem that, though long spells of absence, due to serious illness, are more common over the age of 45, short sickness absences are considerably commoner in the younger age group

SALARIES IN THE PUBLIC-HEALTH SERVICE

COMMITTEE C of the medical Whitley Council announces that agreement has been reached between the staff and management sides to recommend an increase in the salaries of doctors in the public health service as from April 1, 1956 The increase will be of $7^1/_2$% on the first £1250 of salary and of 5% on the excess of salary over £1250

IMPROVING A FIREGUARD

Dr G R Hervey writes Open fires still cause fatal accidents to children, in some instances even though a fire guard was in use The type of guard which seems to be most commonly used today is good in that it has a closely woven wire mesh, but less good in being so light that it can easily be moved by a one year old Fastening the guard to the fireplace overcomes this danger and greatly increases the safety given by the guard The accompanying figure shows one way in which this can be done, and the work required is well within the scope of any handyman' The lugs are made from small pieces of sheet metal The studs in the wall are $1^1/_2$ in × no 14 woodscrews with the heads cut off and the straight part of the shanks threaded with $^1/_4$ in Whitworth threads Fixing them is easier than it looks A hole is drilled through the tile and the cement beneath it with a no 14 'Durium' drill, a no 12 'Rawlplug' is inserted, and the stud is screwed in, held by two nuts temporarily screwed on to the shank and locked against each other These are subsequently replaced by the wing nuts and washers shown If loosening or tightening the wing nuts when the guard is moved is thought unduly burdensome, they can be replaced by domed washers backed by spring washers to give a friction grip A further modification made to this particular guard was the addition of a piece of expanded metal at the top to close a gap which

there was no sensory change and little difference of power between the two sides

The aneurysm formed at the site of pressure of the axillary crutch on the arm and probably gave rise to an embolus, which lodged at the bifurcation of the brachial artery, producing the acute symptoms in March, 1954 It is uncertain whether the poor filling of the radial artery is a congenital abnormality or due to occlusion of the brachial bifurcation In view of this, and the possibility of further embolism, sympathectomy was done to maintain the collateral circulation and to prevent occlusion by spasm in the event of further embolism

Acute Thrombosis Due to a Blow

Case 5 —A man, aged 19, was, in May, 1954, standing on his bed cleaning his locker in an Army hut, when his friends pulled the bed from beneath him As he fell, the open door of the locker was between his left arm and his body, and its upper edge struck him a sharp blow on the arm just below the axilla Next morning his hand was cold, white, and powerless, and the hand and forearm were aching No pulse was palpable below the axilla Arteriography confirmed the diagnosis of thrombosis of the brachial artery

Operations —On June 18, 1954, at Queen Alexandra's Military Hospital, Millbank, the affected segment of artery was excised and an autogenous venous graft inserted Thrombosis developed in the graft, and on Sept 27, 1954, sympathetic ganglionectomy was done, removing the lower half of the stellate ganglion and the chain as far as the third thoracic ganglion A week later secondary hæmorrhage necessitated ligation of the second part of the subclavian artery

Follow up —When last seen in April, 1955, he had regained virtually normal use of his left arm, but found it a little weaker than his right There were no colour changes in the digits, but there was a delay of a few seconds in reactive hyperæmia There was still no palpable pulse in the arm

This case illustrates well the severe symptoms which may follow sudden occlusion of the main artery of a limb, and the good recovery which may ensue in the upper limb even after the loss of an extensive segment of the vessel

Case 6 —*A man, aged 45, slipped at work in 1953 and struck* the inner side of his right arm against the edge of a large wooden box Next day his hand was white and cold, and he had in the forearm an aching pain which was worse on raising his arm Severe ischæmic pain developed in the forearm muscles on attempting to use the limb When he was first seen by us in *October, 1955*, there had been *little* improvement The hand was still pale and cooler than its fellow, and he complained of pins and needles in his finger tips on raising his arm He found lathering his face difficult and could not satisfactorily strop his razor Using a hammer quickly produced ischæmic pain in the forearm

On examination the axillary pulse was normal, the brachial impalpable, and the radial much weaker on the affected than on the normal side Capillary blanching tests showed appreciable delay in the peripheral circulation in the fingers The diagnosis of thrombosis of the brachial artery was confirmed by arteriography, which showed local narrowing, amounting almost to occlusion, of a short segment of the artery in the middle third of the arm The vessels above and below appeared normal, and the films revealed no cause for the narrowing

Operation —Upper thoracic sympathetic ganglionectomy was done on Oct 24, 1955, and next day the hand was warm and of normal colour *The patient shaved without difficulty* and stropped his razor for the first time since his accident, there has been no further paræsthesia

Arterial Injury Associated with Skeletal Injury

Case 7 —A man, aged 22, was involved in a road accident at 11 P M on Oct 4, 1953, and admitted to hospital, where he was found to have an unstable fracture of the upper third of the right humerus, with no radial pulse on this side The hand was cold and blue, and there was no response to tolazoline or to papaverine He was admitted to St Mary's Hospital at 4 A M on Oct 5, 1953, in good general condition, with blood pressure 130/95 mm Hg There was considerable swelling of the upper arm and axilla, and the distal part of the limb was cold and blue as high as the upper third of the forearm No pulsation was detected below the axilla, and the capillary blanching test on the fingers showed a return of blood in 14 sec Despite these findings, power in the wrist and fingers was good, and there was no sensory disturbance The probable diagnosis was considered to be traumatic arterial spasm, and reflex heating was begun Four hours later the hand was warm and of normal colour, and the capillary blanching test was normal, but the arterial pulses were still absent

Operation —The fracture was therefore exposed and plated, and the main vessels were explored The posterior humeral circumflex artery had been torn from the axillary, and at this point there was a severe contusion of the main artery, with thrombosis for 8 mm Strong pulsation was present proximally The affected segment was excised and a freeze dried homograft inserted

Progress —Convalescence was normal, and in July, 1955, the patient reported his arm normal in all respects, and all pulses were present and equal on both sides

This case was explored despite the evidence of excellent collateral circulation, primarily to treat the unstable fracture, and the opportunity was taken to explore and repair the damaged artery

Case 8 was also of this type, rupture of the axillary artery being associated with anterior dislocation of the shoulder joint in an elderly patient This was treated by direct end to end anastomosis, with satisfactory restoration of the blood flow The arterial pulses were equal on the two sides when he was last seen three months after operation

Discussion

The group of patients who used an axillary crutch is of interest All the patients had used this type of crutch from childhood and for about fifty years before the onset of symptoms They had, in fact, used their arms as legs for most of their lives and entered the age group in which arteriosclerotic occlusions of the arteries to the lower limbs are becoming common During the three years in which these patients were seen only 1 was seen with spontaneous occlusion of an upper limb artery, compared with 225 patients who developed similar lesions in the arteries of the lower limbs It is therefore suggested that the stresses and strains normally borne by the lower limbs had been transmitted to the arms with comparable effects on the vessels

In none of these patients was there any evidence of damage to the axillary vein or to nerves, although the whole of the neurovascular bundle must be stretched over the head of the crutch and its components exposed to much the same pressure Nevertheless, all these lesions occurred at the site of pressure of the crutch on the limb, and clearly the trauma thus occasioned to the artery is a major factor in determining the onset of occlusion The diagnosis of occlusion of the axillary artery presents few difficulties, but in the management of occlusion several factors must be taken into consideration

(1) The prognosis is better than in similar lesions of the femoral artery, in that gangrene is less likely to supervene and, except in manual workers, any resultant ischæmic muscle pain is less of a disability in the arm than in the leg

(2) The site and extent of the block, by their effects on the collateral circulation, have an important bearing on the final disability

(3) The rate at which the artery becomes occluded largely determines the fate of the limb Gradual occlusion allows time for the collateral vessels to enlarge and to provide adequate channels when occlusion of the main vessel becomes complete, with the result that symptoms may occur only on exercising the limb A sudden occlusion, however, accompanied (as it may be) by spasm of a length of the artery and its collaterals, may leave the limb virtually bloodless and produce severe initial symptoms, with the danger of peripheral gangrene Gask (1913) quotes 2 cases of axillary thrombosis in which gangrene supervened

In cases of acute onset the aims of treatment are to prevent spread of the thrombosis and to dilate the

OSTEO-ARTHRITIS

AN APPROACH TO SURGICAL TREATMENT*

J Trueta

M A M D D Sc Oxfd F R C S F R F P S F R C S (C)

NUFFIELD PROFESSOR OF ORTHOPÆDIC SURGERY IN THE UNIVERSITY OF OXFORD

The findings reported here have been collected during the last four years or so and refer to the condition known in this country as osteo arthritis and in others as arthrosis This is, together with poliomyelitis, the most common of the severe disorders (other than the traumatic) *for whose treatment the orthopædic surgeon is responsible* One can foresee the day when paralytic poliomyelitis will rank with the other diseases—such as chronic osteo myelitis, skeletal tuberculosis, and rickets—which formerly constituted great orthopædic problems but are now becoming rare , but there has been nothing to raise our hopes of any early control of osteo-arthritis We are still in the unhappy situation of being forced to observe the progressive deterioration of the joint until, in many cases, it is sufficiently advanced to justify a major operation, for all lesser treatments so far attempted —lactic acid and other intra articular injections, cortisone, physiotherapy, hydrotherapy, and radiotherapy—have only too often failed to bring permanent relief

The present investigation was undertaken in the hope of learning something of the pathological changes in the early stages of the disease The main results of this work have already been published (Harrison et al 1953, Trueta 1953 1954), but since then I have gathered new facts from further experiments

Weight-bearing and Osteo-arthritis

The main conclusions already reported referred to the relationship between osteo arthritis and gravitation We found that the factor chiefly responsible for the initiation of the degenerative changes is the wrong distribution of intra articular pressures, which enabled us to explain why, in order of severity and frequency of occurrence, the spine, the hip, and the knee follow close to each other, with the ankle much less commonly affected Another finding was that the disorder begins always in the cartilage which, when it degenerates, is profusely invaded by vessels coming from the underlying areas of bone This vascular proliferation is responsible for changing the cartilage of the non-weight-bearing area into bone (osteophyte) and also for weakening the resistance of the bone in the weight bearing area Here the orientation of the trabeculæ permits an exact appreciation of the line of gravitation and thus of the exact position in which the femur is or was, held during life An explanation will be offered later of the mechanism underlying the reorientation of the trabeculæ which follow the lines of gravitation and increase the resistance of the bone

In the head of the femur the weight-bearing area which is submitted to increased direct pressure by the loss of the resilience and elastic protection of the cartilage begins to crumble away The bone thickens and acquires the radiological characteristics known as sclerosis or bone condensation The sclerosed area is cone shaped with the base of the cone on the surface of the bone and its vertex directed towards the centre (fig 1) It is an area of higher vascularisation and not of ischæmia as is commonly believed (fig 2) Nevertheless in the midst of this profuse vascularity and robust bone structure we find the so called bone cysts that contain fibrous, devitalised and sometimes even amorphous tissue

Orientation of Bone Trabeculæ

Both in the initial hypothesis and in the course of our work we suspected that the whole disorganisation of the joint including the vascular reaction leading to either bone atrophy or bone proliferation, was due to the inability of the cancellous bone to discharge its structural requirements once the hyaline cartilage had lost its resilience and elasticity

In higher animals and in both primitive and contemporary man evolution is evident in the type and direction of gravitational trabeculæ of the femoral head and neck In the gorilla the trabeculæ run, like the folds of an open fan towards all areas of the head (fig 3) , the same is found in a human child up to the age of 6 or 7 years In Neanderthal man we find the trabeculisation similar to that of a present-day boy aged 14 or 15 (fig 4) but in mature contemporary man the trabeculæ are concentrated towards the upper part of the head, the area which usually takes the weight in the standing position and also suffers the impact of the locking of the joint The ontogenic changes in man repeat here the phylogenic evolution We have acquired the ability of locking the hip joint in full extension—an ability which was not possessed by primitive man or by the apes (fig 5)

Apart from any contribution which endocrine or infectious disorders could make to early degeneration of the cartilage, osteo arthritis seems to be connected with the abnormal distribution of pressures within the joint The part of the cartilage which has not taken weight

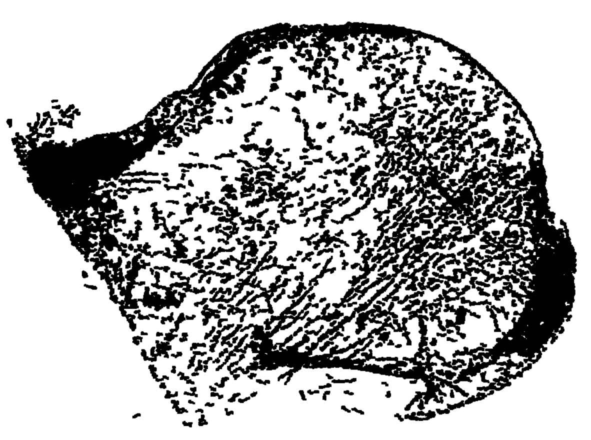

Fig 1—Section of osteo-arthritic femoral head showing triangular shape of area of sclerosed bone corresponding to weight bearing zone and osteophytes of non weight-bearing zone Sclerosis is conic in shape in unsectioned head

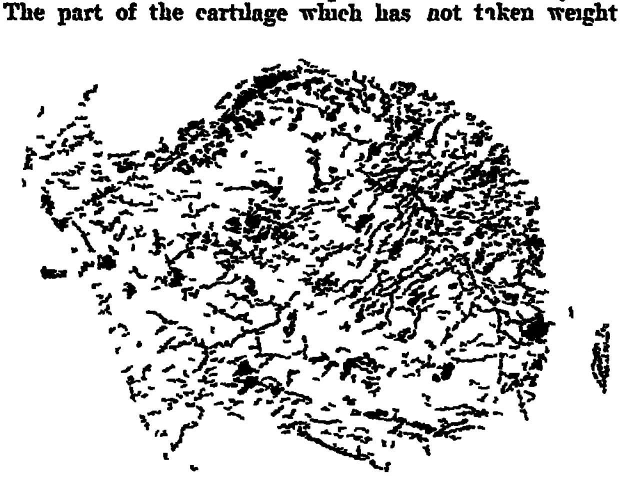

Fig 2—Highly vascular area almost exactly corresponding to zone of sclerosed bone

* 100 % = 14 5 g per 100 ml

possible Cases yielding more than one hæmolysed sample were omitted from the final analysis (see table II)

Hæmoglobin Levels During Pregnancy

In the City of Nottingham a sample of blood is taken from every expectant mother at her first visit to one of the ten antenatal centres of the local health authority The mean Hb levels of 4635 blood samples examined in 1951–52 are shown in table I

The mean Hb level is seen to be lower in patients whose pregnancy was more advanced, and the percentage of expectant mothers with a Hb level below the lower limit suggested by Adair et al (1936) is seen to be higher, the later they attend for their first visit

Benstead and Theobald (1952) showed that this "physiological anæmia" could be abolished by a dose of gr 18 of ferrous sulphate daily from the 24th to the 32nd week of pregnancy If this "physiological anæmia" can be abolished by a therapeutic dosage of iron from the 24th week, it should be possible to prevent its appearance by a smaller dosage of ferrous sulphate from an earlier stage, provided the mother is not already anæmic This was the principle underlying the present investigation

Material

In the first six months of 1953, 179 mothers whose Hb levels were not below 10 5 g per 100 ml volunteered to take part in the investigation They were divided into four groups according to the stage of pregnancy at which iron was introduced, as follows 16th week (30), 20th week (61), 24th week (45), and controls (43) Of these 179 women 65 (36 3%) yielded insufficient data to warrant their inclusion in the final analysis The reasons for their exclusion are shown in table II The remaining 114 mothers comprised 89 receiving iron and 25 controls

Hæmatological Findings

A detailed comparison of the findings in the control and 16th-week therapy groups is shown in table III and illustrated in the accompanying figure It was impossible to match these two groups exactly, but for the purposes of this study they are considered to be comparable in all relevant respects Thus, both groups were drawn from clinics in various parts of the city and received the same antenatal supervision The average age in the group receiving iron was 29 1 years and parity 2 5, compared with 28 1 years and parity 2 4 in the controls At the beginning of the investigation the Hb levels of both groups were similar

TABLE II—CAUSES OF EXCLUSION FROM INVESTIGATION

Group	Uncooperative or defaulted	Admitted to hospital	Premature delivery or abortion	Removed from area	Intolerance to iron	Hæmolysis of samples of blood	Hb fallen too low
Control	4	4	1	1	—	3	6
16th week	4	2	2	—	—	1	—
20th week	13	3	4	1	6	1	—
24th week	2	—	2	1	2	3	—
Total	23	9	9	3	8	7	6

In the control group there were the following findings

(1) A fall of 12% in the Hb level, maximal between the 32nd and the 36th weeks

(2) A fall of 13% in the red-cell count, maximal at 32 weeks

(3) A fall of 5% in the colour-index, maximal at 40 weeks

(4) A fall of 13% in the P C V, maximal between the 32nd and the 36th weeks

(5) A fall in the M C H C, maximal at 40 weeks

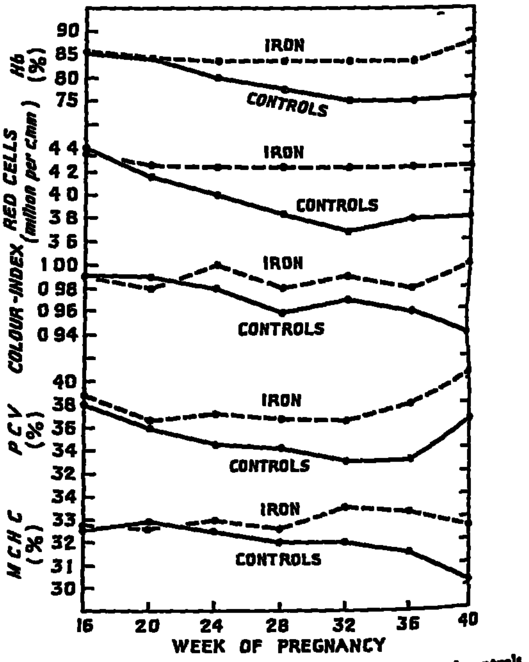
(6) An increase in the M C V, maximal at 40 weeks

All these findings, except the reduced colour index, are usually associated with the hydræmia of pregnancy

In the 16th-week therapy group all the estimations and indices were maintained within the limits of experimental error as defined by Whitby and Britton (1953), except the P C V which rose by 5 7%

To assess the value of the Hb level two further groups of mothers who received the same daily dose of ferrous sulphate were studied from the 20th and 24th weeks of pregnancy The findings are shown in table IV

In these two groups all the indices and the Hb levels were maintained The M C H C (the absolute index of iron deficiency) remained stationary, and the Hb levels, after a fall of 2–3%, reached at term a higher level than at the first examination



Hæmatological findings in 16th-week iron treated group and controls

In the three groups which received iron, therefore, the Hb levels and all the indices were maintained, whereas in the controls they all fell

Non-responders to Iron

Though it is true that the mean Hb levels were maintained throughout pregnancy in all three groups which received iron (tables III and V), there were some exceptions in each group Thus, of the 89 mothers who received iron there were 20 (22 4%) whose Hb levels were not maintained The hæmatological findings in these patients, comprising falls in Hb level, red cell count, P C V, colour index, and M C H C, were similar to those in the controls (The findings in these patients are included in the results given in tables III and IV) In all the cases been allowed to take place Some young rabbits, permitted to survive long enough, showed a progressive tendency to deformity of the knee caused by the early closure of part of one or other of the compressed epiphyseal cartilages In contrast to previous studies on the effect of pressure on the epiphyseal cartilage, we placed also the joint in the compressed area so that we could plot the joint changes against those of the epiphyseal cartilage

In a previous investigation (now in the course of publication) we had found that, if the blood supplying the metaphyseal side of the plate, or part of it, was interrupted, the layers of hypertrophic cartilaginous cells multiplied until often they were more than double the number of those of the normal cartilage (fig 7) The explanation is that blood is essential for the transformation of the cartilaginous columns of cells into bone, and in its absence these cells remain cartilaginous while new ones are added to the columns by the division of the basic layer at the epiphyseal end of the column When blood was allowed to penetrate the previously ischæmic area of the metaphysis, normal bone in its preliminary form appeared and the thickness of the cartilage was reduced to normal This tendency to recovery of the metaphyseal side of the growing cartilage was not paralleled by the cells of its epiphyseal side when submitted to an ischæmia of the same duration (fig 8) Then the ischæmic cartilage degenerated irreparably, and no further ossification took place when the blood was allowed to reach anew the ischæmic zone

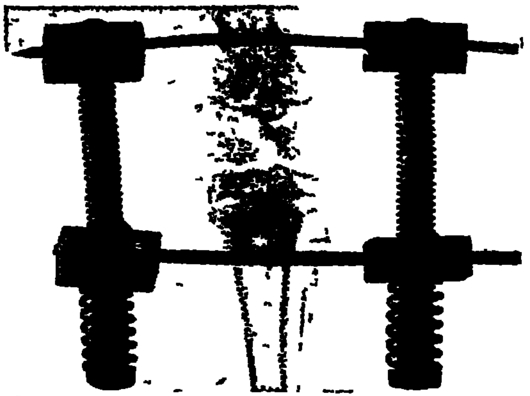


Fig 6—Apparatus used for compression of joint tissues, including epiphyseal plates, in growing rabbits

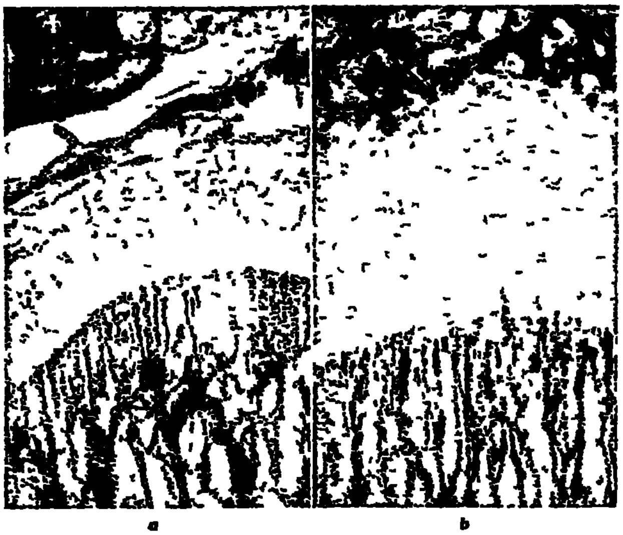

a b

Fig 7—(a) Normal epiphyseal plate with characteristic vascular loops , (b) metaphyseal blood flow has been substantially decreased by interposition of a polyethylene sheath

These experiments show that the behaviour of the epiphyseal cartilage depends largely on the rate of blood-flow near the two ends of its columns of cells Consequently the joint changes to be described here, obtained under the stress of persistent excessive pressure, if taking place together with the above-described alteration of the growing cartilage, can also be attributed to defective blood flow A few examples may suffice to show that this is so Following exactly the line of maximum pressure between the two transverse pins, we find in strict order advancing from the shaft towards the joint space (fig 9) (*a*) the increase in thickness of the growing cartilage , (*b*) above it some sclerotic thickened

TUBERCULIN IN AQUEOUS AND OILY SOLUTIONS

SKIN-TEST REACTIONS IN NORMAL SUBJECTS AND IN PATIENTS WITH SARCOIDOSIS

D GERAINT JAMES
M A, M D Camb, M R C P
LEVERHULME SCHOLAR, INSTITUTE OF CLINICAL RESEARCH, MIDDLESEX HOSPITAL MEDICAL SCHOOL, LONDON

J PEPYS
M B, M R C P, M R C P E
SENIOR LECTURER IN ALLERGY, INSTITUTE OF DISEASES OF THE CHEST, BROMPTON HOSPITAL, CLINICAL ASSISTANT, ALLERGY DEPARTMENT, WRIGHT FLEMING INSTITUTE, ST MARY'S HOSPITAL, LONDON

THE reaction to tuberculin in sensitised subjects depends on (1) the local persistence of the *tuberculin*, (2) the availability of sufficient antibody carrying cells, *and (3) the capacity of the tissues to react to inflammatory* stimuli resulting from the antigen antibody *reaction* The incorporation of tuberculin in an oily emulsion to form a "depot tuberculin" was found by Wassen (1936, 1939), Wassen and Swedin (1941), and Seeberg (1951*a*) to increase the local persistence of the tuberculin, leading to enhanced reactions of prolonged duration in sensitive subjects, and by Seeberg (1951b) to elicit positive reactions in patients with sarcoidosis, who had failed to react to *aqueous* tuberculin *solutions* The *conclusion* that the oily emulsion had prolonged the local persistence of the tuberculin is supported by the report of Talmage and Dixon (1953) that radioactivated proteins persist longer locally if mixed in a similar emulsion

We report here the results of comparing aqueous and "depot tuberculin" tests in

1 Normal Mantoux positive, normal Mantoux negative, and B C G vaccinated subjects
2 Patients suffering from sarcoidosis

Materials and Methods

Purified protein derivative of tuberculin (P P D, Weybridge) was used for testing in aqueous solution and in an emulsion consisting of 8 parts of light liquid paraffin *B P*, 1 part of anhydrous lanolin *B P* as the emulsifying agent, and 1 part of the appropriate concentration of the aqueous tubercul In the B C G -vaccinated subjects Old Tuberculin 1/100 w used throughout for the aqueous tuberculin testing Int dermal tests were made on the outer skin of the upper ar the volume of the injection being 0 1 ml of the aque tuberculin and 0 05 ml of the "depot tuberculin" and o the oily emulsion vehicle when this was used as a contr In preliminary *studies it was found that* P P D in a conce tration of 0 002 mg per ml *of the oily* emulsion gave a go reaction in sensitive persons, whereas higher concentratio *evoked too vigorous* reactions

Readings were made at forty eight hours and at interv *up to at least three* months Positive reactions to the "depot tuberculin" consisted of areas of erythema 20–40 *mm* i diameter with a central induration of 5–10 mm in diamete These reactions persisted long after any reactions to aqueo tuberculin had disappeared The possibility of non specifi irritation by the oily intradermal injection must be considered Seeberg (1951b) for example, *found that in tests made* on the thick skin of the thigh the vehicle excited erythemato reactions which could be readily distinguished from positive reactions to the "depot tuberculin" In this investigation the thinner, more elastic, skin of the upper arm was used, and there were no significant or enduring reactions at the sites where the vehicle alone was injected, or at the sites of the negative "depot tuberculin" tests These negative reactions to the oily material were marked by a barely palpable nodule in the skin

Results

Mantoux positive Normal Subjects

In 5 subjects giving positive reactions *to* 10 tuberculin units (T U) of aqueous tuberculin there were similar though more vigorous reactions to 5 T U of "depot tuberculin" at forty eight hours These reactions to both agents were 20–40 mm in diameter with central *induration 5–10 mm in diameter* The reactions to aqueous tuberculin subsided within the first seven to ten days, whereas the indurated erythematous reaction *to* the "depot tuberculin" persisted for two to three months, the erythema becoming duskier with time and showing superficial exfoliation

Mantoux-negative Subjects

18 normal subjects who failed to react *to* repeated intradermal injections of 100 T U *of* aqueous tuberculin also gave negative reactions to *5* T U of "depot tuberculin"

B C G -vaccinated Normal Subjects

9 healthy subjects who were negative to repeated *intradermal* tests with *100* T U of aqueous tuberculin (Old Tuberculin 1/100) were given intradermal injections of *the* "depot tuberculin," and *of* the vehicle, one month before the projected B C G vaccination Six weeks after the B C G vaccination, Mantoux tests were repeated with *100* T U of aqueous tuberculin on both arms for comparison with the earlier "depot tuberculin" tests The results were

Positive reactions to both aqueous and "depot" tests	[illegible]
Positive reactions to "depot" tests only	6
Positive reactions to aqueous tests only	3
Negative reactions to both aqueous and "depot" tests	

In 6 of the 9 subjects, reactions appeared at the sites of the previously negative "depot tuberculin" tests about ten days after the B C G vaccination They started insidiously with an area of erythema about 15 mm in diameter and became increasingly distinct during the ensuing week and remained unchanged for the next two months At this time the reactions became duskier and disappeared by the end of three months

5 persons failed to react to aqueous tuberculin after the B C G vaccination 4 of these had been vaccinated in the past and had either failed to convert or had converted transiently Of the 2 who reacted only to "depot tuberculin" and not to the aqueous tuberculin one was being vaccinated with B C G for the first time and the other was being revaccinated These 2 patients were studied *further by biopsy* examination of the B C G vaccinated sites, which showed active tuberculous

Causes of Failure of Arthroplasty

My own belief is that the biological, rather than the mechanical factors mentioned here are responsible for the failure of most current methods of arthroplasty The great contribution by Smith-Petersen had its benefits curtailed by the poor treatment that the metallic cup gave to the vessels of the femoral neck as much as by the great reduction in the area of the head bearing the gravitational stress The original method of the brothers Judet—a contribution which will be considered a landmark in progress towards a lasting solution—failed in numerous cases because the gravitational impact was too great for the vitality of the bone underlying and supporting the acrylic prosthesis New approaches by the Judets, Merle d'Aubigne Moore, Herbert, and others take into greater account the relatively frail nature of bone, and improvement in results must follow the use of methods that respect its vitality better I am trying a prosthesis which is mainly based on the experience of our previous failures, but also on the good features of both the Smith-Petersen and the Judet methods I prefer stainless steel and vitallium for their resistance and the absence of tissue reactions I use a large head whose contact with the newly moulded acetabulum resembles somewhat that of the Smith-Petersen cup—contact which was in general satisfactory (fig 13) Its shape is not far from that of the mushroom designed by the Judets the only essential difference is that it is connected to the neck not by the loose contact of the thick stem but by a screw with relatively large flanges and a narrow core

Preliminary results indicate that bone will remain alive between the flanges of the screw, as with previous types of screws The weight-bearing area—that of intimate contact between metal and bone—is very substantially augmented by the introduction of the large flanges The patient is kept off his feet for at least two months to allow sufficient time for the revascularisation of the central part of the neck in the spaces between the flanges So far the first part of the programme seems to be satisfactorily fulfilled The shortcomings, if any, of the method will probably appear before long

Conclusion

If, as I believe, osteo-arthritis is mainly a disease of the joint tissues and is caused by the wrong distribution of joint stresses, even in cases where an endocrine imbalance probably helps to weaken the resistance of the articular cartilage redistribution of pressures across the joint may bring lasting relief because the effects of excessive pressure are curable (Trueta 1954) It is this intrinsic curability of the osteo-arthritic process that makes me believe that, even in arthroplasty, lasting satisfactory results will be obtained when we learn to respect the laws of Nature, which work through the mediation of the blood-flow through the tissues Thus the explanation of Julius Wolff's law of the relation between function and form may be found in the stimulus that suffering or death has on life (in this study identified with the blood-vessels) in accordance with the dictum found in *Leviticus*, 17, 11 ' For the life of the flesh is in the blood "

THE SURVIVAL OF BACTERIAL SPECIES UNDER BACTERIOSTASIS

F C O VALENTINE
F R C P

READER IN CHEMOTHERAPY IN THE UNIVERSITY OF LONDON, AT THE LONDON HOSPITAL

In 1946 Dubos reported that, in the presence of gramicidin, pneumococci died rapidly whereas *Streptococcus fæcalis* might survive for many days Since then much work has been done on the interaction of antibiotics, including the effect of bacteriostatic drugs on the action of bactericidal drugs Jawetz and his fellow workers (see review, Jawetz et al 1954) have taken a leading part in this and have emphasised the fact that bacteriostasis may gradually sterilise a culture But little seems to have been said about the varying ability of different bacterial species to survive under such conditions

Accordingly I decided to test the survival of some of the commoner pathogens, incubated in culture media containing bacteriostatic drugs in concentrations comparable to those attained in the body during treatment If considerable differences were found in the survival of different species this would I thought go some way to explain why bacteriostatic drugs will eradicate certain types of clinical infection but not others The results reported were all obtained with chloramphenicol, but additional tests leave little doubt that, with sensitive bacteria, the effects of the other predominantly bacteriostatic antibiotics—including the tetracyclines and erythromycin—would be similar

Bacteria undergoing bacteriostasis exist in very delicate balance between life and death, easily upset in any single test by minute changes in the environment. and an investigation of this kind. depending on in-vitro tests, is inevitably somewhat artificial. An attempt has been made to attain greater realism by using broth enriched with horse blood, and this has introduced an additional factor of variability into the experiments Variability is likewise to be expected, however, when one is treating different patients

Method

1 To prevent evaporation of the medium, screw-capped containers (usually of 5–6 ml capacity) have been used to hold the 2 ml. of suspension under test

2 Since bacteria undergoing bacteriostasis are presumably unduly susceptible to harmful agents, which may be present in an occasional bottle after cleaning, each test should be at least duplicated Misgivings on this score have led to many repetitions of the work.

3 The medium must permit free multiplication of the bacteria and for this purpose nutrient broth is often adequate —having the advantage that it allows a fairly accurate count of surviving organisms Using this broth however the test becomes highly artificial in the case of an organism like the staphylococcus which is mainly diplococcal in broth but forms clumps in serum and in pus Much use has therefore been made of 20% horse blood broth, first employed for delicate bacteria, such as *Hæmophilus influenzæ* and pneumococcus, but later for other species It was surprising to find that many leucocytes were still alive in horse blood which had been kept refrigerated for a week or more and that a considerable degree of phagocytosis took place But, although some of the bacteria may have been destroyed in this way, it appeared that the remainder, being aggregated in small clumps of dying leucocytes were better able to survive It seemed therefore that the conditions approximated to some extent to those in an abscess and that for certain purposes horse-blood broth gave more realistic results than ordinary broth

The numbers of bacteria surviving were estimated by spreading a standard drop (or, later a loopful) of broth on a sector of a blood-agar plate Aggregations of bacteria in the blood broth made accurate counting theoretically impossible but it was found that in practice the method gave a useful

BASAL HORIZONTAL LINES ON CHEST RADIOGRAPHS

SIGNIFICANCE IN HEART-DISEASE

R E Rossall
B Sc, M B Leeds, M R C P
UNITED LEEDS HOSPITALS RESEARCH FELLOW,
DEPARTMENT OF MEDICINE, UNIVERSITY OF LEEDS

A J Gunning
M B Cape Town, F R C S
FIRST ASSISTANT, NUFFIELD DEPARTMENT OF SURGERY,
RADCLIFFE INFIRMARY, OXFORD

From the Departments of Thoracic Surgery, Radiology, and Medicine, The General Infirmary at Leeds

The value of radiology in the study of patients with mitral valvular disease is well established, and emphasis has recently been placed on the diagnosis of pulmonary hypertension from the chest radiograph Goodwin et al (1952) have described narrowing and tortuosity of the peripheral pulmonary vessels from angiocardiographic studies of patients with mitral stenosis and pulmonary hypertension Short horizontal lines at the periphery of the lower and mid zones of the lung fields were noted by Kerley (1951), and these too, have been regarded as a radiographic accompaniment of pulmonary hypertension in mitral stenosis (Goodwin et al 1952, Whitaker and Lodge 1953) Such lines may sometimes be a permanent feature of the patient's radiograph, in which case their pathological basis appears to be collagenous thickening with hæmosiderin deposition, occurring in the interalveolar septa (Parker and Weiss 1936, Fleischner and Reiner 1954) Transient lines, however, seem to be commoner, and these probably represent either dilated lymphatics (Kerley 1951) or the accumulation of tissue-fluid in the interalveolar septa (Gough 1955) In either case, the presence or absence of transient lines should depend on the magnitude of the pressure at the venous end of the pulmonary capillary, and Grainger and Hearn (1955) have described evidence in support of this A value approximating to this pressure can be obtained from calculations based on direct measurement of the left auricular pressure

The present study was undertaken to discover whether any relationship existed between the occurrence of these lines and either the left auricular or the pulmonary arterial pressure It was further hoped to reveal whether the magnitude of these pressures was a causal factor in the production of the lines

Materials and Methods

RADIOGRAPHIC METHOD

Standard postero-anterior radiographs were examined for basal horizontal lines, from 100 patients with mitral disease and 16 patients with pulmonary hypertension arising from other causes These films were then classified into three groups "lines absent," "lines poor to moderate," and "lines marked" All the assessments were made by an independent radiologist who was unaware of the left auricular and pulmonary arterial pressures Illustrative radiographs are not shown, owing to difficulty in reproducing fine lung detail

PRESSURE MEASUREMENTS

Left Auricular Pressure

Tracings of the left auricular pressure have been made from patients with mitral disease considered for valvotomy since 1952 as described by Allison and Linden (1953). From each of the last 100 of these curves a mean pressure was calculated (Wiggers 1950) The pressure curve throughout a heart cycle was considered, and both its length and the area under the curve were measured The mean pressure was then derived by dividing the area by the length This is illustrated on a typical tracing in fig 1, where the base of the rectangle equals the length of the heart-cycle and the height of the rectangle is the mean pressure To balance the respiratory variation of left auricular pressure, a heart-cycle in mid-inspiration or mid-expiration was selected for measurement This mean pressure probably approximates to the average pressure at the venous end of the pulmonary capillary

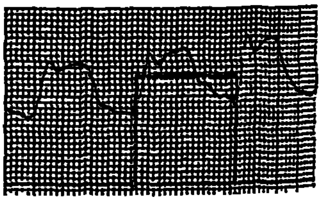

Fig 1—Tracing of left auricular pressure to illustrate method of deriving mean pressure

Pulmonary Arterial Pressure

Tracings of the pulmonary arterial pressure were obtained during the same bronchoscopy from 64 of the above 100 patients (Allison and Linden 1955) From each curve the mean pulmonary arterial pressure was calculated by adding a third of the pulse pressure to the diastolic level This value approximated closely to that obtained by integrating the pressure curve as in the determination of the mean left auricular pressure

The pulmonary arterial pressures of the 16 patients with pulmonary hypertension but without mitral disease were obtained during cardiac catheterisation, and mean pressures were again calculated from the tracings

The time interval between chest radiography and pressure recording was usually less than four weeks and never more than six months

RELATION OF LINES TO PRESSURES

The assessment of each radiograph was related to the pressures from that particular patient Thus, it was possible to relate lines to left auricular pressure in all of the 100 patients with mitral disease, and to pulmonary arterial pressure in 64 of them The association of each of these pressures was then compared with lines The 16 patients without mitral disease were included, in order to estimate the effect of pulmonary hypertension alone

The difference in pressures in the three radiographic groups of patients with mitral disease were compared statistically by Student's "t" test (Fisher 1930), conventional orders of significance being adopted Difference liable to occur less than 1 20 times by chance are described as barely significant, less than 1 100 times as moderately significant, and less than 1 1000 times as highly significant

Results

Relation between Horizontal Lines and Mean Left Auricular Pressure in 100 Patients with Mitral Disease

Lines were present on the radiographs of 63 of these patients No lines were found when the pressure was below 10 mm Hg, but they were invariably present at mean pressures exceeding 24 mm Hg The classification

TABLE III—SURVIVAL OF SINGLE STRAINS IN VARYING CONCENTRATIONS OF CHLORAMPHENICOL

Species	Original no. of organisms per loopful	Overnight sensitivity (µg per ml.) (see text)	Chloramphenicol (µg per ml. in 20% blood broth)						
			64	32	16	8	4	2	1
H. influenzæ type 1	23×10^{5}	2			3/0	3/0	4/0	5–9/<10	1 – –
H. influenzæ (non-capsulated)	33×10^{5}	1			1/0	1/0	1/0	5/0	2 – –
Pneumococcus type 1	25×10^{5}	4–8			2/0	5/0	5/0	1 – –	
Strep. pyogenes	27×10^{5}	4	3/0	5/0	5/0	5/0	3/1000	1 – –	
H. pertussis (avirulent)	45×10^{5}	4–8		9/0	14/0	14/0	2 – –	1 – –	
Strep. viridans (endocarditis)	500×10^{3}	4–8		7/0	9/0	14/12	2 – –	1 – –	
*Staph. pyogenes**	71 × 10	8	7/0	14/500	14/1000	2 – –	1 – –	1 – –	
Strep. fæcalis	35 × 10	8	9/0	14/71	7 –	2 – –	1 – –	1 – –	

Notes: 1. Standard loopful estimated at 0·007 ml.
2. Symbol of results: 2/10 = loopful yielded 10 colonies after 2 days' incubation. – = moderate multiplication. – – = free growth. 5/0 = first sterile subculture on fifth day.

* Preliminary culture in serum broth with cocci in clumps.

broth allowed little more persistence of any of the brucellæ than was observed in broth—a period of about a week. These organisms, even more than the typhoid bacillus, live and multiply intracellularly and the methods described here are of little value in their study.

Strep. fæcalis has been singled out by Dubos and many others as an unusually persistent organism, and the present work has confirmed this. It was noticed, however, that not all strains of streptococci capable of growing on bile-salt medium—a simple preliminary test for the species—were of equal hardiness: even the three selected strains quoted in table II might vary in their performance. It is still remarkable that, when plain broth was the medium, subcultures over a period of two or three weeks sometimes continued to yield almost unvarying numbers of colonies.

Table III shows the results of titration of individual strains of various species in blood broth so as to show the course of events and the relation between the overnight sensitivity and the ultimate result. The overnight sensitivity was roughly estimated, after one night's incubation, from the discoloration of the blood when free multiplication was observed. With a large inoculum, however, some effect on the blood may be seen when multiplication has been largely controlled, as with the pneumococcal bottle containing 4 µg chloramphenicol per ml. The remarkable persistence in the 2 µg bottle of *H. influenzæ* I was shown clearly in films to be associated with agglutination, when on the twelfth day the colony count was slowly increasing after a fall to one colony on the seventh day; but the clumps were small and it was obvious that sterilisation had almost been achieved. Agglutination was also observed with the four organisms which persisted longest—*H. pertussis*, *Strep. viridans*, the staphylococcus, and *Strep. fæcalis*.

An avirulent strain of *H. pertussis* was used because in this form the organism grows more freely; in blood broth multiplication was rapid. It was thought that the ability to survive bacteriostasis was likely to be associated with the species rather than with virulence. The table shows that sterilisation of the cultures was slow, and it may be added that the colony count on the third day from the bottle with 32 µg chloramphenicol per ml. was estimated at about 1000. This result, considered in conjunction with those observed in treatment (Medical Research Council 1953), suggests that, as in scrub typhus, the ultimate extermination of the infection depends on the development of immunity, but that control of bacterial multiplication during the first week (when it is at its greatest) may modify the whole course of the disease, whose later symptoms may well be due to absorption of bacterial products during the earlier period.

Strains of *Strep. viridans* isolated from endocarditis may vary considerably, not least in their rate of growth. The organism referred to in table III multiplied slowly on blood-agar and it will be seen that sterilisation was rather slow, like that of *H. pertussis*. A similar result was obtained with another slowly growing strain from a case which failed to respond to penicillin even when combined with streptomycin, but was apparently cured when chlortetracycline (aureomycin) and penicillin were given together, the latter to prevent development of resistance. A third strain, a more rapid grower, died out in a few days in 10 µg chloramphenicol per ml. It is therefore suggested that although penicillin is the drug of choice in endocarditis other antibiotics should not be ignored if the bactericidal ones fail.

Discussion

As I have explained, chloramphenicol was used in these experiments because it was the most suitable of the bacteriostatic drugs for the particular purpose. I must emphasise that the indiscriminate clinical use of this antibiotic is to be condemned because its toxic effects, though rare, are so serious that they can be discounted only in face of very serious infection, such as enteric fever or certain forms of acute meningitis for which the drug is well suited if the heavy dosage can be maintained.

The results obtained are not surprising, but they may perhaps help towards a more rational use of bacteriostatic agents. On certain bacterial species these drugs have in fact a lethal effect, though their action is probably always somewhat slower than that seen with the bactericidal group. To other species however they will not be deadly unless backed by the full inflammatory reaction of the body, which is lacking in conditions such as acute meningitis and endocarditis.

The apparent correlation between the clumping or agglutination of bacteria and their longer survival may have significance in endocarditis—a condition in which the presence of antibody may cause both agglutination and possibly a slower rate of growth, thus making the extermination of the infection more difficult. The occasional appearance of the same phenomenon in susceptible species, *H. influenzæ* and the pneumococcus, was rather startling; but if, as seems possible, the persistence of a few organisms is promoted rather than prevented by the action of antibody, this can rarely have significance in meningitis, which is unlikely to occur in an immune individual. Nevertheless the frequent recurrence of infection of these two species in chronic bronchitis after antibiotic treatment (*Lancet* 1955) would be of interest in this connection if it could be shown that a true recurrence was usual, rather than a fresh infection.

It remains open to question whether, in a scientific sense, survival under conditions of complete bacteriostasis is possible even with such a species as *Strep. fæcalis*. As is shown in table III—and this was confirmed by further experiment—the strain used (N.C.T.C. 6782) died out in 64 µg chloramphenicol per ml., persisted with little change of numbers in 32 µg, and showed multiplication in 16 µg. When bacteria occur in clumps or chains it is impossible to be sure that certain individuals are not slowly reproducing themselves while others are dying. The margin in concentration of the drug is a small

* Obtained by needle puncture during bronchoscopy
† Obtained by cardiac catheterisation

showed well marked basal horizontal lines She remained at home on medical treatment, awaiting operation, and on admission four months later a further radiograph of similar quality showed almost complete disappearance of the lines She was no longer orthopnoeic, though still dyspnoeic on exertion The left auricular pressure, measured two days before operation, showed a mean value of 17 mm Hg

This patient had a mean left auricular pressure of 17 mm Hg, associated with lines of "poor to moderate" quality If no radiograph had been taken at the time the pressure was recorded, the only available film would have been four months old and would have shown "marked" lines

Such a long time-interval was uncommon in this series, in most instances the interval was less than four weeks However, a period of medical treatment would always tend to lower the left auricular pressure, and patients in whom this occurred would have pressures lower than expected from the grade of lines shown on the radiograph taken before treatment was begun

2 Only on films of good quality can lines of "poor to moderate" degree be seen with certainty Under-penetration (accentuating the overlying soft-tissue shadows) or over-penetration (eliminating the fine detail) will each cause lines to be missed These radiographic factors may have applied to a few patients in this series These, in spite of being in the higher pressure range, would then appear in the "lines absent" group

3 The build of the individual patient sometimes caused difficulty, particularly in those female patients whose heavy breast shadows obscured the detail of the lower zones of the chest radiographs Here again, patients with left auricular pressures falling in the higher range would appear in the "lines absent" group

If the appearance of basal horizontal lines on the chest radiographs of patients with mitral disease depends on a critically raised left auricular pressure, such lines might be expected in other forms of heart disease in which pulmonary œdema occurs That they may appear in such patients is shown by the following case

A man, aged 38, was admitted to hospital in May, 1955, with a history of progressive dyspnœa on exertion for four months Chest radiographs showed basal lines of "poor to moderate" quality, and at this time the patient was orthopnoeic Myocardial infarction was diagnosed He improved slowly, and by June, 1955, he was no longer orthopnoeic, chest radiography now showed the lines to have disappeared He was discharged home, but was readmitted seventeen days later with pulmonary œdema from which he died Necropsy showed extensive myocardial and subendocardial fibrosis with one small area of recent infarction

This is one of several cases in which lines were first shown during a period of left ventricular failure such lines appear to be transient, and rarely fall in the "marked" category "Marked" lines would seem to require a high and relatively constant left auricular pressure—a state of affairs which must be unusual in disorders other than mitral disease

Finally, the relation of the lines to frank pulmonary œdema should be mentioned For pulmonary œdema to arise, the pulmonary capillary pressure must exceed the colloid osmotic pressure of the plasma protein (Hayward 1955) and tissue-fluid must pass through the alveolar walls into the alveoli themselves Parker and Weiss (1936) have shown that œdema of the interlobular septa can arise independently of alveolar transudation and that the thickness and texture of the alveolar wall plays an important part in determining whether or not alveolar transudation occurs It is reasonable to suppose that the recent appearance of lines in heart disease indicates a level of left auricular pressure not far below that necessary for production of pulmonary œdema Such recently occurring lines, therefore, are radiographic evidence of a dangerously high left auricular pressure and their appearance in a patient with mitral disease warrants early consideration of more intensive treatment including valvotomy

Summary

The chest radiographs of 100 patients with mitral disease have been examined for basal horizontal lines These were found in 63 patients, and the lines were correlated with both mean left auricular pressure and mean pulmonary arterial pressure A much closer relationship was found with the left auricular pressure than with the pulmonary artery pressure, the left auricular pressure has a dominant rôle in the production of lines

The chest radiographs of 16 patients with pulmonary hypertension arising from causes other than mitral disease were also examined 14 of these showed no lines, and the findings in this group support the view that pulmonary hypertension alone is not the cause of the lines

The recent appearance of basal horizontal lines on the chest radiographs of a patient with mitral disease indicates a dangerously high left auricular pressure, and warrants early consideration of more intensive treatment, including valvotomy

ADDENDUM

Since this paper was written Bruwer et al (1955) have presented evidence, based on determinations of pulmonary arterial and pulmonary capillary pressures recorded during cardiac catheterisation, that the pulmonary capillary pressure is the more important factor in production of lines Our conclusions accord with theirs

We are indebted to Prof A S Johnstone for his independent assessment of the radiographs, to Prof P R Allison and Mr G H Wooler of the thoracic surgical department, the General Infirmary at Leeds, for permission to study cases under their care, and Professor Allison and members of the medical professorial unit for helpful advice and criticism during the preparation of this paper

The blood vessels in *lymph nodes* and *tonsils* may be heavily involved, but this seems to be quite unusual

Rackow et al (1952) suggested *gum biopsy*, in 5 of my cases multiple sections from many samples of gum and tongue at necropsy showed lesions deep in the tongue in 1 case and in the gums in none

The heavy involvement of vessels in the portal tracts prompted Rackow et al (1952) to suggest *liver biopsy* At about the same time, Chediak et al (1952) reported typical lesions in a piece of liver obtained during splenectomy (lesions were also present in the spleen) It is likely that the risk of hæmorrhage in thrombotic microangiopathy will contra-indicate liver biopsy except at laparotomy

Muscle biopsy has been uninformative in all 7 published cases in which it was recorded (Symmers and Barrowcliff 1951, Blackman et al 1952, Chediak et al 1952, Case Records of the Massachusetts General Hospital 1952, Adelson and Stefanini 1952, Adelson et al 1954, Fisher and Creed 1955), and in 6 unpublished cases known to me, in 1 of my cases muscle biopsy showed abundant typical lesions, although skin biopsy showed none

Skin biopsy, curiously enough, has rarely been done in thrombotic microangiopathy A positive result was obtained in 1 clinically typical case of mine in which, however, necropsy was not allowed (cited by Rackow et al 1952), the result was negative in 4 unpublished cases known to me, and in the case of Adelson and Stefanini (1952) Chediak et al (1952) did not give the result of their biopsy of a hæmorrhagic nodule in the forearm—presumably in the skin

Biopsy of *bone marrow* to demonstrate the vascular lesions was suggested by Fitzgerald et al (1947) Marrow biopsy for hæmatological investigation was described in 4 cases (Altschule 1942, Engel et al 1947, Epstein et al 1948, Goldenberg et al 1950) without mention of the blood-vessels it is not clear from the reports whether the term biopsy was used in these cases to describe films of marrow obtained by aspiration, or conventional histological examination of excised specimens Hæmatological examination of films of aspirated marrow has, of course, been recorded in many cases Cooper et al (1952) demonstrated thrombotic microangiopathy in paraffin sections of particles obtained by aspiration of bone-marrow in their 2 cases, the only other workers to adopt this procedure did not find vascular lesions in their case (Green and Green 1953) A high proportion of marrows examined post mortem in cases of thrombotic microangiopathy has shown the characteristic lesions, bone-marrow is probably second only to liver among tissues accessible to biopsy which are likely to contain diagnostic lesions Marrow biopsy may, therefore, prove of value, contrary to what is suggested by the few published observations

In contrast to the disappointing results of biopsy, there are 10 reports of finding the diagnostic lesions in *spleens* removed therapeutically

Splenectomy has been done during the course of the illness in 12 cases, in 2 the splenic vessels were not mentioned (Engel et al 1947, Ritama and Virkkunen 1953), but in all the others typical lesions of thrombotic microangiopathy were found (Baehr et al 1936, Muirhead et al 1948, Green and Rosenthal 1949, Gardner et al 1951 [case 2—see Singer 1954], Meacham et al 1951, Chediak et al 1952, Tacket and Jones 1952, Barondess 1952, Adelson et al 1954) In most of these cases the patient died shortly after operation

Careful histological study of every spleen removed in cases of hæmatological disorders may reveal unsuspected cases of thrombotic microangiopathy, the central arterioles and trabecular vessels are those likeliest to show the diagnostic lesions

The possible value of biopsy in the diagnosis of this disease requires further investigation *Rib biopsy* may prove to be the procedure of choice, and could be combined with biopsy of skin and muscle through the same incision

Rib biopsy demands particular care by the pathologist, when preparing the specimen, to reduce to the minimum the delay occasioned by decalcification, careful dissection is necessary because the thrombotic lesions are most numerous in the zone of the marrow cavity immediately beneath the cortex

The increasing accuracy of diagnosis in thrombotic microangiopathy has not so far had any material effect on the treatment of this mortal disease, nor has it added much to our knowledge of its nature This may be because diagnosis has usually been made at a late stage Biopsy done early in the course of any illness which presents unexplained hæmolytic anæmia, thrombocytopenia, or neurological disturbances offers the only means as yet known by which thrombotic microangiopathy can be recognised early enough to allow full investigation into its nature and treatment In 2 of the cases reported here diagnostic lesions were present for some time before the usual clinical manifestations developed Since not all cases run a fulminating course, even when the components of the tetrad begin to appear, there is some slight hope that biopsy immediately after the diagnosis is first suspected may give valuable time for investigation and treatment

Treatment

Until we understand the cause and nature of thrombotic microangiopathy, treatment can only be empirical Blood and platelet transfusions, splenectomy, sulphonamides, antibiotics, cortisone, corticotrophin, vitamins, and heparin have so far had no important influence on the course of the illness, except apparently in 2 cases, reported by Gardner et al (1951) (whose 2nd patient lived for nine months after splenectomy) and by Meacham et al (1951) (1 of whose patients had a remission lasting for over two years after splenectomy)

Case-reports

In the following 3 cases of thrombotic microangiopathy, the characteristic histological lesions were unexpectedly found before any clinical manifestations appeared The correct diagnosis was made at this stage in the first 2 cases, the lesions were not recognised until later in the 3rd case

PRESENTING WITH LYMPHADENOPATHY

Case 1 —A man aged 47, while living in England in 1953 began to show generalised enlargement of his superficial lymph nodes, without other symptoms His health had previously been good, apart from mild typhoid fever in 1942 He had been inoculated with typhoid paratyphoid vaccines several times while serving in the Afrika Korps A year before the typhoid infection his spleen was ruptured when a depth charge exploded nearby while he was swimming, his spleen was removed He had never had any chemotherapy or treatment with antibiotics

On examination three weeks after the nodes were first noticed the only abnormal findings were discrete, slightly tender nodes, up to 2 5 cm in diameter, in the neck, axillæ, and groins He had no fever

Investigations —Chest radiograph normal Urine normal Blood count red cells 5,100,000 per c mm, Hb 14 9 g per 100 ml, white cells 8600 per c mm (normal differential count), platelets in normal numbers in blood films Paul-Bunnell reaction negative Agglutination reactions (salmonellæ, shigellæ, brucellæ) were consistent with former T A B vaccination and typhoid fever, but otherwise negative Wassermann and Kahn tests negative Mantoux reaction positive (1 1000) Serum albumin level 3 4 g and serum-globulin level 3 3 g per 100 ml Erythrocyte sedimentation rate (E S R) 28 mm in first hour (Westergren)

Axillary lymph node biopsy —Sections showed simple reactive hyperplasia of the lymphoid follicles, many small arterioles and capillaries showed changes typical of thrombotic microangiopathy

TABLE I—MAIN DIFFERENCE BETWEEN LONG TERM AND SHORT TERM TREATED CASES

Treatment	Patients who have been in hospital last 30 days or more before delivery (%)	Average length of treatment in hospital just before delivery (days)
Long term	78	45
Short term	*10*	*15*

calculated term and treated in the hospital on average for the last 45 days before delivery, whereas the short-term group was admitted to hospital on the 35th day and treated for only the last 15 days The treatment, however, both medical and obstetrical, is the same in the two groups

Severity and Complications of Diabetes

Table II shows the severity and complications of diabetes and the number of primiparæ in the material of 1946–53 The diabetics are classified according to the system of White (1949) We have been forced to omit her group E because we have no information about the state of our patients' pelvic arteries About two thirds of the cases were severe (White's classes C–F), and our material, like White's, differs in this respect from most other material, which does not contain so high a proportion of severe cases

Short-term Group as Control

Table II shows that there is no major difference between the long-term and the short-term groups as regards severity and complications of diabetes, and, as already mentioned, all the patients are treated in the same way obstetrically and medically Only one factor varies—the duration of treatment So our material is well suited for research into the significance of the strict medical treatment in a hospital for a long time compared with a short time during the later part of pregnancy (table I)

Fœtal Mortality

The fœtal mortality (stillbirths and neonatal deaths within 10 days after delivery) of babies weighing 1000 g (2 lb 3 oz) or more is shown in tables III–V We have only a very few early abortions, spontaneous as well as induced, because such cases are admitted to other hospitals On the other hand, our puerperæ with their infants are routinely transferred to their homes (or other hospitals) on the 10th day after delivery

TABLE II—SEVERITY AND COMPLICATIONS OF DIABETES AND FREQUENCY OF PRIMIPARÆ IN LONG TERM AND SHORT TERM TREATED DIABETICS (1946–53)

—	No of cases (%)	Long term treated (%)	Short term treated (%)
White's classes			
C D, and F	64	65	62
D and F	32	33	32
Diabetic retinitis	23	26	21
Diabetic nephropathy (pyelonephritis)	24	28	22
Calcified arteries	5	8	4
Primiparæ	44	37	49

In 1926–45, before the introduction of the strict treatment, the over all fœtal mortality was 38% (table III) Since then this mortality has decreased to 27% (1946–52) and 15% (1953–55) The first decline from 38% to 27% was due to the introduction of the long-term group, in which the mortality was only 12%, whereas the fœtal mortality in the short term group (36%) remained unaltered The further drop in the total fœtal loss to 15% was mainly due to the fact that an increasing proportion of cases were long term and to small decreases in the fœtal mortalities—in the long term group to 8% and in the short term group to 27% The fœtal mortality in the long term group was about a third of that in the short-term group in both 1946–52 and 1953–55 Table IV shows that the difference of the mortalities, with a ratio about 1 3, holds good in several subdivisions of the material

The mortality in the short term group was due partly to pre coma or to other forms of gross neglect relatively early in pregnancy, further to death in utero or to early delivery for conditions—e g, malformations—which could not have been cured even by the most strict supervision and treatment Table V shows that such conditions are not the main cause of the difference in mortalities In the babies weighing at birth 1600 g ($3^1/_2$ lb) or more and alive at the onset of labour there was still a difference of 1 3 in the mortalities (6% in the long-term treated cases and 17% in the short term treated cases) In the total material of 122 infants born alive to long-term treated diabetics the neonatal mortality was 5 (4%), such a baby very seldom dies *in the neonatal period*

TABLE III—FŒTAL MORTALITY * FROM 1926 TO SEPT 30, 1955, CLASSIFIED BY TREATMENT IN 422 BABIES

Period	Treatment					
	Long term		Short term		Total	
	No of babies	Fœtal loss	No of babies	Fœtal loss	No of babies	Fœtal loss
1926–45	—	—	—	—	157	59 (*38%*)
1946–52	58	7 (*12%*)	94	34 (*36%*)	152	41 (*27%*)
1953–55	72	6 (*8%*)	41	11 (*27%*)	113	17 (*15%*)

* Stillbirths and deaths in first 10 neonatal days of babies weighing at least 1000 g (2 lb 3 oz) at birth

2 mothers died, but none in the last eighteen years

How much can we hope to reduce this fœtal mortality? In our total series major congenital malformations leading to the baby's death before the 11th postnatal day amounted to about 3% Moreover the perinatal mortality in Copenhagen is about 3% (Kærn 1955) (Perinatal deaths comprise stillbirths and deaths in the first week after birth of infants weighing at least *1000 g*) So perhaps a fœtal mortality of about 6% in pregnancy in diabetics might not be far from the mark

Classification of Risk to Fœtus

To estimate the risk to the fœtus we use the well known classification of White (1949) In our 1946–55 *material of 265 cases 13 belong to class A* with no fœtal mortality and 10 to class F with a fœtal mortality of 50% Although the number of cases is small, this fits perfectly with White's classification But table VI shows no pattern in mortalities of classes B, C, and D either in the long term group (this might be due to our treatment) or in the short term group We feel that White's classification is a good one although not entirely satisfactory—Oakley (1953) thinks the same—but we have not yet succeeded in devising a better one

Comparison with Other Treatments

It is appropriate to compare the results of our treatment with those of White (1949) and White et al (1953) from the Joslin Clinic in Boston, those of Peel and Oakley (1949), Oakley (1953), and Peel (1954) in London, and the report to the Medical Research Council (1955)

As is well known, White and her colleagues are the pioneers in this field and have reported the largest personal series (White et al 1953) and lowest fœtal mortality so far (10%) White's treatment consists in (1) treatment of diabetes to achieve the best possible blood cell morphology, osmotic and mechanical erythrocyte fragility tests, hæmoglobin level, and E.S.R. were all repeatedly within normal limits No hæmolysins or erythrocyte or platelet agglutinins were demonstrated. Wassermann and Kahn tests were negative Cerebrospinal fluid (C.S.F.) normal. Serum chemistry, kidney and liver function tests and urine normal, radiographs of chest and air encephalographs normal, electro encephalographs normal.

Two weeks after admission the patient went home, against medical advice

Second admission —Three days after discharge the patient was readmitted in a hypomanic state (There was no history of previous mental disturbance) After sedation she was found to have left hemiparesis, right facial twitching and choreo-athetoid movements of the right arm Next day the mental symptoms had disappeared, and the only neurological abnormalities were a left abducens palsy and some incoordination of fine limb movements There was a slightly puffy erythema of the forehead nose and cheeks Symmetrical, linear ecchymoses had formed in the skin below the breasts and across the scapulæ where her bust-bodice was tight and a few petechiæ developed under the sphygmomanometer cuff when her blood-pressure (120/70 mm. Hg) was measured No other clinical abnormalities were found and her temperature was normal Two days later she felt and looked ill, and her condition began to deteriorate Fever developed, and continued until she died, with a daily temperature range of 100–102 4°F On some days the tip of the spleen was felt Neurological abnormalities disappeared, except for persistent exaggeration of the left patellar and ankle reflexes, and a left extensor plantar response

Further investigations and course—The red-cell count and hæmoglobin level fell from 3,800,000 per c.mm. and 10 4 g per 100 ml. on readmission to 2,000,000 per c mm. and 5 0 g per 100 ml two weeks later, after which the anæmia remained stationary The white-cell counts remained about 9000 per c.mm, with about 6000 neutrophils No immature red or white cells were seen in the peripheral blood, reticulocyte-counts were between 10 and 18% Platelet-counts ranged between 20,000 and 250,000 per c.mm., with rapid variation throughout the illness, although the count was often below the "critical level" (40,000 per c mm.) there was no purpura or further bruising, and no more petechiæ were found when the blood-pressure was taken. L.E. cells repeatedly sought without success Blood-cultures sterile Agglutination reactions (salmonellæ, shigellæ, brucellæ, leptospiræ) negative Jaundice appeared on the fourth day and increased with the anæmia Urine trace of protein, excess urobilinogen but no bilirubin, a few red cells. Cortisone (300 mg daily) and aureomycin were given from the day of readmission, without effect Repeated transfusions of fresh blood through silicone-treated apparatus did not influence the anæmia or the platelet-count the variations in which were independent of the treatment A fortnight after readmission the patient began to have hallucinations and went into a withdrawn, schizoid state Choreiform movements and other transitory neurological abnormalities recurred, and her general condition deteriorated rapidly Cortisone was administered in diminishing doses over four days, and was then discontinued The patient began to have severe headaches, the retinæ and C.S.F. were normal. There was frank hæmaturia once The blood-urea level rose to 108 mg per 100 ml. and urinary output fell The blood-pressure remained normal Seven weeks after the initial fit she collapsed with sudden abdominal pain and rapidly deepening shock, and she died an hour later while being prepared for laparotomy

Necropsy—Many hæmorrhagic ulcers in the jejunum and ileum, one ulcer had perforated, flooding the abdominal cavity with intestinal contents and blood Scattered serosal petechiæ. Pale, tough vegetations, up to 0 4 cm. in diameter, on mitral cusps cultures of these were sterile Spleen (weight 200 g) and all other organs appeared healthy

Histological examination showed thrombotic microangiopathy in most organs, particularly the myocardium, adrenals, liver (fig 2), brain, bone-marrow and myometrium, the lesions were scanty in ovaries, uterine tubes, stomach, colon, and kidneys, and were not found in skin, skeletal muscle, or lymph nodes The mitral vegetations had the histological appearances of verrucose endocardiopathy (Libman-Sacks disease)

This patient's history included 3 features of possible ætiological significance (1) sensitisation to sulphonamides, (2) throat infection three weeks before the acute illness and (3) onset of symptoms while sunbathing

Sensitisation has been noted in other cases of thrombotic microangiopathy—to sulphonamides (Engel et al 1947, Fitzgerald et al 1947) penicillin (Gendel et al 1952), oxophenarsine (Symmers 1956), formaldehyde (Clinicopathologic Conference 1951), and adhesive tape (Bernheim 1943) The significance of such sensitisation is not clear

A recent *acute infection*, usually of the upper respiratory tract, has been noted in several cases

Laszlo et al (1955) described a case in which the illness developed after some weeks of *sunbathing*, the clinical manifestations suggested disseminated lupus erythematosus, and L.E. cells were found.

L.E. cells were sought unsuccessfully in 9 cases including the present one (Gendel et al 1952 Case Records of the Massachusetts General Hospital 1952 Barondess 1952 Cooper et al 1952 Green and Green 1953, Vannucchi and Doni 1953, 1954 Clinicopathologic Conference 1955) Skin changes resembling lupus erythematosus were observed by Gendel et al (1952) as in this case Abnormalities of porphyrin metabolism were present in 1 case (Clinicopathologic Conference 1951) and were absent in the present one Verrucose endocardiopathy was reported in 10 previous cases (Baehr et al 1936, Engel et al 1947, Meacham et al 1951, Gendel et al 1952, Barondess 1952, Vassar and Spain 1953) this is interesting because it supports the possibility of a relation between thrombotic microangiopathy and disseminated lupus erythematosus and other "collagen diseases" (Symmers 1953, Laszlo et al 1955) Menorrhagia has been noted in 4 other cases (Fitzgerald et al 1947, Blackman et al 1952, Radnai et al. 1954) and metrorrhagia in 5 (Muirhead et al 1948, Epstein et al 1948, Green and Rosenthal 1949, Ellison and Lloyd 1954, Stuart and MacGregor-Robertson 1956) The absence of purpura in this case is particularly striking in view of the repeated finding of platelet-counts well below the "critical level" Intestinal perforation, the immediate cause of death in this case has not been described before in thrombotic microangiopathy

PRESENTING WITH ABDOMINAL PAIN

Case 3 —A previously healthy girl, aged 15 while at school, had a sudden sharp pain in the right iliac fossa and vomited The pain lasted for a few seconds only, and was followed by a persistent dull ache in the hypogastrium. Her doctor saw her a few hours later Because her periods had occurred regularly every thirty days since their onset two years earlier, and she was at mid-cycle, he considered that the pain was caused by the bursting of an ovarian follicle, however, there was tenderness in the right iliac fossa, and he sent her to hospital

On admission his diagnosis was confirmed by the finding of a hæmatoma in the right ovary, with a blood-clot protruding from it and blood in the pelvis, examination of the rest of the abdominal cavity showed no abnormality except wide-

Fig 3—Thrombotic microangiopathy in myocardium in case 3. (Hæmatoxylin and eosin × 250)

Effect of Long-term Treatment

We are convinced that the decrease in total fœtal mortality in our series through years is due to our long-term treatment Although expert obstetrical management is a *conditio sine qua non*, the main credit goes to the treatment during pregnancy, because the long term and the short term cases have had the same obstetrical care during delivery

The main factors in our treatment are treatment by one physician, confinement to hospital for several weeks, and keeping down the blood-sugar level The "one physician close supervision" during the last months of pregnancy seems to be necessary to get a low fœtal mortality As regards confinement to hospital we have to admit that, although treatment in hospital for a long period has been shown here to be superior to treatment for a short time, we have not tried to prove that such a period of treatment in hospital is superior to very close personal supervision of an ambulant patient (cf White 1949)

Clearly, methods including close supervision of the pregnant will decrease the number of cases with precoma, lead to early treatment of toxæmia and other complications, and thus lower the fœtal mortality In addition our long-term treatment has a strong effect on the baby the long term treated baby has a higher blood sugar level (Pedersen 1952, Pedersen et al 1954) and is smaller (Pedersen 1954b), the amount of amniotic fluid is smaller (Pedersen and Jørgensen 1954), and the long term treated baby withstands labour better than does the short-term treated baby On all points so far examined the long-term treated babies are more like normal babies In contrast to this, the number of complications during delivery and the number of obstetrical procedures has not decreased in the long-term treated mothers compared with the short-term treated mothers (unpublished) The effect on the baby seems to be due either to the lowering of the mother's blood sugar level for a long time or to unknown factors favourably influenced by this strict control of the diabetes—a control which can hardly be achieved outside a hospital

We must conclude that the long-term treatment is a prophylactic procedure whose effect is to make the babies more like normal babies in different ways At present we cannot tell exactly which mechanisms are involved, except that the metabolism of the fœtus must be more normal (Pedersen 1952)

Summary

The long term treatment of pregnant diabetics is described

By applying this treatment to 130 cases in 1946–55 the fœtal mortality was reduced to 10%, whereas in 135 short term controls it was 33%, compared with 38% in 157 cases in 1926–45

The total fœtal mortality in 265 cases in 1946–55 is steadily decreasing but varies according to the proportion of long term to short term treated cases

At present, in the material of 1953–55, the total fœtal mortality is 15% in 113 cases, 64% of the cases belong to the long-term treated group and have a fœtal mortality of 8% In these last 113 cases 17 cæsarean sections were done (15%)

Theoretically the lowest fœtal mortality achievable is at present about 6%

To get a low fœtal mortality it is necessary to give intense medical treatment by one or a few doctors during pregnancy and to have access to one or a few expert obstetricians It is unnecessary to give sex hormones or to do many cæsarean sections

Our treatment is prophylactic, making the babies more like normal babies in different ways, especially as regards neonatal blood sugar level, weight and length, volume of liquor amnii, and fœtal mortality

VITAMIN-A LEVELS IN IDIOPATHIC HYPERCALCÆMIA

W Morton Fyfe
M B Glasg, M R C P, M R C P E, F R F P S, D C H
SENIOR REGISTRAR IN PÆDIATRICS,
ROYAL HOSPITAL FOR SICK CHILDREN, YORKHILL, GLASGOW

The ætiology of the syndrome described by Lightwood (1952) as "idiopathic hypercalcæmia in infants with failure to thrive" is unknown, but it has been suggested that intolerance of vitamin D is the cause (Hutchison 1955) In view of the close association of vitamin A with vitamin D in nature, the plasma vitamin A levels in this syndrome were studied as part of an investigation into vitamin-A metabolism in infancy

Material and Methods

The plasma vitamin A levels of 7 healthy children, 5 marasmic infants, and 8 infants with idiopathic hypercalcæmia were estimated before (fasting levels) and four hours after a large oral dose of vitamin A 2 of the infants with idiopathic hypercalcæmia (cases 11 and 13) also had renal acidosis The preparation of vitamin A used was synthetic vitamin-A palmitate in arachis oil ('Avoleum,' B D H) The dose administered was 12,500 international units (I U) per kg of body weight up to a maximum of 250,000 I U One infant with idiopathic hypercalcæmia (case 12), however, was given 20,000 I U per kg of body-weight In a further 10 healthy children only the fasting plasma vitamin A levels were estimated The patients received their ordinary diets, but no patient was given vitamin A concentrates for at least forty-eight hours before the date on which the estimations were made The term "fasting" has been applied to the plasma vitamin A

TABLE I—PLASMA VITAMIN-A LEVELS IN HEALTHY CHILDREN

Child no	Age	Weight (kg)	Plasma vitamin A (I U per 100 ml) Fasting (duplicates)		4 hours after the standard oral dose of vitamin A (duplicates) *	
1	3 mos	4 9	160	—	605	605
2	4 mos	7 3	130	—	805	—
3	15 mos	14 6	120	120	195	180
4	3 yr	15 3	200	—	500	530
5	4 yr	15 0	70	120	1250	1260

17	10 yr	—	100	110	—	—

* The standard oral dose of vitamin A was 12 500 I U of vitamin A palmitate in arachis oil per kg of body weight up to a maximum of 250 000 I U of vitamin A

CLOSED TRAUMATIC LESIONS OF THE AXILLARY AND BRACHIAL ARTERIES

C. G. ROB
M.C., M.A., M.Chir. Camb., F.R.C.S.
PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON, AT ST. MARY'S HOSPITAL MEDICAL SCHOOL

A. STANDEVEN
M.A., M.Chir. Camb., F.R.C.S.E.
RESEARCH FELLOW, ST. MARY'S HOSPITAL MEDICAL SCHOOL

IN three years we have seen 8 patients in whom closed injuries led to serious lesions of the axillary brachial artery. Since few such cases have been published, we report them here.

Injury by Axillary Crutch

This group comprises 3 cases of thrombosis and 1 of aneurysm of the axillary artery. 6 cases of thrombosis from this cause have previously been published.

Platt (1930) described 2 examples, in men aged 38 and 46, both of whom had used axillary crutches from early childhood and eventually recovered full function of the limb without active treatment on changing to an elbow crutch.

The patient of Leriche and Stricker (1929) lost two fingers from gangrene before Leriche did an arteriectomy, removing 10 cm. of the artery; two years later the patient was free from pain and vasomotor symptoms.

In the cases described by Ryle (1922) and by Souques and Terris (1924) the outcome was not stated.

The present cases illustrate the symptoms and varying course of the condition.

Case 1.—A man, aged 56, who had used a left axillary crutch since an above knee amputation of the left leg in 1907, was admitted on Dec. 11, 1954, complaining of numbness of the left hand and pain in the left forearm. Nine days previously he had wakened at 1 A.M. with tingling, numbness, and loss of power of the left hand, which had been normal the previous evening, though earlier in the day he had knocked it against the door of a railway coach. He noticed in the left forearm a dull aching pain which subsequently he found to be aggravated by use and relieved partially by rest with the limb dependent.

On examination his left hand was cold and pale, with no œdema and no distension of the superficial veins. He was barely able to flex or extend the fingers or wrist against gravity, though the power of elbow movements was little less than normal. Sensation to light touch and to pinprick was reduced over the whole limb below the elbow. The left axillary pulse was easily palpable as far as the posterior fold of the axilla, below which the artery could be felt as a pulseless thickened cord. The radial and ulnar arteries were impalpable. The pulse-rate was 80, blood-pressure 160/90 mm. Hg, and the heart clinically normal. All pulses in the right limbs and the left femoral pulse were normal and the vessel walls not thickened. The Wassermann reaction and Harris tests were negative. The diagnosis of axillary artery thrombosis was confirmed by arteriography, which showed 4½ inches of artery to be occluded.

Operation.—On Dec. 20, 1954, left sympathetic ganglionectomy was done, the lower half of the stellate ganglion and the chain to below the 3rd thoracic ganglion being removed.

Postoperatively the left hand became warm and of normal colour. The patient was provided with an elbow crutch and warned against using the axillary one. Nevertheless, in view of the difficulty of using an elbow crutch with a weakened hand, he had continued to do so. On Jan. 28, 1955, pulsation was first detected in the brachial and radial arteries, though he complained still of numbness and weakness of the hand and hypoæsthesia persisted below the wrist. In August he reported the return of normal sensation and no colour changes, but still some weakness of his hand.

Case 2.—A man, aged 54, had used a right axillary crutch for as long as he could remember after poliomyelitis in early childhood. He consulted his doctor for an attack of sudden pain in the right forearm and hand, associated with coldness, numbness, and loss of power of the limb.

On examination no arterial pulse was felt below the axilla, and the limb showed the appearance of threatened gangrene.

Operation.—Upper thoracic sympathetic ganglionectomy was done, and gradual recovery ensued. The patient is now symptom-free and following his normal occupation of book-binding.

These two patients illustrate sudden complete occlusion of the axillary artery after the use of an axillary crutch. In neither was there overt evidence of generalised arterial disease or any evidence of embolism.

Case 3.—A man, aged 57, with bilateral flaccid paralysis of the lower limbs since the age of 6 months, had used axillary crutches from early childhood. In January, 1953, he noticed in his right hand tingling and numbness, which became gradually worse. In February he developed pain in the right forearm and noticed that his fingers went white on raising his arm to the horizontal, and that the radial pulse was absent, with thickening along the course of the vessel. He was seen by a physician, who confirmed the diagnosis of thrombosis of the radial artery; above this the pulsation was normal. He was given tolazoline and nicotinic acid. By early May the thrombosis had extended upwards to the brachial artery, and he complained of pain at rest in his finger-tips. Anticoagulant therapy was started, and he was transferred to St. Mary's Hospital.

On admission he said that he could not sleep for pain unless his arm was hanging down. His right hand was pale and cold, and severe ischæmic muscle pains developed in his forearm on the slightest exercise of his fingers. His right axillary pulse was strong, but the brachial pulse ceased abruptly in the middle of the arm, below which the artery was palpable as a thickened cord. The pulses on the left side were normal, but the arterial walls were thickened though not tortuous. The reactive hyperæmic flush reached the level of the metacarpophalangeal joint 22 sec., and the finger-tips 46 sec., after release of the occluding cuff, compared with 3 and 5 sec. respectively on the normal side.

Operation.—Sympathetic ganglionectomy, removing the stellate ganglion and the chain to below the second thoracic ganglion, was done on May 19, 1953. This relieved the rest pain at once, and the hand became much warmer, but there was little improvement in the ischæmic muscle pain. On May 30, 1953, the thrombosis had extended up to the third part of the axillary artery, and when shaving he was compelled by ischæmic pain to stop every minute to lower his arm to his side.

Follow-up.—He was seen in September, 1955, when he was symptom-free at rest and could write, type, and play the piano without pain but developed ischæmic muscle pain if he shook a bottle vigorously (he is a dispenser). Pulsation has not returned at the elbow or the wrist.

The sequence of events in this patient is thought to be damage to the axillary artery by his crutch leading to partial occlusion of the vessel; subsequent breaking free of an embolus, which lodged in the radial artery and caused the initial symptoms; followed by ascending thrombosis, which eventually reached the site of the original abnormality in the axillary artery.

Case 4.—A woman, aged 58, with congenital hypoplasia of the right leg, had used since the age of 3 years a single unpadded axillary crutch made by her father and renewed as required. In January, 1954, she noticed in her right axilla a small swelling which her doctor considered to be of no significance. On March 8, 1955, she developed a sudden severe pain in her right arm from the shoulder downwards, and her hand and fingers became numb, cold, white, and powerless. She had no treatment other than rest, and a month later the pain had passed off, she could do her housework, and her hand was no longer white but was still so cold that she used to warm it on the teapot.

On examination in May, 1955, arteriography showed a fusiform aneurysm of the lower axillary artery and recanalisation of an occlusion of the brachial artery at the elbow. The ulnar artery was carrying most of the forearm circulation, and the radial artery filled poorly.

On admission on June 7, 1955, she said she was symptom-free. All the pulses were present in the right upper limb, though the radial was weaker than its fellow. The aneurysm was easily palpable, and she said that this was the lump she had noticed in 1954. Her hands were of normal colour, and show that vitamin-A metabolism is abnormal in idiopathic hypercalcæmia

I wish to thank Prof Stanley Graham and Dr J H Hutchison for much helpful advice and criticism and for permission to study patients treated in their wards, Mr W M Dennison for permission to study patients treated in his wards, Dr Ellis C Wilson, in whose laboratory this work was done, for his interest and helpful advice, and Dr R A Robb, of the mathematics department of the University of Glasgow, for the statistical calculations

POTASSIUM-CHLORATE POISONING WITH OLIGURIA

TREATED BY THE BULL RÉGIME

PAGET DAVIES
M B Lond, M R C P
LATE HOUSE PHYSICIAN, CENTRAL MIDDLESEX HOSPITAL, LONDON

IN 1882 Riess noticed unusual globules and granules in the erythrocytes of a patient who died of renal failure after swallowing about 30 g of potassium chlorate Similar bodies were described by Heinz (1890) in animals poisoned with acetylphenylhydrazine

Potassium chlorate is still used medicinally as a local antiseptic, either as a solution or as lozenges for sore throats and oral ulcers Poisoning is rare nowadays but may follow a single large dose or repeated small doses

Witthaus (1911) collected 143 examples, of which 116 were fatal He noted that poisoning was usually accidental, but he recorded 15 examples of suicide, of which 2 may have been accidental, and 3 of homicide

Cochrane and Smith (1940) reported a patient with nephritis who died of renal failure following ingestion over three days of 30–35 g of potassium chlorate dispensed in error for potassium chloride

Gordon and Brown (1947) described yet another example in which death was due to renal failure

A R Cushny (Grollman and Slaughter 1947) noted that death in subacute poisoning resulted from renal failure

The following example illustrates the toxic effects of potassium chlorate and the value of the Bull régime in the treatment of the associated oliguria

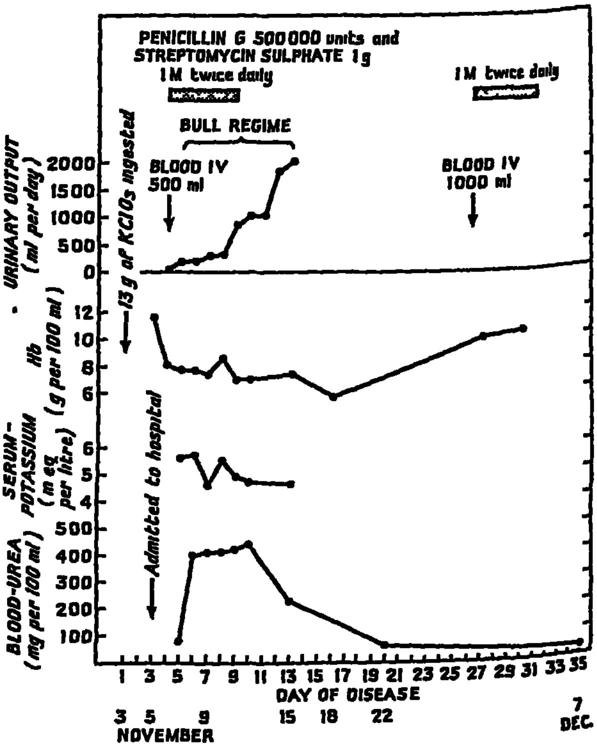
Case-report

A caretaker, aged 54, with a past history of chronic bronchitis, was admitted to hospital on Nov 5, 1954 Two days previously a frænal ulcer had developed to which he had applied during an hour or so about 13 g of potassium chlorate This he had obtained from his chemist He had not followed the pharmacist's instructions to wash out his mouth and had swallowed the crystals The same night anorexia, nausea, and a burning retrosternal pain developed He noticed that he was blue and that his urine and stools were dark There was no past history of jaundice, but he had been a moderately heavy drinker of spirits and beer

On admission he was ill, with signs of acute bronchitis and pyrexia (99°F) There was no trace of the frænal ulcer, but there was gross pyorrhœa He was jaundiced but not cyanosed, and his liver was enlarged to the umbilicus and tender His spleen was impalpable, and there was no purpura Clinically the cardiovascular and nervous systems appeared to be normal (blood pressure 130/85 mm Hg)

Laboratory Investigations—Examination of his blood showed Hb 11 5 g per 100 ml and leucocytes 30,000 per c mm (neutrophils 92%) Abnormal leucocytes were not seen The erythrocytes showed bizarre fragmentation, considerable polychromasia, and numerous Heinz bodies in wet preparations Spectroscopy of the serum showed an absorption band at 624 mμ typical of methæmalbumin, and Schumm's test showed the formation of a hæmochromogen with an absorption band at 558 mμ The serum bilirubin level was 5 mg per 100 ml The urine contained a moderate amount of protein, scanty red and white cells, numerous granular and cellular casts, and traces of hæm pigments, bilirubin, and urobilin These various features pointed to a Heinz body hæmolytic anæmia due to potassium chlorate

Treatment and Progress—The severe coincident bronchitis responded satisfactorily to a five day course of penicillin G 500,000 units daily and streptomycin sulphate 1 g given intramuscularly twice daily Twenty four hours after admission oliguria developed, which was treated with the protein free high calorie diet of Borst (1948) and Bull and Joekes (1949) Through an intragastric tube an emulsion of 100 ml of arachis oil in a litre of 40% glucose with gum acacia q s was given daily Fluid equivalent to the previous day's output of urine and vomit was added Intravenous therapy was not attempted, and neither alkalis nor potassium salts were given by mouth Vitamin B complex was given as 'Becosyn' 2 ml intramuscularly daily, and special attention paid to oral hygiene For the next few days the patient remained very ill with persisting oliguria and jaundice (see table and figure) Intravascular hæmolysis continued, and his Hb decreased from 11 5 g to 7 9 g per 100 ml in the first twenty four hours following admission Next day he was therefore given a transfusion of 1 pint of stored blood from which the plasma (and in it much of the red cell potassium) had been removed An electrocardiogram on the following day did not show any evidence of hyperkalæmia For several days his condition remained critical He continued to vomit, and his blood urea level rose to over 400 mg per 100 ml, but his electrolyte balance remained satisfactory, and his jaundice began to fade about the seventh day of the illness The urinary output rose steadily, and on the thirteenth day the intragastric drip was discontinued By then the jaundice had gone and liver function tests were normal On the sixteenth day the liver edge was no longer palpable and urinalysis was



Blood analysis and urinary output.

collateral vessels as quickly and as much as possible They can be achieved by a course of anticoagulants, by the reflex dilatation of the vessels by heating the body and unaffected limbs; and by prescribing vasodilators of which we believe that alcohol is the best Meanwhile the affected limb is kept cool and at rest (not raised) to reduce its oxygen requirements

Should the patient not be seen until several days or weeks have elapsed, further thrombosis is unlikely, and we believe that sympathetic ganglionectomy is the best treatment at this stage, for, though gangrene is unlikely and useful recovery will usually take place in time, releasing the collateral vessels from vasomotor tone appears to hasten the process

There remains the place of a direct attack on the occlusion Gask (1913) attempted the operation of thrombo endarterectomy of an occluded axillary artery of thirty seven hours' duration He succeeded in re-establishing the blood-flow, but the operation failed because clot re formed almost immediately on the arterial suture line More recent experience has shown that this operation is likely to be successful only in larger vessels

If operation is required for some complicating condition (as in case 7), or if the patient is a young manual worker, an attempt can be made to restore the normal channel by excision of the affected segment, followed by either end to-end anastomosis or the insertion of a blood-vessel graft

Summary

8 cases of occlusion of the main upper limb artery due to closed trauma are described

The natural history of the condition is shown, and the aims and methods of treatment are outlined

ADMINISTRATION OF IRON IN ANTENATAL CLINICS

W Edgar
M B Edin, D.P H, D C H
DEPUTY MEDICAL OFFICER OF HEALTH, LUTON, BEDS

H M Rice
M D Lond
DIRECTOR, PATHOLOGY DEPARTMENT, GENERAL HOSPITAL, NOTTINGHAM

PREGNANCY is a physiological state and should have no pathological effect on the hæmopoietic system of a normal healthy woman receiving an adequate diet Nevertheless, to meet the requirements of the growing fœtus, adjustments in the hæmopoietic system are necessary, and of these the most important is an increase in the blood volume (Dieckmann and Wegner 1934, Roscoe and Donaldson 1946, Berlin et al 1953) This increase is not uniform whereas the plasma is increased by about 25%, the red cells and hæmoglobin are increased by only 12–13% (Roscoe and Donaldson 1946, McLennan and Thoun 1948) The disproportionate increase in plasma often causes the Hb level to fall progressively as pregnancy advances between the 26th and 36th weeks of pregnancy the Hb level and red-cell count may be diminished by as much as 15% (Whitby and Britton 1953)

These changes, often called the hydræmia of pregnancy, have long been regarded as physiological, without any general agreement upon the definition of normal limits Various workers have defined different minimal normal values A red-cell count as low as 3,360,000 per c mm, a Hb level of 10 g per 100 ml and a packed cell volume of 33% have been suggested by Adair et al (1936)

These blood changes are associated not only with an increase in blood volume but also with a deficient intake of iron (Young et al 1946, Cartwright and Wintrobe 1949, Scott and Govan 1949, Ventura and Klopper 1951, Benstead and Theobald 1952, Davis and Jennison 1954, Fisher and Biggs 1955)

The iron requirements in pregnancy are known to be considerable McCance and Widdowson (1946) found that the daily amount of iron needed by the pregnant woman was 16–20 mg, and Neuweiler (1938) estimated that the growing fœtus requires some 375 mg of iron These requirements may not always be fully met from the ordinary diet, which has been shown by Bransby and Magee (1947) to be close to iron starvation

Present Investigation

The aims of the investigation were to determine the following facts in routine antenatal clinic practice

(1) How far the blood changes associated with the hydræmia of pregnancy can be prevented by the daily administration of a small dose of iron

(2) The effect on the Hb level of a small daily dose of iron introduced at different stages of gestation The stages chosen were the 16th, 20th, and 24th weeks The lower limit of the 16th week was selected because few mothers ordinarily make their first attendance at the clinic before that date, and the upper limit of the 24th week because beyond that date the blood changes associated with hydræmia have in many cases already taken place

(3) The value of the Hb level as an index of iron deficiency during pregnancy

Choice of Iron Preparation

For administrative reasons iron in tablet form was preferred, and, despite its disadvantages, no suitable alternative to tabellæ ferri sulphatis compositæ (*N.F*) was found When the investigation was planned, ferrous gluconate was unobtainable, and enteric coated tablets, although likely to overcome the nausea associated with tab ferr sulph co, were rejected because iron is absorbed mainly from the stomach and the upper part of the small intestine (Endicott et al 1949) Between 30% and 40% of pregnant women find it difficult or impossible to tolerate tab ferr sulph co (Benstead and Theobald 1952), but this intolerance may be partly psychological (Girdwood 1952) Accordingly we used, instead of the familiar green tablets usually issued at the antenatal clinics, white sugar coated tab ferr sulph co containing gr 3 of ferrous sulphate

Hæmatological Investigations

The values determined were Hb level, red cell count, colour index, packed-cell volume (P C V), mean corpuscular Hb concentration (M C H C), and mean corpuscular volume (M C V)

Specimens of blood were taken from patients every four weeks into bijou bottles containing Wintrobe's oxalate mixture Hb values were determined photo-electrically as oxyhæmoglobin in a single cell 'Biochem' absorptiometer (100% Hb = 14 5 g per 100 ml), P C V by Wintrobe's method, and red cell counts with a standard improved Neubauer hæmocytometer

Administrative considerations prevented the making of fresh films, but the use of oxalate films did not cause any difficulties All the films were stained with Leishman's stain and examined by one and the same observer

The colour-index was calculated in addition to the standard absolute values, to facilitate comparison with previous series

In some specimens the hæmatocrit revealed a degree of hæmolysis sufficient to invalidate blood count values These specimens were excluded from the investigation, and immediate repeat samples were obtained when

Reviews of Books

Sigmund Freud Life and Work

Vol II *Years of Maturity 1901–1919* ERNEST JONES, F R C P London Hogarth Press 1955 Pp 534 30s

WHEREAS a bad biographer adds a new terror to death, a good one assists towards immortality Much of Freud's published work and some one-sided recollections had created in people's minds a figure remote from the attractive, reserved, complex man of genius whom Dr Ernest Jones is now portraying for us with great skill and fullness The present volume describes the steadier yet troubled years in which Freud felt sure of his way, despite the painful schisms which gradually separated him from Jung, Adler, and Stekel These defections led to the formation of a committee of stalwarts, a secret council of trustworthy defenders of the citadel, to each of whom Freud gave an intaglio ring Dr Jones was the founder of this committee and in many other ways was at the centre of the psycho-analytic movement His contact with Freud was always close and unmarred by the doubts and rifts which were so distressing a feature of many of the personal relationships he describes with penetrating candour His portrait therefore has the authenticity derived from intimate acquaintance and access to much correspondence, as well as from the imaginative and intellectual sympathy of a devoted pupil and helper

The present volume is in three sections The first is a straightforward narrative of what happened to Freud and psycho analysis from 1901 until the end of the first world war The second is an organised survey of the voluminous writings in which Freud carried further his clinical and theoretical conceptions and applied them in diverse fields such as anthropology and literature The third section describes his mode of life and his character Inevitably it repeats much that has already appeared in the two volumes, but the full-length sketch of Freud as a man rounds out the total picture

Dr Jones has a great subject and ample materials, in his dignified, restrained account it is easy to see with what admiration and devotion he has approached his task

Land and People in Nigeria

K M BUCHANAN, B A, professor of geography, Victoria University College, Wellington, New Zealand, J C PUGH, M A, lecturer in geography, University College, Ibadan London University of London Press 1955 Pp 252 35s

THE subtitle of this book is the Human Geography of Nigeria and its Environmental Background, and the book has been written round 172 maps, mostly drawn by Professor Buchanan and Mr Pugh, which clearly illustrate the physical features of the country, the pattern of the population, agriculture, forests, mining and industry, transport, and the public and social services The information has been derived from published and unpublished material (largely from government sources) and from field observations made by the authors The direct medical interest lies in 19 pages on the prevalent diseases, and 2 pages on the medical services They could have been expanded to the advantage of the general reader

For instance, though it is stated that the epidemics of cerebrospinal fever are related to cold, dryness, wind, and dust, the mode of transmission—which make these factors important—is not described Similarly no account is given of the mode of spread of leprosy, relapsing fever, undulant fever, schistosomiasis, and onchocerciasis Guineaworm is related to water, but not in a manner which would be instructive to a water-engineer

The rest of the book is a detailed account of geography, in its wide sense, and because in most countries—and especially in Africa—the physical characters of the country, and the resulting economic and cultural background, strongly affect its diseases, this lucid account, rather than the short medical section, should prove invaluable to medical administrators and research-workers who adopt the biological and ecological approach to the study of disease advocated by Sir Macfarlane Burnet and others

One of the most important functions of a doctor is to make sure that changes in environment which may seem advantageous from the economic point of view are not carried out at the expense of health, another is to stimulate the proper people to change an environment when it is deleterious to health This book will help doctors to discharge both these responsibilities, and they will not find the information so attractively set out elsewhere

Modern Trends in Obstetrics and Gynæcology

2nd series Editor KENNETH BOWES, M D, F R C O G, obstetric physician, St Thomas's Hospital, London London Butterworth 1955 Pp 394 60s

THIS is in no sense a second edition Of the 26 chapters, nearly all are on subjects different from those covered in the first series It does not, therefore, attempt to be comprehensive, but in each chapter the busy specialist will find, in a well-condensed form, the important recent contributions to knowledge which should influence modern clinical practice The fact that ten of the chapters are by authors who are not themselves obstetricians or gynæcologists is a good indication not only of the scope of the book but also of the increasing importance to each specialty of work in related fields We hope that further series will be published from time to time because this volume, like its predecessor, correlates in a very helpful way the more academic and fundamental researches with the practical applications which arise from them

Problèmes de structures, d'ultrastructures, et de fonctions cellulaires

Published under the direction of J ANDRÉ THOMAS, professeur de biologie cellulaire a la Sorbonne Paris Masson 1955 Pp 358 Fr 3300

THE articles in this volume are amplifications of ten lectures given at the Sorbonne during the spring of 1954 They deal with the applications of the physical and biological sciences to the problems of cellular biology They are perhaps too specialised for the general reader but they will be of value to those who can read them critically

J Barraud briefly summarises the information to be obtained from classical and X ray crystallography and goes on to consider crystal growth, the biosynthesis of proteins, and the theories concerning the rôle of desoxyribonucleic acid in this latter process R Wurmser describes the elucidation of the active groups on enzyme molecules and the nature of the forces which attract the substrate molecules to it He also discusses the application of thermodynamics to this study and the process of electron transfer in the cytochrome complex L R Rey, in his paper on the structure of the desoxyribonucleic acid molecule, gives prominence to the recent work of the X-ray crystallographers but does not neglect the earlier work on the anomalous viscosity, birefringence, diffusion, electrophoretic mobility, sedimentation, and other physical properties

D G Dervichian reviews some of the theoretical structures of cell membranes and describes the kinetics of active and passive penetration Ch Devillers discusses cellular adhesion and morphogenesis He describes investigations on the nature of the adhesive substances, the changes brought about by simple molecules and ions, and their relation to morphogenesis René Couteaux, in his article on inter tissue junctions, describes the structure and function of nerve sheaths and various motor and sensory nerve end organs

A Fessard's description of the ultrastructures and functions of the neurone is mainly concerned with the evidence obtained with the electron microscope Tracings obtained with intracellular electrodes are rather elegantly displayed alongside photomicrographs showing the electrodes in position The paper of Ch Oberling and W Bernhard is devoted exclusively to the electron micrography of cancer cells C Thibault describes recent work done on the survival of spermatozoa and the conservation of their fertility He deals with the protective effect of egg yolk, milk, and other diluters, and the rôles of oxygen, temperature, and antibacterial drugs in conserving fertility Finally, R Coujard describes the pioneer work of Reilly and his own interesting experiments on "sympathetic" lesions

showing a significant fall in the M C H C or a fall in this index below 32% there was also a fall in the Hb level.

Discussion

The administration of iron during pregnancy presents certain difficulties. It has been estimated that 30–40% of expectant mothers will not take ferrous sulphate tablets routinely prescribed (Benstead and Theobald 1952). It has also been stated that iron administered during pregnancy does not maintain the Hb level (Hahn et al. 1951).

In this series the controls showed the changes associated with the hydræmia of pregnancy: the M C H C fell from a normal 32.6% at 16 weeks to 30.2% at full term—a level indicating iron deficiency not amounting to anæmia (Discombe 1954).

In the three groups treated with iron, however, the hæmatological values were maintained within normal limits throughout pregnancy in 69 out of 89 cases (77.6%) by the administration of a small daily dose (gr. 9) of ferrous sulphate.

Because of the relatively small number of expectant mothers included in the investigation the findings cannot be regarded as conclusive, but they do suggest that normal hæmopoiesis is only possible in the presence of an adequate intake of iron. These findings are therefore in keeping with those of Young et al. (1946), Cartwright and Wintrobe (1949), Scott and Govan (1949), Ventura and Klopper (1951), Benstead and Theobald (1952), Davis and Jennison (1954), and Fisher and Biggs (1955). The findings also indicate that the Hb level can be maintained by smaller doses of ferrous sulphate than those generally used. This is in keeping with the findings of O'Sullivan et al. (1955).

Only 8 women (5.4%) were excluded from the investigation because of intolerance to iron, and only 1 of the remainder who received iron complained of nausea of sufficient severity to interfere with her taking the tablets.

TABLE IV—MEAN HÆMATOLOGICAL FINDINGS IN 20TH-WEEK AND 24TH WEEK GROUPS

Period of gestation (wk.)	20th week group (33 cases)				24th week group (35 cases)			
	Hb (%)	P C V (%)	M C H C (%)	M C V (c μ)	Hb (%)	P C V (%)	M C H C (%)	M C V (c μ)
20	83.6	36.8	32.8	88.3	—	—	—	—
24	80.2	36.1	32.6	89.5	83.4	37.7	32.5	88.2
28	80.0	36.0	32.3	89.0	82.8	36.4	32.7	88.3
32	80.6	35.0	33.0	89.4	81.6	36.6	32.6	88.0
36	81.2	36.0	32.3	89.3	84.4	37.2	32.4	87.3
40	84.0	38.1	32.8	91.5	85.5	37.2	32.6	89.1

Although the mean Hb levels were maintained in the three groups taking iron, the Hb levels of 20 of 89 mothers in these groups were not maintained.

Since none of these patients had an anæmia not associated with iron deficiency, or suffered any blood-loss, the fall in Hb level can only be attributed to the following causes:

(1) The mothers did not take the tablets (this was not established).

(2) The iron was not absorbed.

Non-absorption of administered iron has been reported by Scott and Govan (1949), Fisher and Biggs (1955) and O'Sullivan et al. (1955).

The Hb level is related both to the P C V and the M C H C, and a fall in the Hb level may be associated with a fall in either or both of these indices. A fall in the P C V is associated with hydræmia, and a fall in the M C H C with a decrease in the iron content of the red cells. The Hb level during pregnancy therefore cannot by itself be taken as an accurate index of iron deficiency unless the P C V remains stationary. This does not, however, lessen the usefulness of the Hb level in antenatal clinics.

Full hæmatological examination cannot be applied to even one sample of blood from every expectant mother attending an antenatal clinic, because this would place an impossible burden on laboratory services, and it is unnecessary.

In the absence of evidence of anæmia the following routine is suggested:

(1) The Hb level should be estimated at the first visit of every expectant mother to an antenatal clinic irrespective of her period of gestation.

(2) Every expectant mother should receive iron as a routine.

(3) The Hb level should be estimated again between the 32nd and the 36th weeks to determine whether it is being maintained.

If the Hb level is not maintained, a full hæmatological examination should be undertaken to determine the reason for the fall.

The Hb level used in this way can be a simple and reliable guide for routine purposes. Table I shows that the later an expectant mother attends for her first antenatal examination the more likely is she to have a low Hb level, and that in most cases this indicates a deficient intake of iron. Every expectant mother should therefore be encouraged to attend for antenatal care as early in pregnancy as possible.

Summary and Conclusions

A tendency to iron deficiency was revealed in expectant mothers by a progressive fall in Hb level, red-cell count, colour-index, P C V and M C H C. In a comparable group this tendency was prevented, and the hæmatological values maintained within normal limits, by the administration of a small daily dose of iron in the form of ferrous sulphate (gr. 9 corresponding to 315 mg. of elemental iron). Only 8 women (5.4%) were excluded from the investigation because of intolerance to iron, and failure to respond was observed in 20 of 89 cases (22.4%). Possible reasons for this failure are discussed.

The use of ferrous-sulphate tablets as a routine measure was effective in maintaining the Hb level and other hæmatological indices throughout pregnancy in 77.6% of 89 cases.

For the purposes of antenatal care routine estimation of the Hb level is a useful guide to the behaviour of the more accurate hæmatological indices and of determining the response to oral iron.

The Hb level should be estimated at the first visit and again at 32–36 weeks. Further hæmatological of local anæsthesia The greater part of the book is concerned with the indications for operation and the management of its complications The common clinical conditions are well described, but the illustrations are indifferent

Recent Advances in Neurology and Psychiatry (6th ed London J & A Churchill 1955 Pp 311 30*s*)—In the ten years that have elapsed since the previous edition neurology has made many advances Under the editorship of Sir Russell Brain and Dr E B Strauss this book has been entirely rewritten, and three extensive chapters included on electro encephalography by Denis Hill, neuroradiology by David Sutton, and intracranial tumours by Douglas Northfield The references at the end of each section are numerous and recent, and the authors have shown good judgment in selecting the papers that deserve special notice The exposition is concise and to the point As the preface rightly states, the common ground between neurology and psychiatry increases in importance This is well illustrated in the chapter on consciousness and unconsciousness, and that dealing with the parietal lobe Unfortunately another relevant chapter, on the mental aspects of the frontal lobe, falls below the standard maintained in the rest of the book

Biographical Memoirs of Fellows of the Royal Society (Vol 1 London The Royal Society 1955 Pp 263)—The Royal Society has started a new series in continuation of the *Obituary Notices of Fellows of the Royal Society* which covered the years 1932–54 in nine volumes This first group contains 19 biographies of varying length, including those of Sir Stafford Cripps and Albert Einstein, all written by distinguished colleagues Each is accompanied by a photograph and a bibliography of published works Some of the portraits show the remarkable artistry of Karsh of Ottawa The biographies are of so high a class that they could be bettered only by a full scale book about each fellow Three are of particular interest to the medical reader Frederic Wood Jones and Arthur Keith by Sir Wilfrid Le Gros Clark and Edward Mellanby by Sir Henry Dale They reawaken admiration for the accomplishments of each of these men in such wide fields

New Inventions

A BED CRANE

The crane illustrated here was made for a patient who had severe paralytic poliomyelitis in 1949 and was left with flaccid paralysis of both legs and weakness of the muscles of her trunk and right upper arm For six years she could not lift herself out of bed into her wheel-chair or on to a bedpan without help

Mr James Genet, senior orthopædic technician at Wellington Hospital, designed the crane to give the patient much greater independence, particularly when getting to and from her bed and wheel-chair He has successfully achieved this and considerably improved her morale

The apparatus consists of a frame clamped on to the end of the bed and incorporates an ordinary motor-car hydraulic jack, which the patient works with the handle, jacking herself up off the bed or the wheel-chair She then very easily moves herself over to the wheel-chair or the bed and lowers herself by turning the handle which decompresses the jack

The crane can also be used by nurses to lift patients off beds and on to wheel-chairs and, if the sanitary type of chair is used, for taking them to the lavatory or to a shower where they can be washed, thus obviating the difficulties of bathing, particularly in the case of heavy elderly patients

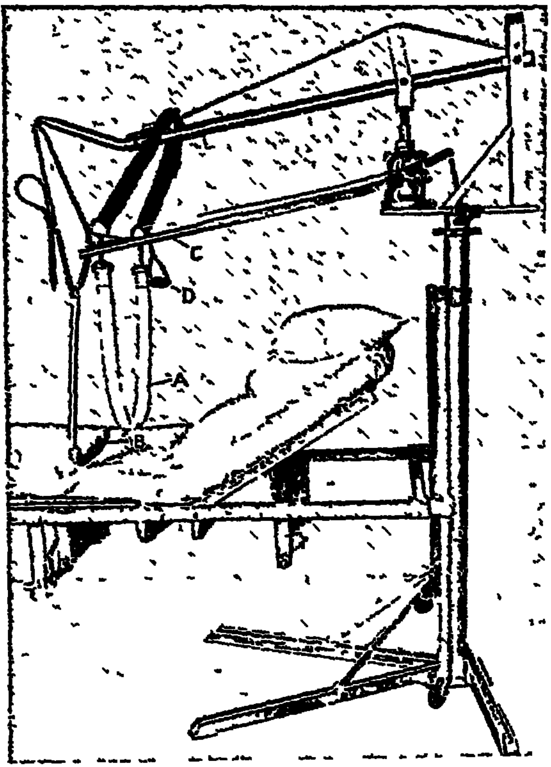

Fig 1—The crane in position A, sling to pass under arms and around patient's back, B, sponge-rubber and leather-covered hook to pass under patient's knees, C, operating handle of jack D, hand grip which is control for raising or lowering the patient and is working handle for C in certain positions To lift patient, handle is pushed fully in towards jack by giving hand grip a quarter-turn and pumping To lower, hand grip is turned until handle is pulled about $^1/_2$ inch out of jack, handle is then pressed down as far as possible Slinging is so arranged that front strap runs over roller on spreader, this action transfers patient from partly prone position on bed to sitting position on wheel-chair A stop prevents patient from swinging too far

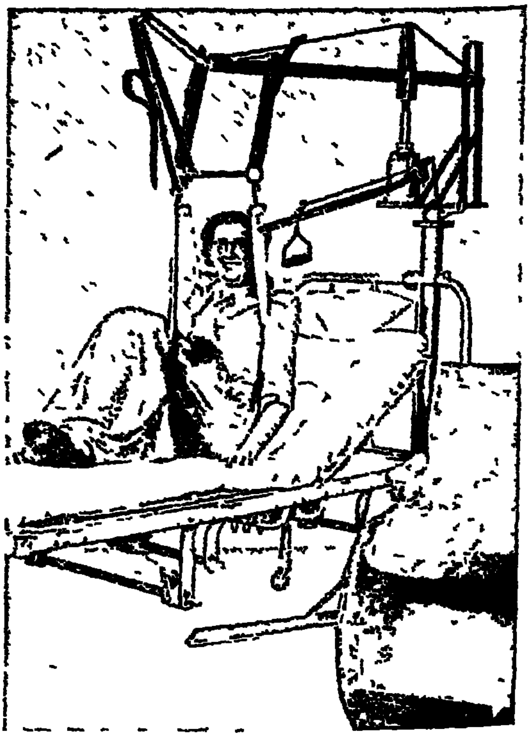

Fig 2—Patient in sling

This apparatus cost about £23 to make The price compares very favourably with that of other apparatus on the market The apparatus can be made mobile by being fitted with castors, future models will be so fitted

Mr Genet feels that it is wrong to patent apparatus of this kind and it is therefore available for any hospital to copy

I A M PRIOR
M D N Z, M R C P, M.R.A C P

issue indicating that the B C G had taken successfully Of the remaining 3 persons who failed to react to either "depot" or aqueous tuberculin, 2 had failed to convert after previous B C G vaccination, and 1 had converted transiently after vole bacillus vaccination

Patients with Sarcoidosis

The responses to 100 T U of aqueous tuberculin and 5 T U of "depot tuberculin" were compared in 23 proven cases of sarcoidosis of various degrees of activity The results were

Positive reactions to both the aqueous and "depot" tests	4
Negative reactions to both the aqueous and "depot" tests	6
Positive reactions to the "depot" test only	13
Positive reaction to the aqueous test only	0

	Negative	*Positive*
Aqueous tuberculin	19	4
"Depot tuberculin"	6	17

The "depot tuberculin" produced a brisk erythematous reaction about 35 mm in diameter with central induration of 5–10 mm within two days, except in 2 persons in whom an erythematous reaction appeared after seven days in one and nine days in the other

Discussion

We know little of the fate of tuberculin in the tissues except that it starts to become fixed early, and that this is completed within one to two hours with a moderate skin-test dose (Pepys 1955a) The proportion of injected tuberculin retained locally by this "fixation" is unknown, but factors which influence its local persistence can modify reactions considerably Increased lymphatic absorption of the tuberculin decreases reactions, whereas increased local retention increases reactions (Seeberg 1947, 1951a, Pepys 1953, 1955a) The long persistence of the tuberculin—e g, with a "depot tuberculin"—favours a higher concentration for a longer period and leads to prolonged reactions in Mantoux-positive people Such an enhancement could be expected to reveal lower degrees of sensitivity not elicited by aqueous tuberculin

The interval of about ten days between the B C G vaccination and the appearance of reactions at previously negative "depot tuberculin" tests corresponds to the time required for the development of hypersensitivity due to the infection These reactions correspond to Wassen's (Wassen and Swedin 1941) findings in rabbits He injected "depot tuberculin" into their skins and then infected them with tubercle bacilli The "depot" tests reacted sixteen days after the infection, at which time aqueous Mantoux tests were also positive These observations resemble the "revivescence" reaction in man, in whom previously negative tuberculin skin tests become positive on the appearance of active tuberculous infection, even months later, thus indicating the persistence of some of the tuberculin locally

The "depot" tests were used as a deliberate "revivescence" test in the B C G vaccinated subjects In the 2 patients who failed to react to aqueous tuberculin but gave positive reactions to the "depot tuberculin," the presence of tuberculous tissue at the B C G vaccination sites was evidence of a successful take In these patients the "depot" material may have revealed a degree of sensitivity too low to be elicited by the aqueous tuberculin In the ordinary way these patients would have been regarded as candidates for repeated B C G vaccination on the assumption that a failure to react to 100 T U of aqueous tuberculin meant that they had not converted There are reports of Mantoux-negative B C G -vaccinated people in whom enhanced reactions to revaccination with B C G showed that they were hypersensitive to the product of these organisms (Saye 1948) The positive reactions to the "depot" tests in these 2 patients were evidence of conversion to tuberculin hypersensitivity

The positive "depot" tests in patients with sarcoidosis may be due to a similar demonstration of a low degree of sensitivity which escapes aqueous tuberculin testing Seeberg (1951a) obtained positive "depot" reactions in 6 of 8 Mantoux-negative patients with sarcoidosis He claims that histological examination of the sites of these negative Mantoux tests in patients with sarcoidosis shows evidence of a tuberculin-type reaction, and he regards this as evidence of "latent" tuberculin sensitivity (Schaumann and Seeberg 1948) He suggests that the reaction to the "depot tuberculin" in patients with sarcoidosis is due to the prolonged retention of the tuberculin, which enables sufficient antibody carrying cells to arrive and to react with the tuberculin There is general agreement that the proportion of patients with sarcoidosis who fail to react to 100 T U of aqueous tuberculin is higher than in the general population That these patients with sarcoidosis may nevertheless be basically tuberculin-sensitive is shown (1) by the reactions elicited with "depot tuberculin" by Seeberg (1951b) in 6 of 8 patients and by us in 13 of 19 patients who failed to react to aqueous tuberculin, and (2) by the report of Pyke and Scadding (1952) that Mantoux-negative patients with sarcoidosis could give positive tuberculin reactions when tested while under cortisone treatment

Recent reports indicate that the sources of antibody responsible for the tuberculin type of hypersensitive response are cells of reticulo endothelial origin, and that circulating lymphoid cells appear to be responsible for the initiation of the reaction (Pepys 1955b) The results of "depot tuberculin" tests in patients with sarcoidosis suggest that these cells are a poor source of reacting antibody in this disorder This may explain the decreased sensitivity of such patients to a variety of delayed-type hypersensitive antigens (Sones and Israel 1954) The deficiency of delayed-type hypersensitive antibody is in contrast to the ready production of circulating antibodies in patients with sarcoidosis (Sands et al 1955) Circulating antibodies are concerned in hypersensitive reactions of the immediate type, and there are many reports of undiminished reactivity to immediate-type tests in patients with sarcoidosis

The remaining 6 patients with sarcoidosis who gave negative reactions to both aqueous and "depot" tests may be considered to be either insensitive to tuberculin or less sensitive than those patients who reacted to the "depot tuberculin" Some of the completely negative patients were among the more active cases, as judged by the more recent onset, florid skin changes, raised erythrocyte sedimentation rate, and positive Kveim test As regards the response to inflammation, there does not appear to be any obvious impairment in patients with sarcoidosis, since they reacted vigorously to the "depot tuberculin"

Summary

The reactions to intradermal injections of tuberculin in aqueous solution and in an oily emulsion ("depot tuberculin") were compared

In 5 Mantoux positive subjects, the oily tuberculin excited reactions which persisted for three months No reactions were produced in Mantoux-negative subjects.

In 6 of 9 Mantoux negative subjects vaccinated with B C G, positive reactions appeared within ten days of vaccination, at the sites of previously negative "depot tuberculin" tests made four weeks before the B C G. vaccination

4 patients with sarcoidosis gave positive reactions to both the aqueous and "depot" tuberculin Positive reactions were elicited by the "depot tuberculin" in 13 of the remaining 19 patients with sarcoidosis who did not react to aqueous tuberculin

The long local persistence of the tuberculin in the oily emulsion probably made it possible to demonstrate degrees of sensitivity too low to be revealed by aqueous tuberculin tests

FIFTIETH ANNIVERSARY Lederle

LEDERLE LABORATORIES DIVISION

Cyanamid PRODUCTS LTD LONDON, W C 2

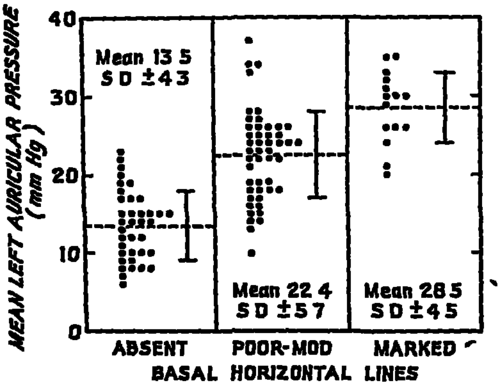

Fig 2—Relation of lines to mean left auricular pressure

patients into the three radiographic groups is shown fig 2, which also indicates the range of pressures in ch group In the "lines absent" group, the individual ressures are scattered about a mean value of 13 5 mm g, and in the "poor to moderate" and "marked" oups the means are 22 4 mm Hg and 28 5 mm Hg spectively These means show clearly the higher ressures found in the groups with lines Thus, the resence of lines on the chest radiograph of a patient th mitral disease seems to be direct evidence of a nsiderably raised left auricular pressure at the time e film was taken

elation between Horizontal Lines and Mean Pulmonary rterial Pressure in 64 Patients with Mitral Disease

No lines were found below a mean pressure of 4 mm Hg, but they were consistently present above 1 mm Hg The classification into groups and the istribution of the pressures are shown in fig 3 In each group the range of pressures is much greater than in fig 2, as indicated by the standard deviations shown for comparison in figs 2 and 3

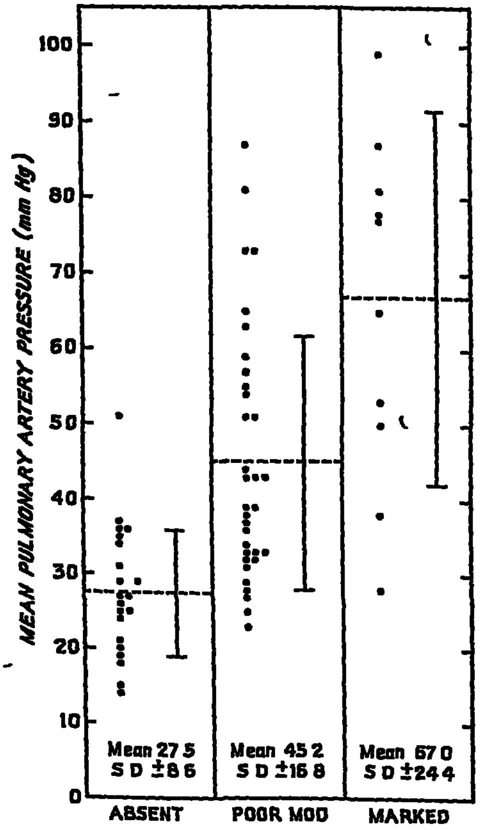

Fig 3—Relation of lines to mean pulmonary arterial pressure.

Statistical comparison of the three radiographic groups in the association of left auricular pressures with lines (fig 2), shows the difference between the means of any two groups to be highly significant When pulmonary arterial pressures are considered (fig 3), although the difference between the means of the "absent" and "poor to moderate" groups is highly significant, that between "poor to moderate" and "marked" is only moderately significant The statistical data are summarised in table I

Relation between Lines and Mean Pulmonary Arterial Pressure in 16 Patients with Pulmonary Hypertension from Causes other than Mitral Disease 4

Although the mean pressure for the whole group was 73 mm Hg, only 2 showed doubtful lines, and no lines were seen in the remaining 14 patients For 5 of the patients, measurements of left auricular pressure were available, 4 made during bronchoscopy, and 1 during cardiac catheterisation through an auricular septal defect All these left auricular pressures were normal Table II summarises the data from these 16 patients These findings suggest that whereas patients with mitral disease and severe pulmonary hypertension almost invariably have lines, pulmonary hypertension alone is not the cause

TABLE I—CLASSIFICATION OF RADIOGRAPHS IN PATIENTS WITH MITRAL DISEASE

—	Group 1 (lines absent)	Group 2 (lines poor to mod)	Group 3 (lines marked)
Mean lt auricular pressure (mm Hg)	13 50 ±4 312*	22 44 ±5 709*	28 53 ±4 514*

, 1 and 3 $t = 10.91$ $n = 50$, $p < 0.001$
† Comparison 1 and 2 $t = 4.383$ $n = 52$, $p < 0.001$
, 2 and 3 $t = 3.095$ $n = 41$, $p < 0.01$
,, 1 and 3 $t = 6.404$, $n = 29$, $p < 0.001$

Discussion

From the results presented above, three important facts emerge

1 Basal horizontal lines on the chest radiographs of patients with mitral valvular disease are accompanied by a raised left auricular pressure

2 Lines invariably appear when the mean left auricular pressure exceeds 24 mm Hg

3 Elevation of the pulmonary arterial pressure alone appears to play little part in the production of lines

The first two of these facts suggest that the factor responsible for radiographic evidence of lines is a rise in pulmonary capillary venous pressure to a level exceeding the colloid osmotic pressure of the plasma proteins This is indirect evidence for the now widely accepted view that the anatomical basis of the lines is an increase in the bulk of the interalveolar septa Distension of these with tissue-fluid leads to the production of distinct and characteristic shadows on the chest radiograph

From fig 2 it seems that the scatter of the individual pressures about the means is larger than might have been expected Some overlap of the pressures in the three groups is apparent, and the following reasons may account for this

1 The time-interval between taking the chest radiograph and recording the pressures is important, this is illustrated by the following case-record

A woman, aged 41, with mitral stenosis was orthopnœic when first seen in May, 1955, and her chest radiograph then may develop after a surgical portacaval anastomosis if hepatic function is impaired , but shunting of portal blood into the systemic circulation in the presence of a healthy liver does not produce the syndrome Neurological and mental changes may also appear as the result of the severe liver damage which occasionally follows virus hepatitis Clearly hepatic function must be depressed before this condition can arise, and its onset is precipitated by the development of communications between the portal and systemic veins Moreover, the neurological disorders can be induced by raising the intake of nitrogenous substances, such as dietary protein, ammonium salts, and urea Methionine, which has in the past been used in the treatment of liver disease, may have a similar effect,[4–7] and **SHERLOCK** and her associates have investigated the mechanism of this action [8] Methionine given by mouth produced neurological deterioration in 7 out of 9 patients who had previously had episodes of impending hepatic coma It was without effect in other patients with hepatic cirrhosis who had never had neurological complications The rise in the blood-methionine level was the same in the two groups Intravenous methionine had no effect in 3 patients who had previously relapsed after oral administration and in 1 it produced only a delayed exacerbation No significant change in blood ammonium, pH, or bilirubin level accompanied the neurological deterioration produced by methionine When chlortetracycline (aureomycin) was given at the same time as methionine, no toxic disturbances developed in patients who had previously reacted, despite the fact that higher blood-methionine levels were reached when the antibiotic and amino-acid were given together These observations suggested that the toxicity was not due directly to methionine but to some substance derived from methionine by the action of intestinal bacteria sensitive to chlortetracycline Bacteriological studies showed that the fæcal flora of patients with liver disease and neurological disturbances was no different from that of healthy people and of patients with uncomplicated cirrhosis Methionine by itself did not alter the bacterial composition of the fæces Chlortetracycline produced similar changes in all three groups—namely, a rise in proteus with elimination of bacteroides and an inconstant fall in *Escherichia coli* The streptococcal types changed and lactobacilli increased

The breakdown product of methionine responsible for the neurological changes has not so far been identified Clearly, however, methionine is potentially toxic if given by mouth to patients with hepatic cirrhosis In the past methionine has been recommended on rather slender grounds as a treatment of liver disease, but there is no definite evidence that it does any good, and its use should certainly be abandoned Chlortetracycline has already been given with apparent success in the treatment of hepatic coma [9] The neurological disturbances that may appear spontaneously in cirrhosis of the liver vary greatly in severity, and the effect of treatment is difficult to assess accurately , but **SHERLOCK** et al 's clinical impression is that chlortetracycline therapy is of benefit in spontaneous hepatic coma Other measures must of course be used—in particular, curtailment of the intake of protein and other nitrogenous substances during the acute phase of the disturbance

Hypoglycæmia in Diabetics

WHENEVER hypoglycæmia in a diabetic cannot be attributed to one of its usual causes—failure to eat, over-exertion, or too much insulin—other possibilities must be considered The blood-glucose comes from the alimentary tract or from the liver by glycogenolysis or gluconeogenesis Poor absorption may cause hypoglycæmia in myxœdema [1] and sprue,[2] and glycogenolysis is deficient in some types of hepatic failure, even without other obvious signs of liver disease [3] The liver may fail because it contains too little glycogen or because it is unable to mobilise stored glycogen as in von Gierke's disease, and possibly in the type of brittle diabetes with hepatomegaly recently described by **EVANS** and his colleagues [4] Gluconeogenesis is largely dependent on the adequate function of the adrenal cortex and thus indirectly of the anterior pituitary The association of diabetes with Addison's disease and Simmonds's disease is admittedly uncommon [5 6] , but early recognition of adrenal insufficiency in a diabetic is particularly important, for these patients become extremely sensitive to insulin, in the same way as the Long cat [7] or the Houssay dog,[8] and hypoglycæmia may well be fatal before the true state of affairs is appreciated [9] Such a diabetic, previously needing much insulin, may be able to do without any at all, although an intravenous glucose tolerance test will still show a diabetic curve After infarction of the anterior pituitary for example, there is characteristically a severe headache followed in a day or two by hypoglycæmic reactions to the usual doses of insulin [10] If the patient survives, and insulin treatment is either drastically curtailed or stopped, signs of hypofunction of the gonads and thyroid gradually appear, but they respond well to replacement treatment Diabetic intercapillary glomerulosclerosis (Kimmelstiel-Wilson syndrome) may sometimes be associated with decreasing insulin needs,[11] but no satisfactory explanation has been suggested **RUNYAN** et al [12] concluded that the renal lesions were not related to any change in insulin needs

The importance of hypoglycæmic episodes in prognosis lies in the susceptibility of the brain to what may be irreversible damage [13] The risk is greatest after long-continued severe hypoglycæmia and in

FŒTAL MORTALITY IN PREGNANT DIABETICS

STRICT CONTROL OF DIABETES WITH CONSERVATIVE OBSTETRIC MANAGEMENT

Jørgen Pedersen
M.D. Copenhagen
CONSULTANT PHYSICIAN IN DIABETES

E. Brandstrup
M.D. Copenhagen
PROFESSOR OF MIDWIFERY

ROYAL MATERNITY DEPARTMENT B, RIGSHOSPITALET
COPENHAGEN, DENMARK

Pregnancy in diabetics has not been studied long, and not until the 1940s was it generally known that the fœtal mortality was still very high (about 40%) and not much different from the mortality in the pre-insulin era, in contrast to the prognosis of the mothers, which became good after the advent of insulin.

It seemed to us that, before introducing any additional therapy, we should determine the basic fœtal mortality after intensive classical treatment. Accordingly in January, 1946, we started in this department a clinical trial of strict control of the diabetes and conservative obstetrical management by a few doctors.

This trial has now lasted nearly ten years, so we outline our treatment and report the fœtal mortality observed during that time. The material comprises 265 cases from January 1946 to Sept. 30, 1955. In addition we use for comparison our old Rigshospital material of 1926–45, comprising 157 cases—a grand total of 422 cases.

Control and Treatment

The mother is examined as an outpatient every three weeks during the first four months of pregnancy and then weekly. About eight weeks before the expected term she is admitted to hospital and remains there until delivery, which is induced about three weeks before term.

The main feature of our new programme is the control and treatment of the diabetic in hospital during the last months of pregnancy. Our aim is to obtain the best possible chemical control of diabetes by giving a measured diet and plenty of insulin. The diet contains about 1900 calories, 80–90 g. of protein, 175–200 g. of carbohydrate, and about 80 g. of fat, and in addition a supplement of vitamins, calcium, and iron is given. The blood-sugar level is controlled by altering the insulin dosage and by distributing the diet over five or six meals, according to individual requirements. We nearly always use protamine-insulin retard (N.P.H. insulin) combined with ordinary insulin twice a day, the average daily dose being 70 I.U. Capillary blood-sugar determinations, of which three are postprandial, are made four times daily by the Hagedorn-Jensen method (total reduction), and we try to keep the blood-sugar at the physiological level. The extent to which this aim is attained is exemplified by the fact that in the first 18 long-term treated cases (see below) the level of the blood-sugar (average of the four daily determinations during the last continuous stay in hospital, which averaged 52 days for the 18 patients) ranged from 108 to 167 mg. per 100 ml., the over-all average being 133 mg. per 100 ml. In the later years we have calculated the average level for one day now and then and found averages of 133, 135, and 130 mg. per 100 ml.

To combat toxæmia, hydramnios, and œdema, table salt is restricted. Phenobarbitone has been administered in some cases, and abdominal amniotomy tried in a few, but no hormones, mercurial preparations, ammonium chloride, rutin, or similar substances are used.

Pregnancy is usually terminated at the beginning the 38th week, on average 20 days before the calculate term. Nearly all deliveries are induced with dru and/or by rupture of the membranes. Up to now onl 29 cæsarean sections (11%) have been done on obstetric indications, whereas low forceps deliveries are commo In about 20% of the cases labour started spontaneousl

As a routine the newborn babies are placed incubators and given oxygen, warmth, and humidit for the first twenty-four hours. During this period th babies are fasted (Pedersen 1952, Pedersen et al. 1954 A pædiatrician is called when needed.

The treatment of long-term treated patients (se below) during the ambulatory period and the dail treatment of all inpatients are given by one physicia (J. P.). The delivery too is managed by only a fe doctors under the supervision of one of us (E. B.).

Long-term and Short-term Treatment

Knowledge of the control and treatment of diabete in Denmark is essential for an understanding of wha follows. The control is decentralised, and apart fro two private hospitals for diabetics (Steno Memori Hospital and Hvidöre Hospital) we have no diabet clinics or units; the treatment is given by gener practitioners and to some extent by medical outpatien departments, specialised physicians, and the two abov mentioned clinics. The antenatal care too is decentra ised, and we have only a few obstetrical outpatien departments in Denmark.

Our department receives emergency cases and a kinds of obstetrical complications without selection, an from 1946, all pregnant diabetics wanting or needin admission to the Rigshospital. We have pleaded wit diabetics to get in touch with this department not late than about the 30th week of pregnancy.

Thus the diabetics attend our department at ver different stages of pregnancy, a few from the earlie months and others not until they are in labour. But mos of them are seen toward the end of pregnancy. Thus w have not been able to follow our recommended schedul for all the patients, and they have not had the sam amount of control and treatment. We have to divid the material according to the amount of treatmen received, but this must be done by dividing according t the stage of pregnancy at which the patient first applies t the clinic, because this determines how long the patien might be treated. Those who are seen at least 53 day before the calculated term are classified as long-ter treated, and those who are not seen until later as short term treated. (These phrases should not be confused— as has been done—with long-term and short-ter diabetes.) The patient is always designated short-ter if she is in pre-coma or in labour or has already bee delivered when first seen. Likewise short-term applie if delivery takes place, or the baby dies, within 8 day after the patient's first application for admission.

This classification is objective and unbiased and i made 9 days after the patient's first application. Th reason for choosing 53 days before term is historical an is explained by Pedersen (1954a). The criterion fo long-term treatment makes the results in this grou seem worse than they are because the deaths of babie whose mothers applied to the hospital in due time ar allotted to the long-term group after only 8 days treatment, whether the mothers have been outpatient or inpatients during this short period.

The most important difference between the long term and short-term groups is the length of treatmen in department B (table I): 78% of long-term but only 10% of short-term patients stayed continuously i hospital for 30 days or longer immediately before delivery In other words, the long-term group was admitted to hospital on an average on the 65th day before the there is a risk that the claims for what can be accomplished, mentally and physically, for the spastic have been too optimistic There has been a tendency to regard the solution too much in terms of finance, of bricks and mortar rather than plodding and dispassionate scientific study Money is, of course, of immense importance in this unusually difficult and costly programme, and it may well be that the British Council for the Care of Spastics, with its more professional membership, has failed to appreciate the sense of urgency, enthusiasm, and passionate vigour of the National Spastics Society

At any rate, surely the time has come for an effective working compromise—for the union of the cautious, objective, professional approach of the council with the lively strength of the "parents" movement To have a permanent division means duplication and overlapping —for example, in having separate medical advisory committees, and this must lead to rivalry and a competitive spirit at the expense of the real welfare of spastics This view was taken by the Archbishop of Canterbury, and it has been supported by the director-general of the National Society, Lieut-Commander Ian Henderson, apparently to his own discomfiture The main principle at issue is the question of where ultimate control should lie The articles of association of the National Spastics Society hold the provision that not less than two thirds of the members of the executive committee must be spastics or parents of spastics The British Council has always had parents on its committee, but it is mainly representative of medical, educational, and other professional bodies which are deeply interested in the subject National interests should take precedence over local demands, and there is a very real need for balance and judgment

FORM OF CONSENT

IN law, a patient must not be examined or treated unless consent has been given The question is seldom raised in the law courts, for consent is usually taken for granted, but the principle is obviously a sound one, and its neglect can be dangerous Except in an emergency, when prompt action is essential, consent is always obtained before operation or the giving of an anæsthetic, but specific permission is less regularly sought before investigations which the doctor is apt to regard as routine An intradermal tuberculin test on a child is an example of a minor procedure which it is unwise to undertake without the agreement of parents, indeed tests of this nature, and prophylactic injections, are seldom done by local authority doctors without it Clearly, the need for permission is greater where the patient is a child, but adults, too, are entitled to a careful explanation of the investigation or treatment proposed Consent by word of mouth, in the presence of a witness, is acceptable in law, but a written declaration is, of course, legally safer On the other hand, an "omnibus" form of consent, couched in general terms, may be open to strong objection, for the purpose of getting consent is to be sure of the patient's approval of something he has genuinely understood

This subject was discussed recently by a hospital management committee[1] whose medical advisory committee recommended the introduction of a special consent form The form had particular reference to investigations and tests which adult and child patients might require, and we understand that the immediate reason for the request was the (highly commendable) proposal to Mantoux-test all children on admission The management committee, however, were reluctant to grant powers of examination and investigation on so wide a scale, and decided to defer decision until at least they had seen suggested forms of consent drawn up by the medical committee after consultation with an appropriate medicolegal organisation The publicity given to their discussion of this important issue may stimulate other management committees to review their own arrangements, in collaboration with their medical committees The safeguarding of doctors against unreasonable litigation can be important, but even more important is the safeguarding of patients against investigation or treatment they do not desire The good relationship of patient and doctor, in hospital or elsewhere, depends on confidence, which should be founded as firmly as possible

EXIT PLOMBAGE ?

BEFORE chemotherapy tilted the balance of opinion in favour of resection, thoracoplasty was regarded as the best major operation for the treatment of pulmonary tuberculosis The results indeed were good, and the gross demolition of the upper thorax that was necessary to secure them was viewed tolerantly by clinicians though less so by patients Chemotherapy has radically changed all this, and past standards have slipped into the discard so rapidly that many stoutly held principles have had to be revised and established methods subjected to searching review

Apical plombage was *not* an established method before the introduction of chemotherapy, but it had been tried with some success in America by Wilson[1] The initial idea was that the introduction of an inert plastic substance into the extrapleural space would overcome the disadvantages inherent in extrapleural pneumothorax, and at the same time leave the patient with an intact chest wall Complications, however, as reported by Trent et al[2] and Walkup and Murphy,[3] were far too many and serious, particularly as regards pressure phenomena, to warrant the continued use of the operation, and the plomb was then placed extraperiosteally where it could do less damage to the lung and great vessels, the periosteum, after separation from the ribs, formed with the attached intercostal muscles a protective barrier between the plomb and these vital structures, and results became more encouraging Soon it appeared that, except when the apex of the lung was grossly adherent, apical plombage would constitute a serious rival to thoracoplasty and even bid fair to replace it as the main surgical measure Early results were good,[4–6] particularly as new and more suitable plastic materials were forthcoming, surgeons and patients alike were pleased with the one stage no deformity operation which had so few postoperative complications, and chemotherapy at first seemed to confirm these impressions by rendering the disease less active at the time of operation, thus further diminishing the risk of complications But the well known hazards of the permanent retention of a foreign body in the tissues were not to be so easily overcome Infection sometimes revealed itself early, when it was usually staphylococcal, more often it appeared late, and it was then commonly due to the tubercle bacillus[7] Ruefully, the infected plombs were removed and thoracoplasty performed to close the space The main cause for concern is that infections continue to become manifest some years after *operation and* it is this factor which completely undermines confidence Meantime, resection in the increasingly favourable conditions produced by more thorough preoperative chemotherapy has rapidly

TABLE IV—FŒTAL MORTALITY * FROM 1946 TO SEPT 30, 1955, CLASSIFIED BY BIRTH-WEIGHT AND ACCORDING TO WHITE (1949) IN 265 BABIES

Classification	Treatment			
	Long term		Short term	
	No of babies	Fœtal loss	No of babies	Fœtal loss
Birth-weight				
1000 g (2 lb 3 oz) or more	130	13 (*10%*)	135	45 (*33%*)
2500 g (5½ lb) or more	117	9 (*8%*)	110	26 (*24%*)
White's classes				
A, B and C	74	5 (*7%*)	94	26 (*28%*)
D and F	56	8 (*14%*)	41	19 (*46%*)

* See footnote to table III

chemical control, (2) measures to prevent or correct œdema and hydramnios, (3) sex-hormone therapy, intramuscular stilbœstrol and progesterone given daily in increasing doses throughout pregnancy, (4) early induction of labour, with cæsarean section in 70% of cases; and (5) special care of the infant

White claims that her good results are due mainly to the prophylactic sex-hormone therapy In one of their recent series (Nelson et al 1953), consisting of 128 babies, weighing at birth 960 g (2 lb 1½ oz) or more, observed in 1950–52, the mothers were seen once or twice a week during the latter half of pregnancy, most often simultaneously by the physician and the obstetrician All the patients were admitted to hospital at the end of the 34th week (about 40 days before the calculated term) and remained in hospital until delivery Patients with complications were admitted earlier Class-A patients did not have hormone therapy and were allowed to go to term It was the intention to deliver all the other patients by the end of the 37th week, but 25% had to be delivered at the end of the 35th week or earlier

TABLE V—FŒTAL MORTALITY * FROM 1946 TO SEPT. 30, 1955, CLASSIFIED BY BIRTH WEIGHT AND RELATION OF DEATH TO LABOUR

Treatment	*Death before labour or of infants with birth weight 1000–1550 g (2 lb 3 oz – 3 lb 6 oz)*		*Birth weight 1600 g (3 lb 8 oz) or more and baby alive at onset of labour*		Total	
	No of babies	Fœtal loss	No of babies	Fœtal loss	No of babies	Fœtal loss
Long term	130	6 (*5%*)	124	7 (*6%*)	130	13 (*10%*)
Short-term	135	26 (*19%*)	109	19 (*17%*)	135	45 (*33%*)

* See footnote to table III.

The King's College Hospital series, consisting of 141 cases in 1949 (Peel and Oakley 1949) and 275 by June, 1953 (Oakley 1953), carried an unaltered over-all fœtal mortality of about 25% The patients attended the diabetic clinic and were treated as outpatients They were controlled by different, though fewer, doctors, but no attempt was made to bring the blood-sugar to the physiological level Pregnancy was terminated between the 33rd and 38th weeks, and in 75% of cases cæsarean section was done (Oakley 1953) In 56 of 129 cases treated between 1949 and December, 1953, stilbœstrol and ethisterone were given by mouth (Peel 1954) This hormone therapy was not thought to reduce the fœtal mortality Oakley and Peel have not reported their fœtal mortality classified according to the stage of pregnancy at which the patient first attended the clinic, but 18 5% of the infants born by cæsarean section died in the neonatal period (Oakley 1953)

The Medical Research Council's (1955) series was designed as a controlled trial of the value of giving stilbœstrol and ethisterone by mouth during pregnancy The series comprises 136 viable infants distributed among nine centres Apart from the hormone treatment and some general rules (termination of pregnancy between the 34th and 38th weeks by the method most desirable on obstetric grounds, and keeping the babies in oxygen tents for at least 48 hours after birth) the treatment was not strictly regimented The series was treated by different physicians, obstetricians, and pædiatricians Half the mothers were given hormones by mouth during pregnancy, and the average stay in hospital before delivery was 2 3 weeks The average weight of the babies at birth was about 3 2–3 3 kg (7–7¼ lb) The fœtal mortality (stillbirths and neonatal deaths within a month after delivery) was 25% in both groups

TABLE VI—FŒTAL MORTALITY * FROM 1946 TO SEPT 30, 1955, IN WHITE'S CLASSES B, C, AND D

Treatment	White's classes					
	B		C		D	
	No of babies	Fœtal loss	No of babies	Fœtal loss	No of babies	Fœtal loss
Long term	41	2 (*5%*)	30	3 (*10%*)	50	4 (*8%*)
Short term	44	18 (*41%*)	42	5 (*12%*)	37	18 (*49%*)

* See footnote to table III

Table VII compares the treatments given in Peel's 1949–53 series (Peel 1954), the Medical Research Council's (1955) series, the series of Nelson et al (1953), and our long term series Two factors common to the treatments of the two series—that of Nelson et al (1953) and our long-term series—with the lower fœtal mortality are: (1) one attending physician and good medical treatment during pregnancy ("treatment of every abnormality"); and (2) experienced obstetrical management and infant care by a few persons To get a low fœtal mortality it is unnecessary to do a lot of cæsarean sections or to give sex hormones We deliberately use the word "unnecessary" of sex-hormone therapy because we are not in a position to judge whether this treatment is possibly beneficial To test this a controlled trial would have to be made with material having the lowest fœtal mortality by the classical treatment, and at present there does not seem to be any need for such a trial

TABLE VII—COMPARISON OF SOME PUBLISHED SERIES

Series	Years	No of *cases*	Fœtal mortality (*%*)	Treatment during pregnancy			Rate of cæsarean section (%)	No of teams in obstetric and in infant care
				Sex hormones (% of cases)	Last months			
					Strict medical	No of physicians		
Peel (1954)	1949–53	129	27	43	—	Few	75	One
Medical Research Council (1955)	?	136	25	50	—	Several	?	Several
Nelson et al (1953)	1950–52	128	10	ab 95	— —	One	70	One
Present long term treated series	1946–53	130	10	0	— — —	One	18	One

extradural hæmorrhage, it indicates that a tentorial pressure cone is developing and the patient's condition often deteriorates very rapidly

As Lewin emphasises, a localised bruise or laceration of the scalp is a very useful guide in identifying which side a hæmatoma is on, in 21 of his patients there was a local injury over the hæmatoma He stresses the importance of careful examination of the scalp, and the search should be repeated on the operating-table after the whole head has been shaved. In most cases there is radiological evidence of a fracture overlying the hæmatoma, though occasionally there is none[29 30] X ray examination may also show displacement of a calcified pineal body, and this is of course most valuable evidence of a hæmatoma But even a centrally placed pineal body does not exclude a hæmatoma, since in Lewin's series there were 2 patients with central pineals, in each the extradural hæmatoma was in an unusual site, one in the posterior fossa and the other under one frontal lobe Most extradural hæmorrhages are in the temporal regions but occasionally they may be found, as in these 2 cases, in the posterior fossa or under the frontal lobes, and this is one of the main reasons for the high mortality, since the accurate diagnosis of bleeding in these sites may be very difficult Lumbar puncture is not a great help in diagnosis and has the very definite danger of precipitating a tentorial pressure cone, puncture was performed in 13 of Lewin's patients and in 5 the pressure was normal It is by no means certain why the pressure is normal in the presence of a large extradural clot, but it is important to realise that it may be so, otherwise the possibility of a hæmatoma may be dismissed in spite of a suggestive clinical picture Schneider and Tytus[24] drew attention to another pitfall in diagnosis when there is profuse cerebrospinal rhinorrhœa or otorrhœa after a head injury extradural hæmorrhage may produce very little immediate signs of rising intracranial pressure

As Lewin observes, the important clinical pointers to the presence of a hæmatoma are deterioration in the level of consciousness once improvement has begun, the onset of symptoms and signs of cerebral compression, and the development of fresh neurological signs

COOPERATION IN TREATMENT OF CANCER

THERE has in recent years been a good deal of discussion about the best methods of securing cooperation between physicians, surgeons, and radiotherapists in cancer treatment In many centres the days are passing when a patient with cancer tends to be treated rather by the method most familiar to the first specialist he sees than according to his need, but the resources for investigation and treatment still differ widely between one hospital and another Joint cancer consultation clinics are greatly aiding selection and combination of treatment and, through joint follow-up clinics, have provided valuable opportunities for specialists to see what can be achieved by methods other than those in which each is expert A further advantage has been the concentration of clinical material and specialist experience for teaching purposes

In 1944 an interesting experiment on these lines was organised by the Royal Marsden Hospital (then the Royal Cancer Hospital) Joint cancer consultation clinics had been set up within the hospital just before the war and these were later extended to include other hospitals, starting with the Brompton Hospital for Diseases of the Chest and the Chelsea Hospital for Women, its immediate neighbours with which there had been a long unofficial association By 1945 these clinics had been extended further to include the Moorfields, Westminster, and Central Eye Hospitals, and the Royal National Throat, Nose, and Ear Hospital For four years the Royal Free Hospital cooperated in the scheme until its own radiotherapy department was re established, and another arrangement existed with the Princess Beatrice Hospital until it became part of the Westminster Hospital group At present the group of hospitals running joint cancer consultation clinics consists of the Brompton Hospital for Diseases of the Chest, the Chelsea Hospital for Women, Fulham Hospital, Moorfields, Westminster, and Central Eye Hospitals, the Metropolitan Ear, Nose, and Throat Hospital, the National Hospital, Queen Square (together with the Atkinson Morley Hospital and the neurosurgical unit of the Hospital for Sick Children, Great Ormond Street), the Royal National Throat, Nose, and Ear Hospital, the Royal Sussex County Hospital, St Mary Abbot's Hospital, St Peter's, St Paul's, and St Philip's Hospitals, St Stephen's Hospital, and the West End Hospital for Nervous Diseases

Over 1000 patients a year are now seen at the joint clinics held between these hospitals On May 11 and 12 this group is to hold its first general meeting, which will be open to the medical profession[1]

On Friday, May 11, starting at 10 A M, at the Royal College of Surgeons there will be a series of reports, mostly from the special postgraduate hospitals cooperating in the scheme, giving some account of the working of the joint consultation clinics of the way in which surgery or radiotherapy have been selected or combined in the treatment of special groups of patients, and of the results obtained over the past twelve years There will also be accounts of some of the joint clinical research projects initiated within the group An exhibition illustrating the work of the clinics will be on show in the council room An account will also be given of the cooperating hospitals cancer registry which has been set up to provide a direct registration and statistical service to each of the cooperating hospitals The scheme is designed to obtain complete cancer registration within this group of hospitals and for the registry to provide each individual hospital, and indeed each individual member of each staff, with any recorded information they may require about any group of patients seen, including the follow up

On Saturday, May 12, the Royal Marsden Hospital will be open from 10 A M to 1 P M, and demonstrations of special facilities available to the group and some of the clinical investigations, treatment, and research carried out will be on view

SOCIETY OF MEDICAL OFFICERS OF HEALTH

NEXT week this society is celebrating the centenary of its foundation At the opening meeting on Tuesday afternoon at B M A House Dr Huntington Williams, health commissioner of Baltimore, will deliver a message from the American Public Health Association and himself receive the honorary fellowship of the society from Dr C F White, the president The following day at 2 15 P M open fora will be held on public health problems of today, and at 4 30 P M Lord Adrian, O M, will deliver an oration on the Organisers of Health In connection with the celebrations, exhibitions will be held at the Wellcome Historical Medical Museum and the London School of Hygiene and Tropical Medicine The Lord Mayor and corporation of London are giving a banquet, and the London County Council and the British Medical Association receptions, in honour of the society

THE INDEX and title-page to Vol II, 1955, which was completed with THE LANCET of Dec 31, is to be issued next week A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now

TABLE II—PLASMA-VITAMIN-A LEVELS IN MARASMIC INFANTS

Case no	Disease	Age (mos)	Weight (kg)	Plasma vitamin A (I U per 100 ml)			
				Fasting (duplicates)		4 hours after the standard oral dose of vitamin A (duplicates)*	
1	Gastro-enteritis	1	3 1	95	110	165	150
2	Gastro-enteritis	2	3 6	50	—	415	—
3	Bronchitis	3	3 1	135	210	755	765
4	Mongol	4	4 0	Nil	—	Nil	—
5	Feeding disorder	4	2 6	130	115	105	100

* The standard oral dose of vitamin A was 12 500 I U vitamin A palmitate in arachis oil per kg of body weight

level after vitamin-A concentrates had been withheld for at least forty-eight hours

The plasma-vitamin-A level was estimated by spectrophotometry by the method of Bessey et al (1946) modified by the use of 2-ml plasma samples and the substitution of benzene for the kerosene-xylene mixture used to extract the vitamin A from the plasma The spectrophotometric readings were converted into I U of vitamin A by reference to a standard curve prepared from pure solutions of vitamin-A acetate in benzene

Results

The results are shown in tables I, II, and III The infants with idiopathic hypercalcæmia had higher fasting plasma vitamin-A levels than either the infants marasmic from other causes or the healthy children, they also had higher plasma-vitamin-A levels four hours after the standard test dose Cases 12 and 13 are exceptions, but beginning recovery from the disease may explain their normal results, they had been under medical supervision for four months and five months respectively, and both were starting to thrive when their vitamin-A levels were estimated

TABLE III—PLASMA-VITAMIN-A LEVELS IN INFANTS WITH IDIOPATHIC HYPERCALCÆMIA

Case no	Age (mos)	Weight (kg)	Serum calcium * (mg per 100 ml)	Plasma vitamin-A (I U per 100 ml)			
				Fasting (duplicates)		4 hours after the standard oral dose of vitamin A (duplicates) †	
6	8	5 6	15 5	245	280	3590	3480
7	14	6 3	15 3	280	430	940	905
8	11	7 0	15 2	225	210	1320	1365
9	8	6 6	15 1	365	435	1720	1810
10	4	5 4	14 8	355	355	3230	3375
11	10	5 8	13 5	255	—	1215	—
12‡	9	5 5	13 3	160	155	605	595
13	7	6 5	12 4	120	235	975	1095

* The serum-calcium levels were estimated within a few days of the plasma vitamin A levels

† The standard oral dose of vitamin A was 12 500 I U of vitamin-A palmitate in arachis-oil per kg of body weight

‡ This patient was given 20,000 I U of vitamin A per kg of body weight

The plasma vitamin-A levels of the infants with idiopathic hypercalcæmia were compared by statistical methods with the corresponding levels, of the healthy children These calculations showed that both the fasting levels and the levels four hours after the standard test dose were significantly higher in the infants with idiopathic hypercalcæmia The mean plasma-vitamin-A levels are shown in table IV The calculations were made only on the duplicate estimations to eliminate the variations between children—e g, a variation from an average value of 3545 I U per 100 ml of plasma four hours after the standard test dose in one infant with idiopathic hypercalcæmia to 600 I U per 100 ml of plasma in another

Discussion

Aron (1949) has shown that the plasma-vitamin-A level of a healthy person is kept almost constant despite variations in the dietary intake of the vitamin He considers that this is due to the existence of a mechanism for controlling the level of vitamin A in the plasma, and that the liver plays an important rôle in this regulatory process In apparently healthy infants a high oral intake of vitamin A daily for several weeks will raise the plasma-vitamin-A level, but this returns to normal within a few days of reducing the intake to that contained in a normal diet (Josephs 1944) None of the infants with idiopathic hypercalcæmia in the present series had a high vitamin A intake immediately before the date on which the estimations were made, hence vitamin-A overdosage was not responsible for the high fasting plasma-vitamin-A levels of these infants Various diseases are associated with alterations in the plasma-vitamin-A level, which is low in febrile states (Clausen and McCoord 1938, Lindquist 1938) whereas it is high in chronic nephritis and in the nephrotic syndrome (Clausen and McCoord 1938) Idiopathic hypercalcæmia appears to belong to this group of diseases Aron (1949) has suggested that such diseases interfere with the mechanism normally responsible for maintaining a constant plasma-vitamin-A level

TABLE IV—MEAN PLASMA VITAMIN-A LEVELS
(Calculations made only on duplicate estimations)

—	Plasma vitamin A (I U per 100 ml)	
	Fasting	4 hours after the standard oral dose of vitamin A*
Infants with idiopathic hypercalcæmia	275	1786 1
Healthy children	130 6	648 1

* The standard oral dose of vitamin A was 12 500 I U of vitamin-A palmitate in arachis oil per kg of body weight up to a maximum of 250 000 I U of vitamin A

McCoord et al (1948) showed that, after a standard oral dose of vitamin A, the rise in the plasma-vitamin-A level of malnourished infants is smaller than in healthy infants This finding has been confirmed in the present investigation It contrasts with the greater than normal rise observed in the infants with idiopathic hypercalcæmia The height to which the plasma vitamin-A level rises after a large oral dose of vitamin A must depend on the rate of absorption and the rate of storage It is impossible, however, to determine from the present data whether there is increased absorption or diminished storage of vitamin A in idiopathic hypercalcæmia

A disorder of vitamin-A metabolism similar to that found in idiopathic hypercalcæmia has been described in the nephrotic syndrome (Kagan et al 1950) Moore and Sharman (1951) have drawn attention to this and to other evidence which appears to connect urinary diseases with vitamin-A deficiency and with abnormalities of vitamin-A metabolism It is of interest, therefore, that idiopathic hypercalcæmia, in which renal calcinosis sometimes develops, provides a further example of this association

Since vitamins A and D are both fat soluble, an abnormal vitamin-A metabolism in idiopathic hypercalcæmia is a further indication that vitamin-D metabolism may be abnormal in infants who develop this syndrome

Summary

In 8 cases of idiopathic hypercalcæmia the plasma-vitamin-A levels were estimated before, and four hours after, a standard oral dose of vitamin A The results

of hospital privileges, but British patients expect to be referred to specialists for major procedures and they do not think less of their own doctor because of this. In contrast, general practitioners in small towns in Western Canada do much surgery, partly because this is often essential, and partly on the assumption that their patients expect it of them. A demand by the general practitioner for hospital work or some form of specialised practice is reasonable if this will fill a local need, but it should not be allowed to prevent him giving adequate time to the rest of his patients.

The general practitioner is taught as a student principally about diseases which are best treated in hospital, and he tends to think that hospital practice is the most important aspect of medicine. This is bad because he will be frustrated at being unable to practise the sort of medicine he was taught, and also because, in his quest for hospital privileges and impressive equipment, he may be diverted from his rôle of adviser and friend to his patients.

The overwhelming part played by the hospital and its specialist staff in our education deeply affects our ideals of medical practice. We spend so much of our early career inside one that it is difficult for us to see that a hospital in relation to present day medicine as a whole is only a specialised instrument—certainly a very large, important, impressive, and expensive instrument, and for this last reason one which must be reserved as far as possible for patients in a phase of their illness in which it is needed. Since the hospital is the scene of so much impressive, and by and large successful, medical endeavour, the student may be forgiven for thinking that it is the whole world of medicine that matters, in which the consultants are the heroes. The consultants have not been assiduous in discouraging this view. It is not surprising, therefore, that the doctor graduates as an indifferent specialist rather than as a general practitioner, and that he retains a respect for hospital privileges, access to impressive equipment, and technical skill.

The original concentration of medical teaching in hospital was necessary to break the unscientific traditions of the apprenticeship system, which still is often perpetuated in assistantships. But general practice has become increasingly effective, recently aided by chemotherapy and by diagnostic facilities such as the Public Health Laboratory Service. The extension of medical care to the whole community has only been possible through a great increase in the effectiveness of general practice ; similarly, the economical use of hospitals and the extension of medical care to the whole community are possible only because of the general practitioner's work outside hospital. If general practice is limited in scope, it is because medical education did not prepare the present generation of doctors for this type of work.

Introducing students to general practice is still in the experimental stage, and although this has been under way for some time in the United States and Scotland, English and Canadian universities seem to be approaching the problem more cautiously ; the colleges of general practice in England and Canada should speed this scheme.

The general practitioner has a continuous responsibility for his patients, although for a phase of an illness they may be in the hands of a specialist. In *fulfilling this* responsibility he encounters organic disease he knows how to diagnose and treat rationally, disease he can diagnose but must refer for treatment (which if he conducts his practice well need not constitute more than 15% of his cases), organic disease which neither he nor anyone else can do more than palliate, many disorders of a probable organic origin which do not fit into any distinct syndrome, and 30% or so ailments largely psychogenic. This is a sufficient challenge to any man's scientific and humane abilities for which he needs as much time as he can gain. Unfortunately his training has prepared him very unevenly for these various types of case. The young general practitioner not unnaturally tends to pay most attention to the types of case he has been taught about and is apt to think that patients who do not have syndromes he recognises are not really ill. Yet if he attempts to select those he will help and those he feels not morally entitled to help, he creates needless difficulty for himself and unhappiness and hostility in those rejected. Treatment of course does not necessarily consist in granting all demands, but may consist in a firm but polite explanation why none is necessary.

Until he has had much experience he tends to judge the quality of general practice by specialist *criteria*, and feels that he should be using methods appropriate to dealing with disease at the specialist level. Since he has to deal with comparatively large numbers of patients, inevitably part of his work consists in "screening" or selecting *those most suitable for specialist treatment*. This should cause no shame and is an important part of his function as part of the medical team. Specialists appreciate the general practitioner who uses them efficiently on behalf of his practice.

Conclusion

No rigid pattern for general practice should be devised. The general practitioner's work is decided by the needs of the society he serves, but his ability to fill this need is impaired if his *training gives him too* rigid a conception of medical practice ; for instance, in the small towns of Western Canada he is required to do much emergency surgery which in Britain he is not. General practice fills the very big gap between the medical needs of the *community and the capacity of hospitals and specialists* to meet them.

More doctors should be encouraged to become general practitioners ; and practices should be made smaller. They could then spend a greater amount of time in *consultations (at present brief* by Canadian standards) as friend and adviser to their patients.

THE EFFECTS OF SEPARATION FROM THE MOTHER IN EARLY LIFE

D. H. STOTT
M.A. Camb., Ph.D. Lond.
RESEARCH FELLOW,
UNIVERSITY OF BRISTOL INSTITUTE OF EDUCATION

LARGELY through the work of Dr. John Bowlby, there has been much discussion in recent years about how children's personalities may be affected by stays in institutions or in hospital during early life. For the present study we chose, from among 141 backward children, the 25 who had been separated from their mothers for at least ten weeks during their first *four* years of life. Actually the average length of their separation was *over eighteen* weeks in the first year, nearly seventeen in the second, and for the whole of the first four years no less than seventy two weeks, or about one third of their lives up to that point.

Assessments of their emotional development were provided by their teachers on the comprehensive Bristol Social Adjustment Guide, and comparable information as to their domestic behaviour was obtained from interviews with the mothers or with the staff of institutions. Since emotional factors are very important for the understanding of backwardness, indications of the mutual affection between mother and child had been

BIOCHEMICAL DATA AND BLOOD-PRESSURE

normal. At no time did the serum potassium level rise above 6 m eq per litre (normal = 4–5 m eq per litre) The blood-urea level was 56 mg per 100 ml on the twentieth day Since the anæmia still persisted (Hb 8 6 g per 100 ml) and Heinz bodies and fragmented red cells were still present, the patient was given a further transfusion of 1000 ml of packed red cells, which increased his Hb to 10 4 g per 100 ml

Convalescence was complicated by a recurrence of acute bronchitis and by a deep vein thrombosis in the left calf, from both of which he recovered rapidly He went home thirty three days after admission, and when seen again a month later he was very well His blood urea level was then 35 mg per 100 ml. and Hb 13 3 g per 100 ml, and his erythrocytes were morphologically normal

Discussion

The fatal dose of potassium chlorate varies greatly A. R Cushny (Grollman and Slaughter 1947) said that 1 g had proved fatal in a child, whereas adults had swallowed 40–50 g without developing serious symptoms, he remarked that poisoning was more likely in nephritics than in healthy people Witthaus (1911) stated that the minimum lethal dose was 12 g for an adult, 5 g for a child, and 1 g for an infant

The toxic effects of orally administered potassium chlorate are due to three distinct causes

(1) A non specific local action characterised by immediate nausea, vomiting, and mild diuresis

(2) The effect of the potassium ion on the myocardium, leading to hypotension, bradycardia, heart-block, and, in fatal cases, ventricular fibrillation

(3) The effect of the chlorate⁻ion, which denatures Hb with the production of Heinz bodies, and lyses the erythrocytes This reduces the oxygen-carrying capacity of the blood The hæm of the Hb thus liberated becomes attached to serum albumin, forming the brown pigment methæmalbumin (Fairley 1941), which is probably excreted as bilirubin by the liver Part of the liberated Hb may be excreted unchanged in the urine

The mass destruction of red cells has consequences similar to those found in the syndrome variously known as pigment nephrosis, transfusion kidney, tubovascular syndrome, and renal anoxia syndrome (Maegraith et al 1945) Potassium chlorate is metabolised slowly, and about 90% is excreted unchanged in the urine (Grollman and Slaughter 1947) It thus remains in the body during any period of anuria and continues hæmolysis

Acute potassium-chlorate poisoning has therefore a very characteristic course It begins with an attack of vomiting, followed by transient cyanosis due to the formation of Heinz bodies The onset of hæmolysis is rapid, and the consequent anæmia and jaundice are severe by the third day, when Hb, bilirubin, and urobilin are present in the urine and the risk of anuria is greatest Hæmolysis is likely to continue for several days, even after the flow of urine has been restored

Potassium-chlorate intoxication thus provides another example of oliguria due to renal damage Bigby and Avery Jones (1949), Bull and Joekes (1949), and Discombe (1954) have all emphasised that patients with this form of acute oliguria usually recover, provided that they are not *given* potassium salts, and that overloading of the circulation with parenteral infusions of saline solution, glucose, sucrose, or sodium sulphate is avoided Evans et al (1953) have pointed out that hyperkalæmia is the common cause of death, and that it is due to the breakdown of endogenous intracellular protein This process is accelerated by pyrexia, infection, and semistarvation, and is minimised by the prevention and cure of secondary infection and by providing a protein-free high-calorie diet (Bull 1955) These principles were successfully used in treating the present patient Since at no time did his serum-potassium level rise above 6 m eq per litre, ion exchange resins in the sodium cycle, as advocated by Evans et al (1953), were not used The anæmia, which may further impair renal function, was treated with transfusions of packed red cells Removal of the potassium-rich plasma lessened the danger of hyperkalæmia and averted disturbance of the fluid balance Control of the patient's respiratory infection and oral sepsis was achieved by systemic chemotherapy In retrospect such high dosage was not required in the presence of poor renal function 1 mega-unit of penicillin G given intramuscularly daily is all that is required (Bull 1955) Efforts to promote renal activity with oral potassium citrate and parenteral infusions were avoided because they are useless and indeed dangerous (Discombe 1954)

Summary

A case of Heinz-body hæmolytic anæmia following the accidental ingestion of potassium chlorate is reported

The hæmolysis persisted for twenty days and was complicated by oliguria lasting nine days

Potassium chlorate poisoning is yet another cause of renal damage with oliguria best treated by the Bull regime

I wish to thank Dr K. P Bull for permission to publish and for his encouragement, and Dr George Discombe and Dr Clifford Hoyle for invaluable advice and criticism in the preparation of this paper

them as maladjusted children It is significant that all these again were unnaturally helpful towards their mothers There were also powerful additional factors, other than early illness or separation, which could account for their unsettledness One of these children was the twin of a girl in the well-adjusted group His unsettledness is of theoretical interest in that besides being badly scalded as an infant he suffered distressing experiences during the nine months' separation, while his stable girl-twin did not During his stay in a residential nursery, he was removed to hospital because of ringworm, and underwent what to a toddler must have been the terrifying ordeal of having his head shaved without his mother or other familiar person being there to comfort him

Another of this unsettled group well illustrates how the lack of a mother in the first years of life, while not making the child into a completely "affectionless character," may provide it with a mechanism by which it can cut itself off from affection This withdrawal will not be the dominant element in the personality unless the child feels itself unwanted and unloved in its contemporary life, but it reverts to a defensive attitude of "affectionlessness" when punished or is otherwise in disfavour

The boy in question was placed in an institution when 3 weeks old, and remained there until he was 3 The mother could not bear to visit him during most of this time, but accepted him gladly when, on her marriage, she had him to live with her When, preparatory to his homecoming, she visited him, he was "petrified of anybody and stayed in the middle of the room and screamed" At home "he was not a cuddly child, you couldn't pick him up on your knee, he didn't want it" Her constancy, however, won him over, and the only complaint she made of his home behaviour was that he had terrific tempers and got stubborn "for really nothing at all" This underpattern of withdrawal shows itself occasionally in children who have had to do without a mother in their early years, when they are crossed they go into a stubborn "freeze"

The Maladjusted

So far 21 of the 25 children are accounted for, which leaves only 4 really maladjusted ones One of these was a foundling child who had been in institutions all her ten years of life Little can be said of her except that she represented that mixture of hostility and anxiety for acceptance which is found as a type of maladjustment just as much outside as inside institutions

The second girl was put in an institution when she was $3^1/_2$ for some two years her mother was an invalid who later died After that she was passed back and forth among various relatives, with the result that she became virtually unmanageable, and could not be kept in a residential school, in a mental defectives' institution, or with a foster-mother—until finally an aunt by marriage took pity on her and heroically showed herself determined to keep her This child, after a year of this latter day security, was very friendly and attention seeking, but would become stormily defiant at the slightest provocation, and stole frequently as the pronouncedly anxious-hostile type are inclined to do

The third child was away from her parents, either in hospital or evacuated, until she was nearly 6 Her main preoccupation was expressed in her repeated question to her mother "If I am not a good girl will I have to go away?" This child was also of the defiant hostile-anxious type

The common element in these three girls' lives was that they had no permanent mother figure during their childhood, but had to make do with such affection as was offered by whoever was in charge of them for the time being Even then they were not affectionless they had a burning need for affection, alongside the rejection and hostility which they always kept ready at hand in case their need for love was not met Their maladjustment was the imprint upon them, not of any specific phase in their lives, but of their motherless state over large stretches of it

The last child comes nearest to the type of the "affectionless character" He had trained himself never to seek sympathy, and so he never cried when he hurt himself His mother often threatened to have him put away, especially over his stealing, in which he indulged shrewdly both at home and at school, but he showed no distress at the threat He was one of those children who, although reputedly of dull intelligence, could "tell lie after lie and look you full in the face" How is such a character made? His early history did not differ greatly from that of the other maladjusted and unsettled children Being exceedingly puny and underweight at birth he was retained in hospital for the first three months of his life When, at that age, he was returned to his mother she put him in a day nursery because she was in residential service At 1 year he had another three months in hospital with meningitis When he was 6 or 7 his mother, as she said, "tried to get him away but we could not do anything about it He was a drawback to me working in service" All this was related in front of the child in a matter of fact way It was evident that the child must have heard all the details of the steps she was taking to get rid of him Thus was progressively destroyed his faith in her loyalty as a mother It was this unnatural situation during the years between 6 and 9, rather than his early experience, that was making him seek refuge in affectionlessness But he helped his mother with the washing up, swept for her, and "starts to clear the table even before you have finished"—which shows that the term "affectionless character" in this as probably in most cases is an over-simplification, about which caution must be exercised in the diagnosis of maladjustment

Separation and Security

What conclusions can be drawn as to the effects upon these 25 children of long early separation from their mothers? The only definite one is negative in itself the separation certainly does not have the dire consequences that have been supposed, for, if it did, there would have been more than 4 maladjusted children among the 25 considered Furthermore their maladjustment, and the unsettledness of 5 of the other children, can be accounted for by a succession of other factors in their later lives The formula for maladjustment is to deny the child family security More exactly, this means that for stability of character a child needs to feel that it has reliable—that is to say permanent—human attachments It is not affection in the sense of fondling or treats or indulgence that counts, but affection in the sense of a loyalty which induces the parent or other adult to stick to the child through thick and thin and neither relinquish the child to other care nor threaten or appear likely to do so A child who has never enjoyed these loyalties from any adult at any time will become the so called "affectionless character"—the toughened rogue without loyalty or sense of decency But such children are exceedingly rare, and, certainly at the pre adolescent stage, the loss of feeling will still be incomplete and there will be at least a modicum of anxiety for acceptance

There is nevertheless some evidence that long separation can have a detrimental effect upon a child's emotional development In the total sample of 141 there were 9 children who had been separated a month or more under 4 years of age without, so far as was known, any serious illness or its equivalent Of these 5 were maladjusted (3 of them being mentioned above in the group of 25 separated ten weeks or more), and 4 were unforthcoming The quantitative evidence as to the effects of separation as such is thus scanty, but the indications

Relief of Symptoms

WALTER MODELL, F.A.C.P., associate professor of clinical pharmacology, Cornell University Medical College Philadelphia and London W B Saunders 1955 Pp 450 56s

IT is perhaps true, as Dr Modell believes, that, with the great advances in curative medicine, the relief of the patient's distress has come to be neglected Certainly, the proper use of symptomatic treatment calls for skill and judgment, and this book provides useful help It is written informally and readably, and reflects the wide practical experience of its author

The opening chapters discuss the general principles involved in the relief of symptoms and they contain much sound advice Important symptoms are then dealt with individually A final chapter describes the uses of cortisone and gives warning of its danger as a masker of symptoms There is a refreshing clarity and briskness in the writing

As a pharmacologist, the author is able to speak with authority about the use of drugs, and he mentions many substances recently introduced It is interesting to note that heroin receives little attention, either in the chapter on cough or elsewhere

Arthroplasty

SIR J D BUXTON, F.R.C.S., consulting orthopædic surgeon to King's College Hospital London Pitman Medical Publishing Co 1955 Pp 126 30s

WRITING in an easy and direct style, Mr Buxton gives an excellent historical review of the work on arthroplasty of all joints over the past fifty years, but it is only where the hip is concerned that he goes into sufficient detail to be of real help to the orthopædic surgeon He was one of the first in this country to make extensive use of the 'Perspex' femoral head, experience of this operation dates only from 1950 and recent reports on the late results, at least in this country, have shown that the durability of the perspex head is much less than had at first been hoped The pendulum is now swinging back towards the old operations, such as McMurray's osteotomy and Girdlestone's pseudarthrosis, where the maintenance or creation of a mobile hip is essential, and the indications for the Judet procedure are becoming relatively restricted

Nevertheless, this is an interesting monograph which will be enjoyed by many It is excellently produced and embellished with illustrations of the highest class, and there are very useful chapters on rehabilitation and record charts

Applied Medical Bibliography for Students

WILLIAM DOSITE POSTELL, medical librarian and professor of medical bibliography, Louisiana State University School of Medicine, New Orleans Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 142 32s 6d

SOME instruction in the use of libraries, much of it informal, has been given in America and in this country for many years, but there are very few medical schools in which medical bibliography has managed to win its own little corner in the curriculum Mr Postell, a librarian of great experience, has embodied the substance of his lectures on this subject into a book which medical students (and indeed all users of medical libraries) may read with interest and profit

The book starts with an account of the evolution of medical literature, which includes an excellent chapter on the history of medical periodicals Information is then given on the arrangement of the library, the catalogue, some of the classification schemes in common use, basic reference works, bibliographical tools, and the periodical collection The final part contains advice on medical writing and on the principles of bibliographical citation

There are few questionable statements of fact, but it is wrong to say that most of the earlier printed books were on parchment or vellum, and the author is also mistaken in his belief that a sheet folded four times is known as a quarto and one folded eight times as an octavo The information concerning the *Medical Directory* is out of date and the list of bilingual medical dictionaries is inadequate

A more serious criticism is that Mr Postell does not always seem to know whether he is writing for the student of medicine or for the student of librarianship Thus, the instruction regarding alphabetisation in catalogues may mislead the medical reader into expecting uniformity in treatment which he will certainly not find in practice Much of the space devoted to medical writing could have been more profitably given to certain forms of literature (such as governmen publications, theses, reprints, and congresses) which presen special difficulty to the inexperienced reader A more precis evaluation of some of the reference sources mentioned, and hints on the extent and peculiarities of the "literature" in the special departments of medicine would have added considerably to the value of the work The procedure fo looking up references on subjects such as tuberculosis o cancer is quite different from that for the "rare" diseases but distinctions of this kind are not mentioned

The difficulty of seeing the problems of bibliographica research from the reader's point of view is very great and although the author has compressed much valuable information and advice into a short book it can hardly be said that he has reached the heart of the matter

Die Hand des Kranken

Prof Dr MAX BURGER, Direktor der medizinischen Universitätsklinik Leipzig Munich Lehmanns 1956 Pp 445 DM 37

To doctors, as to artists, the hand must always be o interest, for it has much to tell the discerning physician Professor Burger has done good service in collecting so much of value in this unusual and stimulating book

He has not limited himself to mere lists of pathologica states of the hand, though there can be few if any of these that he has overlooked He has also described the norma hand, its anatomy and physiology, and added many interesting sidelights on such things as finger prints palmistry and even the deaf-and dumb language In his description of disorders and abnormalities of the hands he gives brief accounts of the general diseases underlying them, and the many bodily change in which the hand takes part The book is beautifully illus trated by some 200 pictures, mostly photographs and these alone tell a remarkable story of the manifold diseases of the hand.

No-one reading this book will fail to find much of interest in it—perhaps much that he has not known before

Thallium Poisoning

J J G PRICK, professor of neurology and psychiatry University of Nijmegen, W G SILLEVIS SMITT, professor of neurology, University of Utrecht, L MULLER, industrial physician, Enschede The Netherlands Amsterdam Elsevier London Cleaver Hume Press 1955 Pp 155 19s

THALLIUM is the active principle of many rat poisons and is easily obtainable In Great Britain all thallium salts are schedule-1 poisons and their sale is strictly controlled, but on the Continent thallium is rapidly superseding arsenic as the most common means of murder by poisoning This monograph was written because the symptoms and signs of thallium poisoning are not well known.

The symptoms are acute gastro intestinal upsets followed by signs of renal damage and peripheral neuritis If death does not occur in the acute stage, the peripheral neuritis progresses rapidly and baldness occurs after about twelve to fourteen days A butterfly shaped seborrhœic rash may develop on the face, and semilunar-shaped areas of discoloration of the nails may be seen

Professor Prick and his colleagues include in this useful study accounts of clinical cases, necropsy findings, and the results of animal experiments. The photographs of patients and photomicrographs of pathological tissue are of a high standard

Chirurgie du corps thyroide

SYLVAIN BLONDIN, chirurgien de l'Hôpital Beaujon Paris Masson. 1955 Pp 292 Fr 2600

THIS book is one of a series of surgical monographs edited by Professor Mondor The text is based throughout on the author's personal experience, sustained by a review of the literature which appears rather sketchy so far as British and American authors are concerned Operative procedures are described, though not in great detail The author has a strong preference for the use the greater will be the blow if the family loses its "mother." To a group of normal or stabilised children such a change can probably be overcome without harm, but for a maladjusted child, to take away the woman in whom it has learnt to trust may be absolutely disastrous. Such children should be placed in family groups which are likely to have a permanent mother-figure.

Assessment

The precise assessment of the influence of the events of early life upon emotional development obviously depends upon our having the means of diagnosing the nature and degree of maladjustment. In the past we have had perforce to rely upon subjective clinical assessments. These, however, are unreliable because they are weighted first by the interpretative preferences of the individual clinician and secondly by the fashion of the times. For example, psychopathic personalities and affectionless characters are at present being over-diagnosed. An alternative, and more objective, means of assessment has proved successful in the Bristol studies. This asks *the observer to furnish only data as to the child's* behaviour and attitudes, the interpretation of the latter being limited to a recognition of elementary emotional expression. *It has been found that the behavioural* data thus provided fall into fairly clear syndromes, indicating the existence of a small number of general maladjusted attitudes which serve as a basis for the diagnosis of maladjustment.

Summary

This has been a study, based on the case histories of backward children, of the effects of early adverse factors upon personality-development, with special reference to separation from the mother.

The mere fact of separation had a markedly small specific effect, but it contributed to unsettledness or unforthcomingness when other adverse factors were present. With short separation, the attendant circumstances of the separation and the maternal care received on return home were seen to be more important than the separation in itself.

The preventive indications are that, where a child has to undergo painful or frightening treatment, the mother should enter hospital with the child; for other hospital treatment frequent visits should suffice, together with guidance to the mother about the homecoming.

The minority of maladjusted children in the group of "separateds" owed their condition in the main to lack of a permanent parent figure throughout large parts of their lives, including their contemporary situation. Separation could predispose to "affectionless character," but this is due to a lack of maternal loyalty throughout life.

The most striking positive finding from the point of *view of personality-development was the high proportion* of early illness among the unforthcoming children. This was a general state of anxiety seen as chronic lack of confidence and over attachment to the mother. To this separation was only a minor contributory factor.

The Wider World

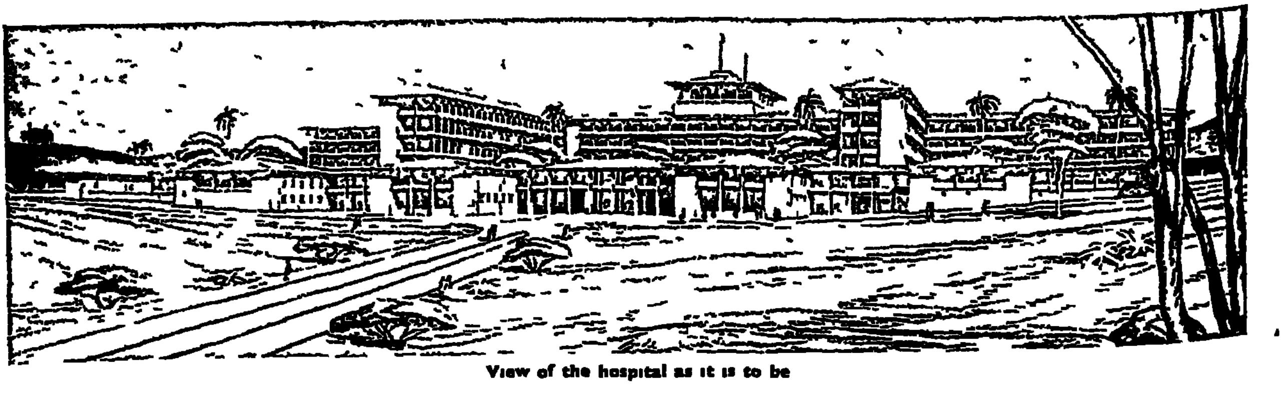
IBADAN

The New University College Hospital

Ibadan, visited by the Queen and the Duke of Edinburgh towards the end of their tour of Nigeria, is one of the most remarkable cities in Africa. Capital of the Western Province, with a population of more than half a million, it is the fourth or fifth largest city in the whole continent. But it is not so much for its size that Ibadan is likely to play an increasingly important part in the world as for its development in the past decade as a university town and a centre of African learning.

Since the late war, Nigeria has made notable progress alike in the political, the economic, and the educational fields. Politically, Nigeria is now a Federation with three component regions and the Trust Territory of the Cameroons. Both in the regions and at the centre political power is very largely in the hands of Nigerian ministers. Mainly because of favourable prices for produce the post-war period has been one of relative prosperity with expanding public revenues and much development both in the public and private sectors. But here, as elsewhere, civilisation and modern methods of communication have outstripped the available technical resources, with the result that the recruitment of trained professional people—always a difficult problem—presses with increasing urgency as the country advances. In particular Nigeria has a great need for doctors, of whom there are only 509 in the whole country, and it was the recognition by the Elliot and Asquith Commissions, whose reports were published in 1945, that the only solution of the problem lay in training Nigerians for positions of responsibility in Nigeria itself, which led to the founding at Ibadan in 1947 of a University College with faculties in arts, science, agriculture, and medicine.

Housed temporarily at first, the University College now has a fine new site just north of Ibadan with striking modern buildings erected at a cost of over £2½ million. But though the other faculties were soon well established, that of medicine had many difficulties to face. From its inception the University College was in special relationship with the University of London, which means that, with modifications to meet particular Nigerian requirements, the students are prepared for London degrees—an essential, in the initial stages, for recognition by the General Medical Council and the acceptance of training at Ibadan as the equal of that elsewhere. This arrangement, however, valuable though it is, brought immediate troubles to the young medical school, for the standards of London are high; and, though the facilities for preclinical training were soon recognised as adequate,

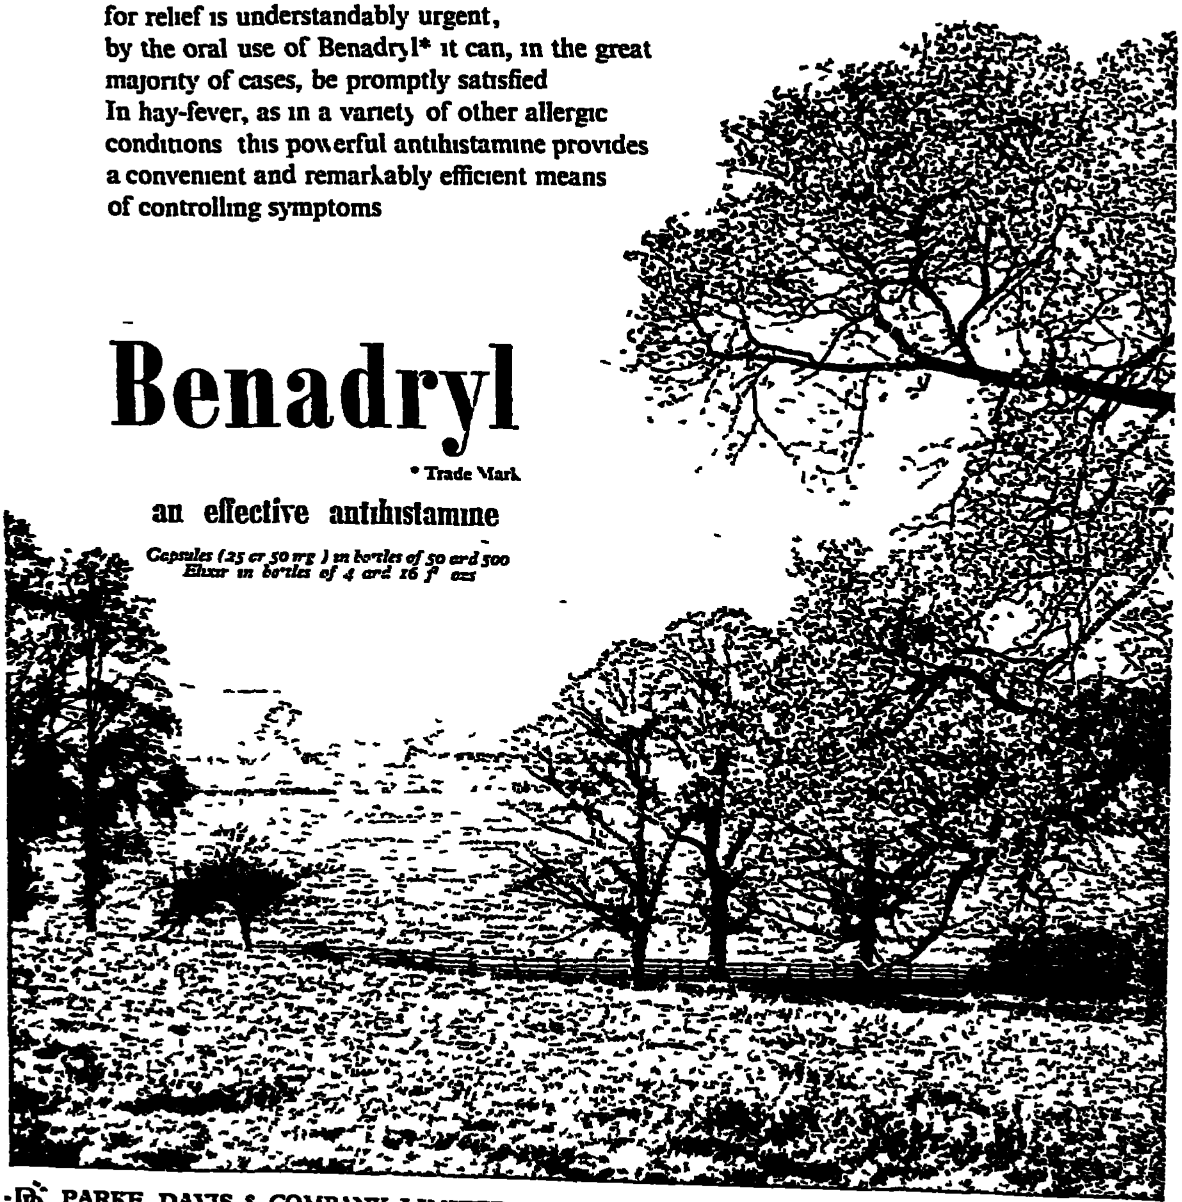


View of the hospital as it is to be

Nothing so active is as that which least seems so

Francis Thompson

A peaceful countryside scene but an active source
of intense discomfort for all those susceptible
to hay-fever, for now is the time of the year when
invisible air-borne pollens begin to take their toll
Incapacitated by continual weeping sneezing
and nasal congestion, the hay-fever patient s desire
for relief is understandably urgent,
by the oral use of Benadryl* it can, in the great
majority of cases, be promptly satisfied
In hay-fever, as in a variety of other allergic
conditions this powerful antihistamine provides
a convenient and remarkably efficient means
of controlling symptoms



Benadryl

Elixir in bottles of 4 and 16 fl ozs

PARKE, DAVIS & COMPANY, LIMITED (Inc U S A) HOUNSLOW, MIDDLESEX Tel Hounslow 2361 stimulate entry into the profession and lay a firm foundation for the country's medical future

Most of the benefits, however, will not be immediate, and many difficulties remain to be faced—not the least of them staffing Though the first Nigerian medical graduates from the University are now returning and will play an increasing part, the medical faculty, the consultants, and many of the residents and nurses must at first be drawn mainly from Britain—an arrangement facilitated by an agreement recently concluded with the Ministry of Health by which doctors, nurses, and technicians may accept engagements at Ibadan for periods not exceeding six years without losing their position under the National Health Service superannuation scheme

The hospital board of management has repeatedly expressed its lively appreciation of the practical help and interest of the University of London and other British universities and of the valuable contacts which have been established with individual medical schools and teaching hospitals The outstanding need is to secure a medical staff, consultant and non-consultant, of the right size, composition, and quality The opportunities which Ibadan offers for an interesting and rewarding medical career are manifold, and good progress has already been made in building up a suitable staff of resident medical officers and registrars Broadly speaking, the consultant medical staff are recruited and employed by the University College, though they hold honorary appointments under the hospital Important and interesting vacancies exist, or are impending, in this group

* * *

It is not the least of the results of the Royal visit to Nigeria that there is in Britain an increased consciousness, not only of our unity with her peoples, but also of the extraordinary progress which they are making towards their development as a self governing nation To this progress the new University College Hospital will make an important contribution in the years to come

Public Health

BACTERIAL RODENTICIDES AND INFECTION WITH *SALMONELLA ENTERITIDIS*

JOAN TAYLOR
B Sc, M B Lond, D P H
DIRECTOR, SALMONELLA REFERENCE LABORATORY, COLINDALE, LONDON

EVIDENCE is presented here that the jena and danysz varieties of *Salmonella enteritidis* are pathogenic to man and animals, and that disease in man and animals is sometimes caused by rodenticides consisting of living cultures of one or both of these organisms

Table I shows that both the jena and danysz varieties of *S enteritidis* cause sporadic cases and outbreaks of food poisoning, including some fatal cases in this country These findings support similar evidence from other European countries and from the U S A The use of *S enteritidis* for destroying rodents is unjustified because man has been accidentally infected in the past and may be so again An outbreak in Stoke on-Trent, due to the jena variety, caused 6 deaths in about 30 people affected 'Liverpool Virus' was suspected of being the source of infection, but complete proof was lacking

An outbreak in 1944, described by Dathan et al (1947), showed conclusively that infection of 4 children was due to the use of a "virus" preparation In this outbreak a child was seen handling an empty bottle of the "virus" preparation *S enteritidis* var *jena* was isolated from this bottle, from the child, and from 3 other children in the household

A large outbreak due to the danysz variety reported privately by Avent showed conclusively that human illness was caused by infection with this organism In an outbreak associated with vanilla slices only 2 persons were known to have had symptoms, and *S enteritidis* var *danysz* was isolated from the mice in the bakery concerned The bakery had been baited with *S enteritidis* var *danysz* to clear it of vermin a month earlier (Ministry of Health 1955)

Scott (1933) described an outbreak, affecting 38 people and causing 1 death, in which food was probably infected by mice A "virus" preparation containing *S enteritidis* had been used in the establishment, and this organism was isolated from apparently healthy mice on the premises These mice were probably infected by the "virus" and became healthy carriers

So far the emphasis has been placed on infection in this country, but there are many reports of outbreaks and deaths in other countries Leslie (1942) reviewed the published cases of human infection, due to the use of "virus" preparations, in Denmark, Germany, the U S A, and other countries

The use of bacterial rodenticides raises many problems The rodents, as a result of eating bait, develop gastroenteritis and, if it is fatal, die of septicæmia (Bahr 1947) During this illness the organisms are excreted in the fæces, which may infect food As in all salmonella infections, some of the rodents become infected and remain healthy or recover from the infection Branham and Robey (1929) showed that mice infected with *S enteritidis* may excrete the organism in the fæces for up to 21 days, Welch et al (1941) have shown that experimentally infected rats may excrete the organism in fæces for up to 148 days, and Price Jones (1927) showed that *S enteritidis* could be isolated from the organs of such apparently healthy animals, which initiated an outbreak when mixed with non infected stock It is obvious that these apparently healthy rodents may also infect food

During the acute septicæmia in rodents fleas feeding on them become infected (Eskey et al 1951) and may be a factor in spreading infection among other rodents Possibly fleas from the dead rodent may even bite and infect man, as in the spread of plague, but there is no evidence that this has ever happened

The bait used with these "virus" preparations is laid where there are runs, these may be where cockroaches abound Mackerras and Mackerras (1948) have shown that, in a hospital ward where there was an outbreak of salmonella infection, the cockroaches became infected Mackerras and Pope (1948) have shown that infected cockroaches may continue to excrete salmonella in the fæces for 14 days or more Cockroaches may also become infected from the "virus" baits and spread the salmonella This danger may be very real, as in the outbreak affecting 123 people, described by Spray (1926), who concluded that organisms were probably transferred by flies or ants from the rat "virus" to milk and cream This outbreak was due to *S enteritidis*, and tests seem to indicate that the organism was the danysz variety

Another way in which human infection has arisen was described by Lütje (cited by Hohn and Herrmann 1935) in an outbreak affecting 126 people The infection was traced to a pig infected with 'Ratinbazillen' which became ill, was slaughtered, and was passed as suitable for human consumption Table II shows that various animals may be infected with *S enteritidis* of either the jena or danysz varieties and so increase the chance of both human and animal infection

Kristensen (1946) surveyed *S enteritidis* var *danysz* infection in Denmark from 1926 to 1945 inclusive During

LONDON SATURDAY MAY 5 1956

Freud

Seldom has one man been so incontestably the creator of a new field of thought as **Freud** was of psycho-analysis Whether we accept it as a profound new science or doubt it as a far-fetched speculative system, we must wonder at the massive and daring product of one fertile original mind, working with intense concentration through more than forty years Now, a century after **Freud**'s birth there is still dispute about the value of his achievement, but hardly about the force of its impact on contemporary thought It can be said of him (as it was of another notable disturber of pleasant illusions concerned in part, with the sexual impulse) that he dug into the mine of truth bringing up ore mixed with dross to such purpose that he did not leave opinion where he found it his theory provided " a ground on which to fix the levers that may move the world "

Psycho-analysis is, of course not only a theory but also a therapy. It took its origin in efforts to cure hysteria, and almost all its medical expositors and investigators have been dependent on the practice of psychotherapy as a source of evidence and experience, and generally as a means of livelihood This has influenced the development of the subject, and its critical study Whether the effect has on the whole been for the good of psycho-analysis as a branch of medicine is hard to say No one has succeeded in amassing statistical evidence that it is more effective in the treatment of neurotic or other mental illness than other methods, though in the opinion of many people statistics has not the final say in this matter **Freud** himself saw some of the inherent obstacles to statistical evaluation—small numbers of patients, heterogeneity in form and severity of illness mutability of technique, premature termination of treatment—and he asserted that in any case the therapeutic aspect of psycho-analysis was not the most important

It is one of the many paradoxes in **Freud**'s career that he was deeply indebted to his medical training yet rejected it in retrospect ' I have never really been a doctor in the proper sense I became a doctor through being compelled to deviate from my original purpose, and the triumph of my life lies in my having after a long and roundabout journey, found my way back to my earliest path ' It is impossible to tell what he would have done if his training had been in philosophy or in psychology, as psychology was then. What seems clear is that his earliest researches, in neural structure, the action of cocaine aphasia and the paralyses of children confirmed him in habits of minute observation, organisation of diverse material deduction and lucid expression which served him well in the bolder studies that occupied his mature years In this matter he was unjust to his own achievement and his self-estimate erred on the romantic side ' I am not really a man of science, not an observer, not an experimenter and not a thinker I am nothing but by temperament a Conquistador—an adventurer if you want to translate the word—with the curiosity the boldness and the tenacity that belongs to that type of being His excursions into fields of human endeavour remote from clinical medicine derived from his overmastering desire to understand human nature Medicine gave him, in psychotherapy the springboard from it he plunged into literature, sculpture history, and anthropology, seeking always to find the ulterior meaning of men's conduct and the motives of creative action In these audacious forays cautious deduction which his teacher **Brücke** had once commended in him was a quality hard to find he took risks and made mistakes as any amateur must But these counted for little, when set against the stir he caused the incitement to fresh inquiry the lively light cast into dull-seeming corners and neglected depths Our ideas about education, religion crime, and many other human concerns have been shaken about by the impact of this restless, penetrating subtle mind. Techniques of which **Freud** had no inkling or for which he would have no sympathy are now being deployed to test the validity of his theories and suggestions not only in dynamic psychology and psychiatry, but in the social sciences at large

It is appropriate that **Freud**'s centenary should be commemorated with especial regard in this country, for it was here that **Freud** came as a young man (on a journey that he said had a decisive influence on his whole life), here that he thought of settling and here that he found refuge when driven from Vienna by the Nazi occupation He probably owed some pregnant ideas to 19th-century English thinkers—notably **John Stuart Mill** and **Hughlings Jackson**—and he found in an English disciple his faithful and gifted biographer. Though his work transcended frontiers and was accepted in some other countries particularly the United States, more readily and eagerly nowhere more than here can there be respect for the courage and intellectual integrity which led **Freud** along strange paths, on a noble and endless quest

Methionine and Hepatic Cirrhosis

The mental disturbances that may be associated with hepatic cirrhosis include clouding of consciousness confusion, apathy personality changes abnormalities in behaviour, and finally, delirium and coma [1] Signs may appear in the motor system such as spasticity, increased limb reflexes involuntary movements, and a peculiar flapping tremor [2] consisting of a series of rapid flexion-extension movements at the wrist and metacarpophalangeal joints best demonstrated with the arms outstretched and fingers separated It is important to appreciate the diffuse nature of the cerebral disturbances and their connection with liver disease since, as **Sherlock** and her colleagues have pointed out,[3] the patient may all too easily be admitted to a mental hospital before the true diagnosis is reached

These complications arise in patients with hepatic cirrhosis who have large collateral channels between the portal and systemic venous systems, and they

*Six colonies from a single bait

Inquiries at the butcher's shop and at the slaughterhouse did not throw any light on the case, and the means by which the organism got into the food and what component of the food was responsible, has not been elucidated

The organism concerned was of the danysz type, used in certain rat poisons, but inquiries failed to establish that such poison had been used anywhere near the food

From the explosive and widespread nature of the outbreak it seems probable that the food—most likely the meat used for the "savoury mince"—was somehow heavily infected before reaching the depot Both in the refrigerator and in the oven the centre of the mass of mince probably did not reach a temperature sufficiently low or high to inhibit the growth of the organism, which therefore multiplied all the time (24 hours)

The standard of hygiene at the depot is very good, and I am satisfied that no blame can be attached to the staff for this occurrence

The incident is an example of the increased risk of such outbreaks under present conditions, with large numbers of people depending on communal feeding arrangements, and the necessity for all possible care on the part of those handling food at any stage

Outbreak Due to S enteritidis *var* jena

This outbreak was reported in *The Lancet* (1945) At Stoke on Trent a small lock up cook shop, supplying meat sandwiches, meat, potato pies, and cooked dinners off the premises, carried on in addition a small grocery business The premises were infested by mice, and the occupier had been in the habit of using Liverpool Virus An outbreak of food-poisoning occurred in relation to food sold in this shop, affecting more than 30 patients, of whom 6 died From the patients investigated *S enteritidis* var *jena* was isolated Food taken from the premises was examined, but no salmonella was isolated *S enteritidis* var *jena* was isolated from a partially consumed sandwich found in the pocket of one of the patients The Liverpool Virus used on the premises was not available for examination A sample of this preparation was obtained and proved to be a pure culture of *S enteritidis* var *danysz* Samples of Liverpool Virus had been examined in 1944 and found to contain the jena variety (table III), and possibly the preparation used in the shop was of the same type

Animal Infections

Both the jena and the danysz varieties may affect animals, as shown in table II

Rodent Virus Preparations

From 1944 onwards various preparations have been investigated to determine the species and variety of salmonella organisms present In some instances the "virus" preparation was examined in this laboratory, in others the "virus" preparation or a "virus" infected bait was examined elsewhere, and a single colony culture sent for examination For this reason the data are presented under two headings in table III, which shows that, certainly as late as 1949, both the jena and the danysz varieties were used in "virus" preparations Since that time only the danysz variety has been isolated from material or cultures of material received here

In 1945 it was possible for anybody to buy "virus" preparations from retail shops, but this is now impossible "Virus" preparations are still used by the representatives of some firms undertaking pest control At present anyone may buy Institut Pasteur "virus" by writing to the Pasteur Institute, payment being made on an international reply coupon

Although the only salmonella found in "virus" preparations in recent years has been *S enteritidis* var *danysz*, there appears to be no official control of the varieties of organisms employed It has been shown that the jena variety was in use until 1949, and Bainbridge (1909) refers to the use of *S typhimurium*

The data show that the jena and danysz varieties of *S enteritidis* are pathogenic to both man and animals Some of these infections have been traced to the use of bacterial rodenticides both at home and abroad

There are other more effective methods in use for the destruction of rats and mice The Ministry of Food (1946) recommends certain methods of control but doe not include bacterial cultures Bainbridge (1909) reported a death rate of 20-50% from bacterial cultures It is believed that chemical poisons give a higher death rate, and their use is recommended by the Ministry of Agriculture and Fisheries Moreover, the chain of spread of salmonella infection, which may be through man animals, and insects, does not exist in the case of chemical poisons

A Working Party, of which Prof S Zuckerman was chairman, set up by the Ministers concerned to advise on precautionary measures against toxic chemicals used in patients with coexisting cerebral arteriosclerosis[14], but it should also be borne in mind with less severe attacks in younger individuals[15] Experimental[16] and clinical[17] pathologists have been able to demonstrate organic cerebral damage, and psychiatrists have detected mental deterioration, using intelligence tests and electro encephalography,[18] after repeated hypoglycæmic episodes This is certainly a danger to be weighed against the advantages that can be attributed to long-term strict diabetic control, which for this reason should not be expected to attain chemical standards of normality[19] SOMOGYI attributes[20] some of the wide and seemingly spontaneous swings in blood sugar in so-called "brittle" diabetics to the hyperglycæmic reactions to episodes of hypoglycæmia and to the tendency to treat these hyperglycæmic peaks with more insulin The increasing reliance on single daily injections of long-acting insulins has increased the risk of hypoglycæmia not only because errors of overdosage are concentrated into single injections, but because the blood-sugar is often at its lowest during sleep (especially with protamine zinc insulin), when prompt treatment is unlikely For this reason it is probably unwise to give insulin in single long-acting injections to a patient who needs large doses, especially if his insulin needs are known to be variable And this is also why patients on long-acting insulins are advised to take bedtime snacks containing a proportion of protein to sustain the blood sugar longer than would be possible with isocaloric amounts of carbohydrate

When hypoglycæmic attacks occur in hospital confirmatory evidence is often sought from the blood-sugar, and not uncommonly this is found to be unexpectedly high,[21] thus casting doubt on the assumption that hypoglycæmia was the cause of the symptoms The situation is complicated because, by the time the blood is withdrawn the patient may be in the phase of rebound hyperglycæmia attributed to adrenaline-induced glycogenolysis Indeed many of the classical symptoms of hypoglycæmia may be traced to adrenaline, for diabetics taking ganglion-blocking methonium compounds may slip into hypoglycæmic coma without such warning manifestations[22] Vasoconstriction due to the release of catechol amines may serve to intensify hypoglycæmic symptoms by adding an element of anoxia to a perhaps already impaired cerebral circulation Thus vasodilator drugs have been shown to improve hypoglycæmic manifestations when given without sugar[23] If the blood-sugar level is falling very rapidly then the brain may be shorter of glucose than is suggested by a blood-sugar which seems relatively normal[24] JOSLIN[25] was one of the first to draw a parallel between the effects of hypoglycæmia and those of anoxia Different parts of the brain are involved in the same sequence, and both processes have the same end-result of reducing cerebral metabolic activity, since glucose, even in the untreated diabetic, is the only fuel burned by the brain Thus it is that chronic mild cerebral anoxia may promote the development of clinically apparent hypoglycæmia, just as coronary atheroma may give rise to typical anginal pain during mild hypoglycæmia[26] JONES[13] has described as 'hypoglycæmic encephalopathy' the cerebral damage following hypoglycæmic attacks thereafter the brain may be more liable to similar attacks even at higher blood-sugar levels[21] The surest confirmation that an attack is hypoglycæmic lies in its response to intravenous glucose

THE WELFARE OF SPASTICS

THE organisation of a national scheme for the welfare of children and others suffering from cerebral palsy was curiously neglected in this country until after the second world war In 1946 at a meeting in the London School of Hygiene and Tropical Medicine, the British Council for the Welfare of Spastics was formed with a broad basis of representation from medical, educational and other professional interests The aims of the council were to act as a central advisory and coordinating body for all activities directed to the well being of spastics, to assist in the early ascertainment and classification of spastics and in establishing schools and clinics, to promote research, and to help the parents of spastics by publishing informative books and pamphlets As time went on, the council established useful contacts with voluntary bodies abroad, especially in Australia and the United States, and they cooperated successfully with the Ministries of Education and Health in plans for training staff in the best known methods of education and social welfare The council's initiative helped in the establishment of residential and day schools, and they were closely concerned with the setting up of regional and local parents' associations In this and many other ways they broke new ground, but lack of funds and a certain reluctance, not uncommon in professional bodies to engage in widespread appeals to parents and the public made progress rather slow and formal.

The parents of spastic children, however, once their imagination had been fired, were in a hurry They were not content to jog along under professional guidance, they were determined to take the wheel themselves In this ever growing enthusiasm a number of parents, spastics, and their friends began to press for an immediate improvement of the conditions under which children suffering from cerebral palsy were receiving education, medical care, and the special forms of speech training and physiotherapy which have proved so valuable The National Spastics Society was formed in 1952 and immediately began to form parents' associations on a nation wide scale The brilliant publicity campaign organised by the central body through the press, the wireless, and the theatre still further stimulated the enthusiasm of parents and the formation of local associations, and large sums of money were collected by house-to-house visitation The National Spastics Society have in fact scored a resounding success, and honour is due to them for their courage and resourcefulness

Nevertheless, the situation has its own embarrassments in the process of the campaign the essential problems of the spastic have been oversimplified, and

The Widdicombe File

XXXIII. ON A PERSONAL NOTE

MY DEAR WHIDDON,

Things are coming to a pretty pass indeed! Your precious Management Group Secretary has the nerve to claim that every letter I write to you about a patient automatically becomes the property of his hospital. It does not seem to matter even if I mark it "Private and Confidential": it is filed with the hospital records just the same. Damned presumptuous, I call it.

On the contrary, persists the Group Secretary, every general practitioner who writes a letter to a hospital consultant knows what is customarily done, and thus he implies consent for his letter to be included in the records. Stuff and nonsense, I retort; not one general practitioner in a thousand bothers to think about the consequences of writing friendly notes to help his professional brethren or his patients. More fool them, shrugged the Secretary. And that is where you come in, *my dear Whiddon, for it cuts both ways.*

If it is worth writing a letter at all, it takes two people to make it a success. Unless there is implicit confidence between us, the text of the letter and its sincerity will not be worth the paper it is written on, never mind the 2½*d.* stamp. None of us in our right senses are going to put down all that is in our hearts if we suspect that the fellow at the other end is allowing a bunch of strangers to peep over his shoulder. Still less are we going to be happy about the risk of our letters being bandied about by all and sundry, some of whom may be bloody-minded towards us in these compensation-worship days. Such suspicions gnaw at the very basis of the traditional confidence which ought still to exist when one doctor writes to another about a patient.

They tell me that in theory the copyright of a letter remains with its author; and, though I don't suppose many general practitioners make a habit of endorsing their letters to you "All Copyright Reserved," this could be a point worth remembering. It might prove helpful in these days when hospital records are lent to Government departments, and, on strange occasions, may even fall into the hands of the patients themselves and their legal advisers.

If we were to take a firm stand on copyright, might it not become obligatory to ask each writer for his consent before publishing his letter to any other party? That would shake the Group Secretary's office! At present they get away with their self-chosen practice of asking the consultant in charge of the case to review the records and say whether the notes can be borrowed by the laity. Now, my dear fellow, I would trust you with all my heart to do that; but I can think of one or two of your colleagues who might not be quite so acceptable, human nature being what it is. I certainly would not approve of the hospital nominating an official scrutineer for the purpose. Confidence has a personal quality, like a delicate flower to be cultivated and tended.

Delicate flowers remind me of my old Uncle George. Do you remember meeting him at the Chelsea Show before the war? He was not only an expert on orchids, he was a damned good lawyer as well. I always remember him holding forth on the subject of qualified privilege in correspondence. He used to say that a qualified privilege existed when the person who makes a communication has an interest or a duty—legal, social, or moral—to make it to the person to whom it is made, and that the person to whom it is made has a corresponding interest or duty to receive it. I think that you and I easily satisfy those conditions when I write to you about Mrs Popplecorn. Whether I have a legal duty to do so under the mass of N.H.S. legislation I would not know without rummaging out my desk; I am sure that I must have a social duty in this age of social medicine. I certainly have a moral duty not to spin you half a tale.

But old Uncle George was careful to point out that our qualified privilege will be lost if the communication was actuated by malice. Goodness knows, there has been a wealth of gentle malice in some of my notes to you. Mrs Popplecorn suffered far less pain in her neck than I did when I attended her. Old Colonel Firebrace was a left-handed gift to your consulting room. Was it really malice on my part to betray their hideous characters, or was it my compassion to spare you ferreting out the truth for yourself? Perhaps we need bother no more about those finer ethical points, for Uncle George showed us that we could rebut the presumption of malice by proving that the publication to another party was made without the writer's authority or knowledge. Uncle George has been pushing up the daisies for a long time now, and maybe the law has changed since then; but all the same I think he has left us a few good tips.

When I look back I can think of some notes to you that would not have done me much good in a court of law. Do you remember the odd mistakes of my early days which I sent along to you to put right? Just fancy what would have happened if one of those got back to the patient! Somehow I feel it was better to have owned up to you about them than to subscribe to this present-day creed of writing notes for the main purpose of squaring one's own yardarm, or, in the less polite language of the Civil Service, of keeping one's nose clean. I can see that you consultants are having the same difficulties with your letters to us. Your phraseology is becoming tainted with a brand of dour caution inspired by the shadow of the Legal Aid Fund. Not only is there a danger of losing confidence between consultants and general practitioners, there is also a danger of losing the more civilised techniques of self-expression.

What, Whiddon, do you think we ought to do to protect and restore that confidence? What can we do to preserve intact the free and full exchange of information and opinion between doctors? Can we beat the enemy at their own game? I suppose that the endorsement "Private and Confidential" carries no special significance, for are not most medical documents contemptuously so marked? "Copyright Reserved" is perhaps rather too pedantic. I have a theory that a simple endorsement "Personal" might suffice to rescue my confidences from the clutches of the lay administrators; but of course you will have to put up with having your jacket pockets bulging with papers unless you adopt some memory-man technique and swallow the notes like a first-class spy.

Another bright idea might be to copy the lawyers' device of endorsing their more scurrilous communications "Without Prejudice"; and what they get away with under that umbrella is just nobody's business, not even the court's. A system of dual letters in parallel, one stating the truth for your private eye, and the other providing eyewash for the hospital records, seems a little too schizophrenic, and fraught with the horrible possibilities of intermixture under stress in the witness-box. It would be simpler to devise a secret code if we were not so involved with security scares over atomics and space satellites.

I don't know just what the answer is, but it will be a sorry day when you and I have to write to each other about Mrs Popplecorn on notepaper which carries on the reverse side a schedule in small type setting out the conditions of communication between us. It may give some gratification to the administrators to see us using the appropriate form. But one person at least is likely to lose rather than gain—and that person, as I need hardly say, is our Mrs Popplecorn.

Still very hot under the collar,

Yours sincerely,

WILL COBBLEIGH

gained favour, ousting plombage and largely replacing thoracoplasty

The present position of plombage has been reviewed by Jackson and McCann[8] Although in their series of 203 operations in 191 patients, infection was relatively uncommon compared with some other reported series, they nevertheless conclude that the problem of preventing such infection remains unsolved and that the trend of surgery in pulmonary tuberculosis is towards removal of the tuberculous focus rather than its collapse They still advocate plombage in certain circumstances (for example, for patients in whom resection is considered unwise and thoracoplasty dangerous, and for those with bilateral disease where the conservation of the greatest possible respiratory function is essential) It is also of value at times in thoracoplasty, the plomb being removed at the second stage Time will tell whether long-term chemotherapy is not a better line of treatment in patients who are doubtful surgical risks, but the indications even for resection appear to be contracting, for plombage, many think, they have already disappeared, particularly since modified one stage thoracoplasty[9-11] is being perfected, which offers most of the advantages of plombage without its dangers

PROGNOSIS IN ADDISON'S DISEASE

Few therapeutic advances in recent years have been more impressive than the development of endocrine therapy in Addison's disease A condition which was almost inevitably fatal a quarter of a century ago now promises to be compatible with a normal lifespan[12] As Dunlop[13] pointed out, there have been four eras in the treatment of this disease In the first era (1849–1930) there was no really effective treatment The average length of survival in tuberculous cases was only just over a year from the onset of symptoms, in simple atrophy it was just under three years Only a few patients survived for a number of years—the longest recorded survival being eighteen years[14]—and one or two recovered partially or even completely[15 16] The second era opened with the introduction of Swingle and Pfiffner's cortical extract[17 18] This produced immediate benefit but the long-term results showed little improvement, 23 of Dunlop's 30 patients still died within one year of diagnosis Using Swingle's extract continuously, with a high intake of salt, Rowntree[14 19] was able to keep 5 out of 8 patients alive and well for an average of ten years from the onset of symptoms, and 4 were still alive in 1955, having survived an average of nearly seventeen years 2 of these 4 patients had received additional deoxycortone acetate for four and ten years respectively, and the other 2 had had small doses of cortisone during the past three years[15]

The third era extended from the introduction of deoxycortone in 1938[20 21] to the use of cortisone in 1950 Thorn[22] reported that 48% of a group of 158 patients survived for an average of ten years under treatment with deoxycortone—supplemented from time to time with whole adrenal extract—whereas before 1930 50% had succumbed within one year Many of the patients were maintained in good general health with regular implantations of deoxycortone pellets, and the use of cortical extract during crises, but they remained unduly susceptible to infections, many of which proved fatal

The fourth therapeutic era opened with the introduction of cortisone as a regular medication, and of intravenous hydrocortisone in crises This so much improved the prognosis that Thorn et al think that "at present the well supervised patient with Addison's disease should have a nearly normal lifespan"[12] Good supervision, in their view, involves imposing on patients conditions similar to those commonly applied to diabetics Not only should they receive regular cortisone and deoxycortone, but they should carry emergency supplies of cortisone acetate tablets and suspension, deoxycortone in oil, and sodium chloride capsules. Thorn et al also recommend that each patient should carry a card giving (a) the diagnosis, (b) the name, address, and telephone number of his doctor and next-of-kin, and (c) instructions to give the patient 25 mg. cortisone acetate by mouth—or 100 mg intramuscularly —if found collapsed, and to notify his doctor immediately Patients should also be instructed to take an extra 50–100 mg cortisone daily in the presence of infection, and likewise to notify their doctor A supply of a broad-spectrum antibiotic might well be added to this "iron ration" of cortisone and deoxycortone which Thorn et al recommend

Only by regular supervision, and by education of the patients and the profession along these lines, will unnecessary deaths be avoided and patients given the best chance of a full lifespan

EXTRADURAL HÆMATOMA

The mortality of traumatic extradural hæmorrhage is high Spurling[23] put it at from 30 to 50% in large centres in the United States Schneider and Tytus,[24] of Ann Arbor, have recently analysed some of the factors in the high death-rate, and Lewin,[25] in a Hunterian lecture some years ago, studied the problem in detail The classical clinical development of middle meningeal hæmorrhage and the need for operation have been recognised since the descriptions of Percivall Pott,[26] Jacobson,[27] and Hutchinson,[28] but by no means all patients present the typical picture Lewin analysed 34 cases admitted between 1940 and 1949 to the Radcliffe Infirmary and the Military Hospital for Head Injuries, and in 20 the illness conformed to the classical description, with minor variations The head injury may be slight without loss of consciousness (as in 7 of Lewin's cases) and it is often a blow on the temple, but sometimes (in 9 patients in this series) the head injury is severe and there is no lucid interval of recovered consciousness before cerebral compression develops In this group diagnosis may be difficult, since the signs of cerebral compression appear on a background of cerebral contusion Considerable importance is usually given, in the diagnosis of extradural hæmorrhage, to dilatation of the ipsilateral pupil, later followed by changes in the opposite pupil, but in nearly half Lewin's patients there were no abnormal ocular signs, and they should be regarded as a late and inconstant feature of the condition A unilaterally dilated and inactive pupil following a head injury may be due to traumatic mydriasis or injury of the oculomotor nerve, but in these conditions the pupillary abnormality will be present from the time of the injury When the pupil dilates as the result of

Letters to the Editor

REVISION OF THE CURRICULUM

SIR,—Professor Wyburn's letter last week is profoundly disappointing As an advocate of radical reform of the curriculum he must surely know that such reform is impossible anywhere in this country except on the instructions of the General Medical Council, or by its permission Both because the G M C is a conservative body and because it has liberal traditions, we can rule out the possibility of radical reform being undertaken on its instructions it is never going to adopt an "experimental" curriculum and impose it on all medical schools Hence the only hope of getting anything done, after so many years of talk, is to persuade the G M C that it can safely allow teaching authorities liberty to experiment for themselves To say that the council is being asked to "abrogate its function as guide and supervisor of the training of medical students" is untrue it is being asked to exercise this function in a different way, relying on advice to individual schools rather than on general directions to all

This approach should surely have the support of all who want alterations of any kind whether (like the Royal College of Physicians) they favour a basic medical education or (like Professor Wyburn) they prefer a more vocational and utilitarian training For they will get neither unless the council accedes to the college's request

If it does so, and if major reform of the curriculum becomes at last a practical possibility, it will then be important to decide in each medical school whether and how far the teachers can agree on general educational objectives Professor Wyburn may then be able to carry the day in his own school, without having to enforce his views throughout the country This would be greatly to the satisfaction of those, such as myself, who are not so convinced as he that there is only a single remedy I do not believe that a curriculum is ever likely to be perfect in concept or application in any school, and I therefore am wholly in favour of the "interminable 'research'" that he condemns He may be correct that the training for lawyers is not so subjected, but the law does not change so rapidly as medicine On the other hand, if true, it is distressing to hear that the trainings for engineers and for scientists are not regarded as being in need of constant review aimed at improvement I do not personally consider that our knowledge of learning processes or our application of it justifies such complacency

It is, of course, entirely untrue to state that the curriculum is not considered by those whom Professor Wyburn describes as "best suited to advise"—the general practitioners Clearly he has not seen fit to study the published opinions of the College of General Practitioners This is extremely unfortunate, for had he done so he would have discovered that not all who are actually engaged in this branch of medicine regard themselves as merely skilled technicians Nor do they all favour a purely utilitarian training—irrespective of the fact that were it to be adopted for all, some 50% of students (who do not later enter general practice) would thereby be given a curriculum much of which might, as Professor Wyburn claims is the case at present, be "wholly irrelevant to the work subsequently undertaken"

Furthermore it appears to me that many general practitioners do not find "the job" easy to define dogmatically, but are convinced that what the people need is a doctor who is not only conversant with the common knowledge and proficient in the common techniques that are current at the time of his registration, but is also capable of learning new knowledge and new skills (It must be admitted that the general practitioner is at least as well placed as a professor of anatomy to know what "the people want") Perhaps Professor Wyburn's own single positive contribution—that the education of the medical student should "include, from an early stage, a concurrent and remunerated apprenticeship"—is intended to achieve this aim, but as it stands it is no more than a bare "pronouncement," and does not even make it clear whether the remuneration should be *additional to the present system* of grants and subsidies

The Royal College of Physicians was asked to amplify its original memorandum,[1] and it has done so It has reiterated its request that the G M C should abandon control by prescription *in order to foster experiment*, and Professor Wyburn is entirely wrong in suggesting that the college has done this in order to impose a "model curriculum" of its own upon anyone

To me he seems equally wrong in suggesting that the college has nothing else positive to add to the pronouncements so often made in the past He may note that, in describing the kind of framework within which it thinks the schools should design their own curriculum, it says that preclinical studies should not start till 18, and that exemption from the 1st M B should be obtainable by students taking only two scientific (and one non scientific) subject at advanced level in the G C E In discussing the implications of a basic medical education, it points out that any school which wants to integrate preclinical and clinical studies will have to be prepared to alter the 2nd M B, and it asks the council to refrain from issuing any general instructions on the content or timing of examinations, because this "might prevent the development of a method of progressive assessment which could be an alternative to the present examination system" There are *many* in the profession who share the college's belief that "at all stages of medical education, examinations now exercise an unhealthy dominance over the students' work and thought" Do they realise that nothing can be done about this dominance until a progressive medical school has been allowed to demonstrate that equally good (or better) doctors can be produced on some different system ?

The college is asking that if the teachers of any school believe they can improve their course—and can agree on how to do it—they shall have freedom to try Does Professor Wyburn really want to dissuade the General Medical Council from taking what has been rightly called the "essential first step towards reform"?

London Hospital, E 1 JOHN R ELLIS

SIR,—The letter by Professor Wyburn will be widely read with gratitude for its authoritative and robust common sense How refreshing to read that crucial statement "the people want a doctor who knows his job" So many of our academic medical ornaments seem to discover the truth of the statement only when they, or their families, fall ill Again, the manifestly true, but politically most dangerous, conclusion that "the present training of the medical student is unsatisfactory, uneconomic, and much of it wholly irrelevant to the work subsequently undertaken by the great proportion of medical graduates" leads one to fascinating musing on the theme what happens if public money voted for one object is used for another—however desirable in itself and even if this object be removed from critical appraisement by the inhibitory label "research"

Again, medicine is "not a science" but "a skill, much of it still empirical" and the inevitable conclusion, clearly stated—"apprenticeship" Great is the truth —may it prevail

HE PATTERN OF GENERAL PRACTICE

A G RICHARDS
B.A., M.B Camb
ASSISTANT PHYSICIAN,
SASKATOON SANATORIUM, SASKATCHEWAN, CANADA

MOST doctors visiting Britain from Canada and elsewhere have kind words for British consultant and specialist practice, but usually they are not so favourably impressed by general practice, of which Collings (1950) made a detailed and critical survey This unfavourable impression is created partly by conditions which individual practitioners could rectify, and by certain provisions of the National Health Service Act But the pattern of general practice is largely determined by factors not easily modified by doctors or legislators—e g, density of population ease of communications, capital resources, and the prosperity of the community Whereas specialist practice is basically the same the world over, general practice must adapt itself to local circumstances

To be constructive criticism should be directed against conditions of general practice that can be modified, and against failure to adapt to those conditions that must be accepted. To set before future general practitioners an ideal type of practice which is unattainable is unfair and also a disservice to their patients

Existing Patterns

A much-criticised aspect of British general practice is the limitation of scope in the treatment of organic disease particularly that imposed by lack of hospital privileges

In the country districts of Canada and the United States, most communities provide general practitioners with X-ray equipment, electrocardiographs, and hospitals which in Britain and Europe would be confined to large cities Furthermore, owing to the dispersal of the population in such large countries many general practitioners work far away from medical centres and specialist help, and they must deal with all surgical and medical emergencies But even in the cities the ideal of the self sufficient practice is pursued Since specialists in North American cities usually do not confine their practice to referred cases they are in direct competition with general practitioners who therefore, even more than their British colleagues feel a need for the prestige value of equipment and hospital privileges

In Britain a much lower proportion of the country s capital resources is devoted to general practice and to hospitals than in Canada and the United States Premises suitable for general practitioners, and even general practitioners themselves are scarce in some areas. Because of the shortage of hospital beds the British general practitioner spends much time visiting and treating patients in their own homes much of his visiting is in effect a vast ward round Because of the shortage of practices these are large—there is an average of over 2000 patients per doctor (Hadfield 1953)—and in cities they tend to be very large Shortage of hospital beds and the large size of his practice combine to fill the general practitioner's day with work outside the hospital

Nevertheless, because Britain is densely populated a reasonable standard of medical care is possible despite these shortages, for frequent visiting is feasible, and patients need not be admitted to hospital merely because they live too far away for supervision, as is often the case in Canada Furthermore in Britain visiting is eased by the good roads, universally tarred or "paved." Specialists are within easy reach, and the amount of major therapy which a general practitioner is justified in undertaking is therefore greatly reduced

The Canadian doctor, except in the largest cities, minimises the distances he travels by having his house and office within easy reach of the hospital, by commonly advising his patients by telephone and by visiting patients in their homes only when he must His practice is therefore limited only by the distance patients travel to see him, which may be 40 miles or more In Britain, because home visits constitute such a large part of his work the general practitioner must restrict his practice to a convenient area A hospital serves an area containing many practices of which only a few will be near to it A doctor whose time is filled by travelling about his practice may find it difficult to fit in a long journey to see a patient in hospital This was my experience in a semi-rural practice in Lincolnshire a small hospital was available to some 10 general practitioners, but in fact only 4 of us whose practices included the hospital geographically used it to any extent

THE HOSPITAL

It was my experience in Britain that the patients for whom I was responsible in our small general-practitioner hospital would have benefited from the care of a doctor who, if not a specialist at least spent most of his time doing hospital work and I had a suspicion that my patients would have been more efficiently managed in the fully equipped hospital with resident staff 16 miles away. Doctors in large practices with several partners can afford the time for regular hospital work but the single practitioner or member of a small partnership finds that his few hospital patients cost him a disproportionate amount of time, effort and worry A doctor who does most of his work in hospital is not bothered by the feeling that he should be elsewhere, but the practitioner attached to a hospital is always having to consider conflicting priorities and an emergency in hospital may coincide with one outside Hospital work requires not only skill in certain procedures and experience in interpreting special investigations but the establishment of harmonious personal relations with all members of the staff A hospital is an instrument, and as with other instruments, a certain critical frequency of use is needed to maintain proficiency The doctor who combines hospital work with a busy general practice is continually having to make the effort to change his mental orientation to a different pattern of work This adds to his burden and impairs his efficiency

An objection to the reservation of hospitals for specialists is that patients lose the continuity of care and personal interest of their family doctor but the wise patient prefers to be operated on by an experienced surgeon even if he is a stranger A further objection is that doctors lose sight of their most interesting cases through admission to hospital But why do doctors think these cases so interesting? Surely because they are cases of disorders about which they were taught as students in hospital, whereas the majority of patients seen in general practice are not The late Sir James Spence drew attention to the large number of illnesses seldom dealt with in hospital teaching (Spence et al. 1954)

This division of labour between hospital practitioners on the one hand and non-hospital practitioners on the other makes for effective use of doctors in densely populated areas Unhappily because of our undergraduate training we find it hard to accept this situation and make the best of it There is a risk that general practice may be forced into a form to suit our training instead of our modifying it in the best interests of patients and the profession.

General practitioners usually attribute the small number of hospital beds available to them to arbitrary regulations or selfishness on the part of specialists rather than to an inherent feature of British medical practice Many doctors feel that their prestige is impaired by lack basic method of treatment It has the advantages of precision and the immediate correction of possible diagnostic errors, and it preserves that sense of urgency in treatment on which early admission to hospital depends Conservative therapy has been used in those mild cases diagnosed as "leaking ulcers," and in others where the early diagnosis has been in doubt Some of these have been acute exacerbations of peptic ulceration or of antral gastritis, without perforation

Primary partial gastrectomy has been preserved for perforation in chronic ulcers in selected patients whose general condition has remained good and in whom diffuse peritoneal soiling has been absent, but the ultimate decision to proceed with this operation may have to be abandoned when the ulcer is exposed if conditions are unfavourable The plea is, therefore, for an accurate assessment of each case and the adoption of the procedure calculated to give the best results in the experience of the surgeon concerned

The claim that conservative therapy in perforated acute ulcers protects against relapses is one which only time can confirm, but it seems contrary to the nature of the disease

Newcastle upon Tyne JOHN GILMOUR

INFLATABLE POSTNASAL TAMPON

SIR,—Mr Mawson describes (April 21) an inflatable postnasal tampon There are two points in which this apparatus might be improved

For many years I have used a fine metal tube, over which is tied a large-size rubber finger-stall, this can be inserted into the nose and inflated to control hæmorrhage A spring-loaded valve, similar to a motor tyre valve, is incorporated in the proximal end of the fine tube and housed in a small light aluminium cylinder measuring 1 in by $^1/_4$ in This is, of course, self-closing after each puff of air is introduced and avoids the necessity of closing a piece of rubber tubing with a cross-action spring clip, or with a rubber cap, and is much more comfortable to wear

The second point is that if a double bulb is used for inflation similar to that employed for inflation of a cuff on an endotracheal tube, the pressure in the balloon or finger-stall can be more easily gauged This apparatus may be obtained from Messrs A L Hawkins, of New Cavendish Street, London, W 1

Royal Free Hospital,
London, W C 1 W G SCOTT BROWN

RESTRICTION OF ANTIBIOTICS

SIR,—I was very surprised by the opinion expressed in your annotation (March 3)

In point of fact, restriction on commercial distribution of an antibiotic seems to me detrimental to the public health The object of pharmaceutical firms is to supply the physician with new medicines, and *it is up to these* to choose the antibiotic best suited to each particular case The clinical and, more specially, the laboratory data (antibiograms) supply precise information Consequently, it appears to me that the more antibiotics a doctor has at his disposal, the easier it is for him to apply rational and effective treatment

If we adopt the course you favour, on what basis, and when, can a new antibiotic be placed at the physician's disposal ?

You mention an antibiotic on sale in France with, you say, *insufficient reason* Spiramycin (it is obviously to this antibiotic that you allude) has effective antibacterial properties rather similar to those of erythromycin, but clinical and laboratory data have shown that the similarity is not complete

I studied 50 different pathogenic staphylococcal strains, of which 42 were equally sensitive to each of the two antibiotics, 6 were resistant to erythromycin and sensitive to spiramycin, and 2 were sensitive to erythromycin and resistant to spiramycin Similar studies by other workers confirmed this, and it seems that 10% of staphylococcal strains are sensitive to spiramycin and resistant to erythromycin This discrepancy was borne out clinically, and there is evidence of success with spiramycin after failure with erythromycin

In our experience, spiramycin is better tolerated both digestively and generally at a daily dose of 3 g than erythromycin at 2 g daily This advantage was pointed out also by Sureau et al[1] who compared the results of treating scarlet fever by spiramycin and erythromycin

This justifies my point of view and the therapeutic interest in this new antibiotic *In combating infectious* diseases, each new weapon must be well known by the practitioner and placed at his disposal for his discerning use And obviously a patient infected with an erythromycin-resistant and spiramycin-sensitive organism (which from French observations will be once in about every ten cases of staphylococcal infection) would be extremely glad to benefit by this effective and well tolerated medicine

Tassin La Demi Lune
Rhône France J PELLERAT

*** As we see it, hospitals are experiencing an epidemic of antibiotic-resistant staphylococcal infection, which may spread to the general population In the face of such a threat to the public health we do not think that the policy of laissez-faire advocated by Dr Pellerat will be indefinitely acceptable either to peoples or to their governments Our plea is that the medical profession and the pharmaceutical firms should cooperate voluntarily *in measures to discourage the emergence of resistant* strains —ED L

HORMONAL EFFECTS OF TRANQUILLISERS

SIR,—The interesting letters of Dr Sulman and Dr Winnik and of Dr Marshall and Dr Lieberman (Jan 21) accorded with certain of our own observations During the past month, while examining a Papanicolaou smear obtained from the cervix uteri of a 68 year old patient who had had some recent bleeding episodes, we were amazed to find cornification of vaginal epithelium to a degree which suggested that the patient was receiving œstrogen therapy That, we were assured by her doctor, was not the case The patient had for some months been receiving only rauwolfia alkaloids, and it turned out that the bleeding coincided with the exhibition of *this medication*

In an investigation by one of us (R D B) of the tranquilliser, meprobamate ('Miltown,' 'Equanil'), in patients with inoperable neoplastic disease,[2] a patient with mediastinal and cervical Hodgkin's lymphadenopathy, previously responsive to hydrocortisone and to oxytetracycline in successive courses, but now refractory to both, showed progressive detumescence of the enlarged nodes in the first three weeks of sustained administration of miltown (400 mg by rectal suppository four times daily) administered for the control of anxiety This response was reminiscent in all respects of prior responses to adrenocorticotherapy or mycin antibiotics—in the case of one of which (chlortetracycline) humoral action *has been confirmed*[3] *It may be recalled that an* "adrenocorticomimetic effect" of this class of antibiotics has often been suggested to explain certain effects in diseases which are not *classically* "infective"

Experience with meprobamate indicates that the humoral effects of tranquillisers may not be confined to an anti-histamine or parasympatholytic one, as with chlorpromazine Nor is it certain that such effects do not noted wherever possible. The study was therefore likely to reveal, among other maladjustment, any examples of the "affectionless character" which is said to result from early separation.

Four Groups

The Well-adjusted

Of the 25 children, 8 were normal and generally well adjusted in their school life, while at home they were (if one can put it that way) better than normal. They were very affectionate and thoughtful towards their mothers, so much so that they helped in the home without being asked. 3 were eminently stable, but they had not been separated from their mothers until they were 3–4 years old, and for less than a year. All these 8 children had mothers who cared for them, although the mother of one of the girls was rather a cold type of woman who had never kissed or cuddled her children.

One is bound to ask—when one has had experience of completely secure and stable children—whether this helpfulness in the home was as desirable as it sounds. Of a girl of 15 her mother said typically "she wants to do more but I won't let her do it." It would seem that these 8 children, although well adjusted and in school indistinguishable from ordinary children, were rather unnaturally anxious to keep in their mothers' good books. They had to make themselves useful in order to make doubly sure of having a mother.

The Unforthcoming

The next group (again of 8) came in the category of unforthcoming children. At school they were of the well-known type of "timid mousy" backward child, and this trait was really the key to their backwardness, for they lacked the confidence to face the uncertainties of learning. These 8—except the one who was still in a children's home—were even more anxious to help their mothers than were the first group.

It was quite evident that these children's efforts to please their mothers had reached the stage of anxiety. What is more difficult to decide is whether this was due primarily to their separation from their mothers in early life or to their early illnesses and other hardships. Among the sample of 141 backward children there were also 28 who had had severe illnesses in their early years *without* going into hospital or being otherwise separated. 15 of them had the same sort of unforthcoming characters as the separated children and 8 more were maladjusted or unsettled. That is to say, the non-separated children happened as a group to be about as maladjusted and somewhat more unforthcoming than the separated ones, but in a small sample such differences would be hardly significant.

The large overlap between children who had early illness and those who had been separated from their mothers makes it impossible to do more than sense which of these experiences is primarily responsible for the emotional maldevelopment. In the whole group of 141 "backwards," 51 were assessed as unforthcoming characters. Of these 20 were separated, for one reason or another, for at least one week in their first two years. In the same period of their lives 33 had at least one serious illness or its equivalent (born weakly or ill, needing medical attention owing to failure to gain weight in first months, gross physical neglect, convulsions or a fairly serious accident, burn or scald). In 16 of the "unforthcomings" there was neither separation nor serious illness under 2 years, but in these some of the above *factors* occurred after that age, and in others there was a history of changes of mother-figure, divided maternal attachment, or other anxiety-producing family situation. (The quantitative data on which this paper is based are summarised in the table.) In weighing the relative influence of early separation and early illness it is relevant that of the above 51 "unforthcomings" only 2 were separated without being ill, while 15 were ill without being separated. This suggests that the early illnesses more than the separations were responsible for the later unforthcomingness and anxious over-attachment to the mother. People are normally lacking in "go" after being ill; with these children the severe early illnesses may have robbed them of assertiveness and made them mother-dependent over most of their childhood.

To return to the group of unforthcoming "separated" children under consideration, one noticed in 2 of them that, while being very helpful, they were not demonstratively affectionate to their mothers.

A girl of 12, who was in hospital for four months from 1 month old, was described as "never a cuddlesome baby at all." "She has always been a child to creep into a corner on her own." In her case the mother had three children in close succession, and this child was the middle one, with a sister eleven months older and a brother ten months younger. The mother admitted that with three babies so much of age "You can't give individual attention." Thus the child, who was discharged from hospital still poorly and covered with sores, probably did not get the subsequent mothering that a sick child needs.

With a boy of 13 there were more serious indications of affectual inhibition. As a toddler he had been some eighteen months in hospital and convalescent home, where he forgot his mother and became attached to a nurse. Afterwards he would not take to his mother, went down the garden as far as he could go to play on his own, became a wanderer, and got a bad reputation in the neighbourhood for destructiveness and pilfering. But his mother had given birth to another child the very day he returned from his long stay in hospital, so that the homecoming must have been inauspicious. Also she had the unfortunate habit of using threats to put him away when he was naughty, and for two years he had been waiting to go to a residential school. It would thus seem that there was enough insecurity about his situation, as it was then, to account for his unsettledness at home, although his early separation is likely to have made him more sensitive to his mother's threats and to the prospect of being separated from her again.

The Unsettled

The next group, of 5 children, were unsettled both in school and in their homes—i.e., they showed definite signs of maladjustment, though not enough to justify classifying

SUMMARY OF QUANTITATIVE DATA

Total sample of backward children of ages 8–15 years	141

Social Adjustment *
(contemporary)

Maladjusted	34 (24%)
Unsettled (lightly maladjusted, very restless, &c.)	20 (14%)
Unforthcoming	51 (36%)
Specific tension with otherwise fairly good adjustment	5 (3½%)
Stable	31 (22%)
	141

* Assessment of adjustment made on the Social Adjustment Guide (Day-School edition).

Early History of 51 "Unforthcomings"
(0–2 years)

Separated from mother at least one week	20
Serious illness or equivalent	33
Neither of above	16
Separated without being ill	2
Ill without being separated	15

Social Adjustment and Long Separation

Separated from mother at least ten weeks in first four years (mostly in hospital)		Seriously ill in first two years but not separated from mother	
Stable	8 (0)	Stable	2
Unforthcoming	8 (0)	Unforthcoming	15
Unsettled	5 (1)	Unsettled	3
Maladjusted	4 (3)	Maladjusted	5
Total separated	25	Total ill but not separated	25

The figures in parentheses give the numbers separated under 4 years of age, but without being seriously ill so far as is known—except for physical neglect. 9 children were separated a month or more under the age of 4 without serious illness. Of these 4 were unforthcoming and 5 were maladjusted.

appointed themselves by opening up a single-handed practice, while a small number came into the service through vacancies advertised by local executive councils Over 60% of doctors in general practice in the service were working in partnership and they appointed their own successors and their own replacements Single-handed practices, which were large enough to be retained as such, were advertised and went to doctors in open competition Clearly it could not be laid down that any particular doctor, employed or otherwise, must have an automatic right to a vacant practice

The number of doctors in practice was certainly not decreasing In 1955 259 practices had become vacant owing to death, retirement, or resignation 117 successors were appointed, 17 practices were amalgamated with other small practices, leaving a residue of 125 dispersed Some of these were single-doctor practices which had been given up owing to the death of the doctor Of the practices dispersed, 40 had no patients on their lists, 51 had under 300 patients, and 14 had lists of 700 or more, but in most of them certain significant factors applied, such as diminishing population During the year 613 doctors were admitted to the list to practise in partnership Of these, 297 were assistants entering into partnership in practices where they were already working

Most of the doctors recently registered for unemployment benefit were registered for under 13 weeks and only 2 for over 26 weeks There were great difficulties in finding vacancies for some of the 35 unemployed doctors Some were severely disabled

In some spheres, however, there was still a shortage of doctors The number of doctors employed in the hospital service in England and Wales which it was estimated was about 13,500 in 1949, had risen by 3000, and was still rising In many areas it was difficult to find registrars, junior hospital medical officers, senior house-officers, and house-officers Some senior registrars had had difficulty in obtaining consultant appointments, especially in general medicine, general surgery orthopædics, and obstetrics and gynæcology In anæsthetics, radiology, and mental health there was still a shortage of candidates for consultant posts

While there was evidence of some maldistribution of medical man-power as between the specialties there was no evidence of any real unemployment among doctors generally The Waverley report made it clear that the medical branches of the Armed Services had been unable to recruit enough medical officers for regular and short-term commissions In England and Wales in 1955 there were 84 advertised vacancies in general practice and the average number of applicants was 43 Many of the applicants were already in practice and were applying for what they thought was a more favourable area In the north of England there were often as few as 10 applicants for a vacancy, in the south the number might reach 100 There were only about 1500 assistants working for general practitioners in the service and it was clear that the turnover from assistant to principal was normally quite fast Of the assistants who had been in post for one year or two years in 1954 there were 53% who changed their status Nearly 75% of the assistants were in the age-group of 30 to 35

Because of the future possibility of an over-production of doctors a committee on medical man-power had been set up under the chairmanship of Mr Henry Willink to study the future needs of the service, and perhaps the expansion of certain specialties, such as mental health But the evidence which the Ministry had at present did not warrant the suggestion that there was severe unemployment among doctors

QUESTION TIME

Fall in Milk Consumption

Replying to a question, Mr HEATHCOAT AMORY, Minister of Agriculture, Fisheries, and Food, said that production of milk in the first three months of this year had increased much more than consumption and the amount of milk becoming available week by week was causing anxiety to the Milk Marketing Board The average monthly consumption of fresh milk in 1951 was 130 57 million gallons and in 1955 126 36 million gallons The Milk Marketing Board, through the National Milk Publicity Council, were taking vigorous steps to encourage sales of milk and the Government were supporting the Council In answer to a further question, he added that the Government felt they could not justify subsidising an article, even an article as good nutritionally as milk, to the extent to which they had been subsidising it to every man, woman, and child in the country, regardless of means and needs

Milk Tablets in Schools

Replying to a question, Mr DENNIS VOSPER, parliamentary secretary to the Ministry of Education, said that 129 schools were now being supplied with milk tablets as a substitute for liquid milk Apart from 18 small isolated schools which no one was prepared to supply, 111 were in Blackpool and Newport where the local education authorities had been unable to obtain fresh milk at a reasonable price It was the desire of the Minister that liquid milk should be supplied, but there were cases where this was not always possible

Pensions for Elderly Doctors

Replying to a question, Mr R H TURTON, Minister of Health said that about 800 National Health Service doctors were still in practice who were over 61 years of age when the National Health Service Act came into force These doctors could not satisfy the ten year qualifying period for a pension Those with five years' service might, however, qualify for a lump sum retiring allowance Under the regulations he had no power to do anything for those with less

Abolition of Flogging

Replying to a question, Major GWILYM LLOYD GEORGE the Home Secretary, said that the tendency was definitely for the crimes for which flogging was formerly awarded to drop Though there were queer fluctuations from year to year this tendency persisted Before corporal punishment was abolished as a judicial penalty in September 1948, the principal offences for which it could be imposed were robbery with violence, armed robbery, and robbery in company with others The number of these offences known to the police since 1946 were

1946	804
1947	842
1948	978
1949	860
1950	812
1951	633
1952	790
1953	754
1954	604
1955	578

Average Cost of Prescriptions

Replying to a question, Miss HORNSBY SMITH said that the average cost per prescription in England and Wales was *4s 4 87d* for February, 1956, compared with *4s 2 09d* for *February, 1955*

Certification of a Mental Defective

Dr BARNETT STROSS asked the Minister whether he had noted the case of Vivienne Donger, now at Stallington Hall Stoke on Trent, who was alleged to have been certified as a mental defective at the age of 11 years, only because her parents had parted and she later was considered to be educationally backward, and if he would bring these facts to the notice of the Board of Control —Miss HORNSBY SMITH replied The grounds for certification in this case were that the girl was mentally defective and the subject of a report under the Education Acts that she had been found incapable of receiving education at school The Board of Control are satisfied that for the present she needs the care and training provided under the Mental Deficiency Acts Dr STROSS Has the hon Lady seen the type of letter which this girl is alleged to have written and which was published recently in a Sunday newspaper? If so, does she think it is the sort of letter which a mental defective could write?—Miss HORNSBY SMITH I have seen the press item referred to This girl is being tried out on employment in domestic service, and if that is satisfactory further consideration will be given to the case Dr STROSS If there be substantial grounds for believing that this girl was wrongly certified, how are we to have any protection to ensure that this type of thing does not take place frequently?—Miss HORNSBY SMITH The hon Member has missed the point I made in my initial reply This girl was certified as a mental defective after being found incapable of receiving education at school, which is the normal process The procedure was not on the basis which the hon Member implied are that it acts as a predisposing factor to anxiety. Without other adverse factors the child may become oversensitive to the loss of its mother and its family—that is to say, develop into an over good, over-helpful, over-loving anxious child. If other adverse factors are present the early separation seems to contribute to the maladjustment, or to reinforce the unforthcomingness resulting from severe early illness. The effect of a spell in hospital or in an institution, provided it is not unduly long, seems to depend largely upon attendant circumstances—notably traumatic events such as painful or terrifying experiences, pre-existing anxiety about loss of the mother, or inadequate mothering in the immediate post-hospital period. In short the context of the separation in the child's emotional development is more important than the bald fact of separation in itself.

The effect of *long* separation seems to be no more and no less than that of a period in the child's life when it is deprived of family security. There is nothing special about it which takes it out of our formula, except that the earlier a bad experience the greater impression it would presumably make upon the child. It was seen with the first group of stable children that even a long period of separation in early life may have few upsetting effects if the mother has given good affection and has been loyal to the child during the remainder of its life. With the unsettled group the separation appeared to be partly responsible—perhaps as a starting-point of insecurity because circumstances were unfortunate, perhaps as a contributor along with other unfavourable factors. In these cases there was evidence of the child having suffered from the early separation. It was on the other hand noticeable that serious unsettledness or maladjustment pointed to something being wrong in the child's contemporary life. We may conclude that early unfavourable experiences may make a child temperamentally sensitive, insecure, and lacking in confidence, and possibly even leave it with a capacity for effectional inhibition; but it is what has been happening to a child in more recent years that makes it maladjusted.

There is consequently no need for undue alarm and anxiety about separating children from their parents when this is necessary. At the same time the potential harmful effects should be recognised and minimised.

Preventive Measures

In such preventive work it may be useful to consider three categories of children.

Short Separation

In the first are those who will normally return within a few weeks or months to their own homes. These include children in residential care for a special reason, such as an illness or nervous breakdown of the mother. Children who go into hospital for a relatively long time will also be in this category. With the latter the ideal solution is that the mother should go into hospital with the child; and though this is usually difficult for domestic reasons it should be arranged, whenever practicable, when the treatment is likely to be painful or frightening. With children temporarily in public care this solution is nearly always ruled out, because the mother's unavailability is the reason for their being there. With ordinary hospital cases, if the mother can visit every afternoon or at any rate three to four times a week, this should largely overcome any bad effects. Alternatively, if the mother cannot visit, the other members of the family should do so as frequently as possible.

Another measure indicated by the cases quoted is that we should attend to the manner in which the separated child is reunited to its family. If it has been away a long time and has been kindly looked after it will naturally have taken to some extent to the staff of the hospital or institution, and its mother will be a bit of a stranger. This, then is the period of maximum sensitivity, when harm can be done if the child does not receive a warm and unpreoccupied welcome from the mother. It is not good enough to notify a mother that her child is ready for her to collect on a certain day; we should ascertain that she is available, in good health, and emotionally prepared to welcome it. It is also our duty to help mothers understand the emotional readjustment which a child has to make upon its return home, and to see that she is not disappointed if the child does not take to her immediately.

Long Separation: Contact Retained

The second category consists of those children who are more or less permanently in an institution but remain in touch with their families. A child is probably affected more fundamentally by his feelings about his family than he is by his day-to-day life in the institution. We should therefore regard the guidance of child-family relations as an important point of our work. This means doing our best to ensure that the parent or other relative visits frequently, does not fail to turn up or lightly postpone visits, and brings in whatever little luxuries can be afforded. If the parents are at a distance we should try to prevail upon them to write frequently. Incidentally many children are known to have relatives but these never think of contacting the child, or do so once in a while; in many cases we ought to persuade them to become active "aunties" and "uncles." Any reputable relative is of tremendous value to a child in giving it a sense of having a family.

One of the difficulties is that mothers or relatives left with orphaned children want to keep the girl but not her brother. If the latter only is placed in an institution he is very likely indeed to resent it bitterly and become the hostile-anxious sort of maladjusted child. Perhaps we should insist where possible upon both or neither of the children being taken into care.

Contact Lost

With the third category—those children out of touch with their relatives—we have to provide the nearest thing we can to a feeling of belonging to a family. I do not think this so hopeless as it may sound, but it will probably entail big changes in the organisation of some homes. We need not necessarily try to imitate the special type of self-contained small European family. The traditional Indian household and the African family are larger units. But all families, even though numerous, have their own structure of human relationships; each individual has his special place according to sex and seniority, and there are other members who are specially near him or her. A home of some 20 boys or girls, more or less of the same age, with house parents and one or two assistants, is not structured in this sense and so none of the children can feel that they are the special concern of any of the senior members of the group. The family-group basis into which some homes have been so successfully broken up is going a long way in the right direction. To carry the idea to its logical conclusion, the family group should be a mixture of ages and sexes, so that boys and girls from babyhood to leaving age would be in the same "family." This would enable us to dispense with the nursery institutions, and the presence of a baby in the group has been found to have a settling effect upon the older boys and girls. To follow this idea of the structured, diverse group further, we should so far as possible avoid communal eating, daily assemblies, or daily outings *en troupe*. This of course would not bar the occasional corporate gathering or excursion, which might be compared to the tribal assembly which gives a sense of being part of a powerful parent-body. That, by the way, is one of the things that a voluntary home can offer which a local authorities' home cannot.

A further difficulty we have to face is that of staff leaving; and the more family-like we make a group observations in that case were—subject to the effect of the Rules of Procedure—applicable to such a case as the present where the conviction, not having taken place in the United Kingdom or the Republic of Ireland, was only prima facie evidence of the infamous conduct alleged In so holding their Lordships had not lost sight of the changes produced by the Medical Act, 1950, in the position of the Medical Disciplinary Committee, as compared with the General Medical Council under the Act of 1858 The committee, however, were not *a court of law but a domestic forum charged in certain* cases, of which the present was one, with the peculiar duty of making "due inquiry" into the circumstances attending the conviction in a distant country of a medical practitioner with a view to deciding—of which they alone were the judges—whether he had been guilty of infamous conduct in a professional respect That duty they could not adequately perform unless they were in possession of the whole of the proceedings in the criminal court in which the conviction occurred It would be unfortunate if they had precluded themselves from so functioning by the rules, and in particular by rule 63 The record of proceedings was, in their Lordships' opinion, a "document" within the meaning of the second limb of rule 63 The admissibility of such documents was, however, limited to the statements of fact contained therein, and such a restriction might render the task of the committee and legal assessor extremely difficult in dealing with the record of proceedings in the criminal court and would exclude the judge's charge to the jury and other parts of the record which it was clearly desirable the committee should see

In the present case the record, with certain excisions, was put in by consent as soon as the committee had quite properly decided that the attendance of the witnesses from Malaya was not practicable and that their absence did not vitiate the proceedings The consent to the admission of the record was fatal to any objection on that score now being put forward, nor did their Lordships consider that there was any substance in the contention that the whole of the evidence was not read out in court Their Lordships desired, however, to draw *the attention of those concerned to the desirability* of an alteration in the Rules of Procedure whereby the committee could be empowered beyond all question to receive in evidence and examine the whole of the officially authenticated proceedings of the convicting court in this class of case

There had been no miscarriage of justice in this case and their Lordships had accordingly humbly advised Her Majesty that the appeal should be dismissed

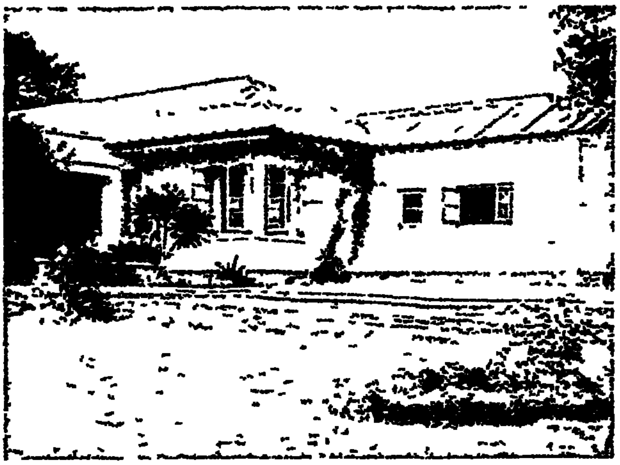
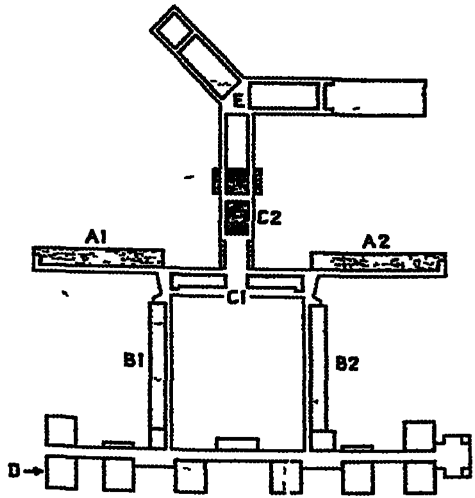
The courtyard of the future hospital



Part of one of the staff houses

those for clinical training in the two existing hospitals of Ibadan were not of the requisite level. Accordingly the government of Nigeria decided in 1951 to press forward with plans for the building of a separate teaching hospital, associated with but administered independently of the University College. Meanwhile the University of London, as an interim measure, agreed to make room for Nigerian students for clinical study in British medical schools until it should be completed.

In Nigeria, of course, there are fewer difficulties about space than would have to be faced in planning a great new teaching hospital in this country; and the board of management, in acquiring a site not far from that of the University College, were able to plan with reasonable freedom. When the hospital is finished, it may well be the envy of clinical teachers in some of our own medical schools.



Plan of the hospital

Building began in 1952 and progress has been such that at the time of the visit of the Queen on Feb. 14, the hospital was assuming something like its final shape. Its occupation is expected to begin this year and clinical teaching in October, 1957. Besides the teaching of students, the hospital is also to provide research facilities for the medical faculty; a school for the training of nurses up to the standard prescribed by the General Nursing Council has already been established and the first group of students has qualified.

No expense is being spared to make the hospital, both in standards and equipment, fully comparable with teaching hospitals in the United Kingdom. Grouped around the main building—each a notable example of modern design—are the ancillary departments. These include the medical school and hostel for clinical students, a school of nursing, a nurses' home, a school of hygiene, a resident medical officers' hostel, sisters' quarters, and housing for medical, administrative, and technical staff.

As shown in the plan which we reproduce, the hospital itself consists of eight blocks. Blocks A1 and A2 have five floors, while blocks B1, B2, and C1 have six floors, including a lower ground floor. Block C2 has eight floors, including a lower ground floor, whilst blocks D and E consist of ground floor and lower ground floor only.

On the ground floor, the board room and administrative offices are housed in blocks C1 and A2, the casualty department in B2, an X-ray department in C2, and laboratories in A1 and B1.

The wards for inpatients are on the upper floors of blocks A1, A2, B1, and B2, and the professorial units on the upper floors of C1, while the air-conditioned operating-theatres, the cardiographic department, and the central sterilising department are in C2. A hall with provision for eight lifts is also included in these latter blocks.

A spacious outpatient department is located on the ground floor of block D. This floor also contains the pharmacy, almoners' offices, and patients' record department; a physiotherapy department and an antenatal clinic are on the lower ground floor. Block E houses the kitchens, laundry, boiler-house, and staff dining-rooms.

When complete, the hospital will have 490 beds. Of these, 116 will be medical (including 28 for dermatological and neurological cases); 144 surgical and orthopædic (including 28 for septic surgical cases and 28 for ear, nose, and throat and ophthalmic patients); 109 obstetric and gynæcological; 68 pædiatric; and 28 for tuberculosis and thoracic surgical cases. There will also be 23 cots for sick babies and 2 observation (metabolic) beds; in addition 14 recovery beds adjoining the operating-theatres and 6 labour beds are envisaged.

The new hospital, besides providing for the training of students, will more than double the number of beds available for inpatient treatment in Ibadan. But University College Hospital will, it is hoped, do more than serve the local needs; as the centre of the country's medical life, it will provide a consultant service for the treatment of difficult cases throughout Nigeria, stimulate research, and play a vitalising part in the hospital services as a whole.

Naturally the cost of this great undertaking has been high, and according to current estimates a total capital outlay of £4½ million will ultimately be required. But it is a remarkable tribute to the determination and foresight with which the federal government are facing their responsibilities that the whole of this sum is being provided exclusively from Nigerian resources. At the moment the number of students entering the medical school is small, numbering only 30–40 a year. The new hospital is a sound investment in that it will both

Royal College of Physicians of London

At a comitia held on April 26, with Sir Russell Brain, the president, in the chair, it was announced that the Wellcome Trustees had given £40,000 as an endowment for research into the history of medicine, and £6000 towards the extension of the college building, as well as a grant towards a new edition of the Harvey film in colour which will be made by the Foundation's film unit

Royal Medical Benevolent Fund

The annual general meeting of this Fund is to be held on Tuesday, June 5, at 5 P M, at 11, Chandos Street, London, W 1

Institute of Dermatology

A semi permanent exhibition by Dr I Friedmann on diseases of the nose and ear in relation to dermatology will be held at the Institute, Lisle Street, W C 2, from May 7 to 25

Heroin Banned in Italy

By a decree, entered in the official gazette of the Italian government (March 24, 1956), the manufacture and importation of heroin has been prohibited in Italy

Royal Society of Arts

On Mondays, May 7, 14, and 28 at 6 P M, at the society's house, John Adam Street, London, W C 2 three Cantor lectures will be given on Recent Studies of Sociology On May 7, Prof T S Simey, M A, will speak on Class Conflict and Social Mobility On May 14, Prof D V Glass, PH D, will speak on the Development of Demography The last lecture will be given on May 28 by Dr R F Tredgold, whose subject will be Changes in Social Responsibilities

Industrial Medicine Unit

The North West Metropolitan Regional Hospital Board have agreed that an industrial medicine unit shall be set up at the Central Middlesex Hospital It is proposed to appoint a consultant physician who will have beds at the hospital and will study the prevention of conditions in factories which contribute to the hospital load in the casualty and out patient departments as well as the wards" The Nuffield Trust will meet the cost of the unit for the first three years

Settlement of Dispute in Malta

In Malta the dispute between the government and the Medical Officers' Union (see *Lancet*, April 21, 1956, p 519) has been settled (*Times*, April 26, 1956) Doctors, after withdrawing their letters of resignation, are to be reinstated A commission, comprising a legal chairman and two members nominated by the Royal College of Physicians and the Royal College of Surgeons, will be appointed to review the medical service and the terms of employment Meanwhile no action will be taken to fill posts in Gozo or similar posts

---

The honorary fellowship of the American College of Physicians has been conferred on Dr Macdonald Critchley

this period this variety was isolated from 80 patients and 2 healthy persons 2 of the patients had meningitis, from which they died, and 78 had acute gastro enteritis Kristensen states that 17 of the patients had either eaten or been in contact with 'Ratin' shortly before the onset of symptoms, in 31 of 38 cases ratin had previously been laid out in places frequented by the patients He also found that ratin bread stored for 88 months still yielded *S enteritidis* var *danysz*

Many human infections due to *S enteritidis* occur in this country each year, it can be seen in reports on food-poisoning that this species has been the second commonest cause of salmonella food-poisoning in each of the years 1951, 1952, and 1953 (Ministry of Health 1954, 1955) *S enteritidis* can be subdivided by biochemical reactions into four varieties, of which *S enteritidis* var *jena* is the most common and *S enteritidis* var *danysz* the second commonest in this country

Table I has been compiled from information received with cultures which have been identified in this laboratory It shows that both the jena and the danysz varieties may cause sporadic infections or outbreaks Some infections were fatal, but, as with salmonella infections due to other species, some of the deaths were in patients with another disease in which the superadded *S enteritidis* infection merely accelerated the fatal issue Of 21 deaths due to *S enteritidis* var *jena* 7 were associated with one of the following diseases leukæmia, fractured femur, severe hypertension, early carcinoma of stomach, cardiac failure, pneumonia, and severe mental illness In the remaining 14 cases death was directly attributable to infection with *S enteritidis* var *jena* The danysz variety gave rise to a fatal meningitis in a patient with anæmia In another case, recorded in 1955, infection with the danysz variety caused the death of an otherwise healthy man aged 57 The clinical symptoms due to the two varieties were much the same In 1954 the history of 16 cases of the jena type showed that the duration of the illness was 2–28 days (average 10); in 4 patients with danysz infection the illness lasted 5–10 days (average 7) The symptoms in both infections were those usually associated with food-poisoning pyrexia, diarrhœa, vomiting, occasionally blood and mucus in the stools, and some abdominal discomfort or pain Although the clinical symptoms were not usually severe, in some instances there was cause for alarm A patient with jena infection was suspected of having infective endocarditis due to this organism, a patient with danysz infection had rigors, and another collapsed Though these serious symptoms are unusual they may occur, and individual patients may show any degree of severity, even to a fatal outcome, both in jena and in danysz infections

Outbreaks

Table I shows the number of outbreaks from which information and cultures were received Both the jena and the danysz varieties can cause large outbreaks In this survey an outbreak has been defined as affecting 5 or more persons and therefore has not included some smaller outbreaks Descriptions of some outbreaks are given below from reports received here and from other sources

Outbreak due to S enteritidis *var* danysz

This report was made by Dr M Avent, medical officer of health for Basingstoke, and is published with his kind permission

REPORT ON OUTBREAK OF FOOD-POISONING CONNECTED WITH BASINGSTOKE SCHOOL MEALS DEPOT

On Friday afternoon, June 8 1951, a message was received that children at Silchester, Monk Sherborne, and Ramsdell schools had been taken ill with diarrhœa and vomiting

Inquiries suggested that the illness was connected with the midday meal at school on the previous day, June 7 Reports were later received of similar illness among children at Herriard Steventon, and in the Kingsclere and Whitchurch Rural District (Hannington, Overton) and the Alton Rural District (Wield, Medstead)

Specimens from patients were examined in the Public Health Laboratories at Reading and Winchester, both of which reported the presence of *S enteritidis*, an organism commonly associated with outbreaks of this type

Head teachers in the schools give the following figures

(*a*) Schools supplied by Cooking Depot	25
(*b*) Schools reporting cases of illness	12
(*c*) Children at (*b*) taking meal	939
(*d*) Children affected with illness	346

The staff at the depot ate the same meal, and about half were taken ill 4 of them so seriously that they were off duty for several days and 3 are still away (June 20) Examination of specimens from all 4 of them showed salmonella present in 2 and they have been excluded from work at the depot till clear

Unfortunately the only material used in the preparation of the meal in question which could be obtained was some custard and a few bread crumbs, examination of which gave negative results It was impossible to obtain any of the meat which had been used in the "savoury mince" supplied that day, because it had all been disposed of

* From Domestic Food Consumption and Expenditure, 1953 (1955)

rationing, though these may have political as well as economic bases Effective rationing ensures a more even distribution of specified foods both by restricting the highest levels of consumption and by increasing the lowest levels This was achieved in Britain by the triple system of ration-books, price control, and subsidies As a result of these factors, the variation of consumption with income was much reduced for commodities such as meat, cheese, eggs, and milk I also include here the schemes for the distribution of milk to nursing mothers, young children, and school children A large part of the present high consumption of milk—nearly 40% more than before the war—is undoubtedly due to these schemes

Other Factors

Before leaving physical factors, let me refer to two others—food technology and fuel Food technology has, as we have seen, made available foods far from their origin, and far from the time of harvesting or slaughtering It has also made available new foods, some of considerable importance, like margarine

The shortage of fuel in this country two hundred years ago, and in countries like India up to the present, necessarily restricts the sorts of foods which will be eaten Thus, it will be useless to provide India today with foods, however palatable and however nutritionally desirable, if their preparation is beyond the resources of the stone hearth and cow dung fuel

Social Factors

Religion and Social Custom

The effect of religion on food choice is best known through its prohibition of the eating of pork by Jews and Moslems and of beef by the Hindu, and of meat eating on Fridays and throughout Lent by the Roman Church Vegetarianism is met with in many religions—examples include again the strict Hindu Brahmin, as well as the Jains of Indian and the Kikuyu of East Africa The origins of these religious taboos are not always clear, though early ideas of hygiene played a part, economic factors were probably in many peoples more potent causes The nutritional effects may be enormous, Orr and Gilks (1931) have shown how the vegetarian Kikuyu are nutritionally far inferior to the neighbouring meat eating Masai

Social custom may dictate a variety of strange food habits In many countries common foods may be prohibited at certain times, such as pregnancy or lactation, or during illness or mourning, or other unusual foods may be eaten at these times Insects are an acceptable food in Mexico, Nigeria, and Siam and to the aboriginals of Australia (Bristowe 1953) In Latin America, foods are divided into "hot" and "cold" (Wellin 1953) The former may be consumed at any time, the latter only by healthy adults, but not in the mornings and only if their cold effects are neutralised by hot tea Foods are also divided into "heavy" or indigestible (for example, rice, milk, dates, figs) and "light" or easily digestible (mutton, chicken, bananas, carrots) Apart from milk, young children are not given heavy foods Natural sweet foods—that is, fruits—are not compatible with prepared sweet foods containing sugar, and must not be eaten together

Such customs usually are very strong and resistant to change Jews from the Arab countries who have recently migrated to Israel greatly resented the new foods which were imposed on them by the strenuous system of rationing there Even after several years they seek every means to revert to their original food habits—to use many spices, to take rice rather than wheat, and to use vegetable oil rather than other fats (W Straus, personal communication)

Social Class

There is commonly an appreciable difference in food habits between different social classes In this countr it shows itself in a preference by the so called upp classes for brown bread rather than white, for bitt marmalade rather than sweet, for coffee instead of te for coffee without rather than with milk, for savour rather than sweet puddings, and for the avoidance such foods as kippers and tripe These preferences, however, are not static since they occur or are cultivated al in those who are ambitious to move upwards in the soci scale The reverse is seen in the Hampstead and Chelse intellectual who cultivates a preference for tea an kippers—a form of inverted food snobbery The chi difference between social classes is the increasing rang of foods eaten as the social scale is ascended It i difficult to get working class peoples to try new foods on the other hand, trying new foods is almost a prerequisite of the socially superior The origin of thes customs is clearly economic

Education in Nutrition and Hygiene

Here I include those ideas of food values and food hygiene, whether sensible or nonsensical, which a group, a school, a society, or even an individual actively propagates As examples of hygiene propaganda, I may quote the acceptance by most people of pasteurisation of milk as a sensible hygienic measure (which it is) or of leaving foods in tins as hygienically dangerous (which it is not) Sometimes, sensible nutritional propaganda is effective, and it is possible that some part of the present high consumption of milk is due to the acceptance of propaganda that milk is a nutritionally desirable food We have seen, however, that probably a greater part o this high consumption is due to imposed State policy Somehow, it seems easier for people to accept foo nonsense than food sense It may be quite difficult t persuade people to drink milk and eat vegetables and fruit, but much easier to persuade them to take yogurt molasses, brewers' yeast, and wheat germ, or to eat their meat and their potato at separate meals Fortunately it is often true that the vogue of these fashions i usually amongst the wealthy members of the community who are likely, almost without wishing it, to take wha eventually adds up to a reasonably adequate diet Bu there have been examples where restrictions of foo choice imposed by one or other of these fads have prove harmful to those who have been duped

It would be interesting to speculate on some of th underlying reasons which make people susceptible to th sort of propaganda Let me mention only one—th hankering after naturalism Probably as a reaction t some of the less pleasant manifestations of civilised life it is easy to persuade people that natural foods are likel to be superior to sophisticated foods Hence the conviction amongst many that fresh vegetables are nutritionally superior to canned vegetables, or that butter i nutritionally superior to margarine, neither of thes statements is true

In general, however, food habits as we have seen ar established so early in life and so firmly that they ar little affected by propaganda When new knowledge i accepted at all, it tends to become moulded so as to fi the existing culture Thus, villages in Peru to whic something about vitamins has percolated have kept t agriculture, made certain recommendations about using bacterial rodenticides (Toxic Chemicals Working Party 1953) These recommendations were the least which could be accepted, and, in my opinion the use of bacterial rodenticides is unjustified because they may infect man and animals they may constitute an uncontrollable source and chain of infection of long duration, and they are said to be not so effective as other methods of controlling rodents

The use of bacterial rodenticides is banned in the U S A

Summary

In this country between 1944 and June, 1955, *S enteritidis* var *jena* accounted for 1267 known cases of infection in man of which 21 were fatal, and *S enteritidis* var *danysz* for 413 cases, of which 2 were fatal

In animals *S enteritidis* var *jena* was isolated most commonly from guineapigs, mice, and pig glands, and *S enteritidis* var *danysz* from rats, guineapigs, and mice

The use of bacterial rodenticides containing either of these organisms is no longer necessary and should be stopped

Air Pollution

Logan[1] has estimated that about 1000 people died in the Greater London area as a result of the fog of Jan 4–6 this year The fog of Dec 5–8, 1952, was responsible for some 4000 deaths in London[2], and as Logan reminds us this January's episode is the third major fog incident in London since 1948 Unhappily, further incidents can be expected so long as air pollution continues at the present rate. Indeed, we may expect things to get worse as more people, houses, industries, and petrol and diesel vehicles are gathered together

London fogs have no exact parallel elsewhere Previous episodes (such as those at Donora and in the Meuse Valley, or the eye-smarting annoyances of Los Angeles) are very different from the wet thick smog of London Drinker,[3] in an arresting article, remarks that Londoners have looked upon "pea-soupers' with a sort of friendly familiarity not shared by strangers He recalls the two gentlemen who collided in Hyde Park during the 1952 fog 'With the formal politeness characteristic of the English, one said 'I beg your pardon. Can you please tell me where I am going?' The other replied, 'Yes, I can—into the Serpentine I have just come out'"

The Clean Air Bill which is based on the Beaver report, is now over some parliamentary hurdles Its far-reaching provisions show that Parliament, and we hope the public mean business now as well as in the near future The cure for our ills is not easy, and much money and trouble must be expended We must face the fact that we just do not know exactly what it is that makes smog lethal Amdur's valuable work on sulphur dioxide has been criticised and further research is a matter of the first importance Drinker draws attention to interesting observations by Clayton[4] and others on the use of radioactive isotopes to 'tag" fuels like coal and motor fuels and thus enable their presence to be detected in the air This method might help us to decide whether sulphur dioxide and smoke in this country come mainly from domestic fires from power-stations or other industrial sources or from motor exhausts

Electricity power-stations have been accused of pouring out huge quantities of oxides of sulphur But in a paper read in New York Rees,[5] of the British Electricity Authority discusses the effects of the ban put on "scrubbers' (for removing sulphur dioxide) during the late war because the effluent streams were steamy and made good beacons for enemy aircraft and claims that there is insufficient evidence to justify a return to the pre-war practice of scrubbing and that nobody can measure the difference chemically or by health surveys whether or not the sulphur dioxide is scrubbed out Since the process is very costly, those in charge of the power plants are opposed to its use

In many ways, London is far behind some other large cities which have recently 'cleaned' their air Pittsburgh for example handles enormous quantities of raw materials in its steel mills and blast-furnaces, whose activities caused much pollution by ash, grit and carbon particles It can certainly be proud of its anti-pollution drive and can point with satisfaction to the fact that a transatlantic plane was recently unable to land anywhere near New York or Boston because of poor visibility but was accommodated easily at Pittsburgh Some less effective preventive measures have been taken in this country Last winter the Government supplied masks to those with bronchitis asthma, and cardiovascular disease and these helped many patients to breathe less polluted air Elderly persons were advised to remain indoors and if possible to rest But little has so far been done to get rid of the cause or causes

The scientist, the combustion engineer and the local authority must get together to change our traditional methods of heating Compulsion may have to be used for Government reports and exhortations have proved to be largely ineffective At least one line of research must be pursued further Wilkins, of the Fuel Research Station, has devised an adjustable wick dipped into a bottle of ammonia as a means of neutralising both the sulphur-dioxide gas and sulphuric-acid mist This method may protect humans in the same way as the pigs and sheep at Smithfield Show were protected during the 1952 fog The scrupulously clean (and therefore non-ammoniacal) animals were seriously affected whereas those less meticulously cared for were unharmed.

Vaccination against Poliomyelitis

The initial batches of the British poliomyelitis vaccine have now passed their safety tests and will be used for first injections to about 200 000 children in Great Britain These will be children born in November of each of the years 1947–54 and in March of the years 1951–54 These children will receive first injections shortly, and after about three weeks second injections Any vaccine left over from this first distribution will be used for children born in August of the years 1947–54.

In the first phase of the vaccination programme, in May and June, it is hoped to vaccinate over 300,000 children in England and Wales and 40 000–50,000 in Scotland The remainder of those registered will be given priority when vaccination is resumed in the autumn

Children registered for vaccination number 1 610,899 in England and Wales and 299,144 in Scotland—29% and 42% of those eligible Returns were received from 144 of the 146 local health authorities in England and Wales and from each of the 55 authorities in Scotland choose his diet wisely Since observations on man have not given us any completely satisfactory explanation of this, let us turn to the experiments on animals

[4] Clayton G D Arnold, J R. Patty, F A *Science*, 1955 122, 751

[5] Rees R L Proceedings of 1st International Congress on Air Pollution, New York, March 1955 p 143

The most important and by now classical experiments in this field were those reported by Harris and his collaborators from Cambridge (Harris et al 1933) They found that rats depleted of vitamin B_1 will choose a diet containing it in preference to one that does not An animal may be sufficiently confused by a wide array of possible choices that it cannot select, but it can be taught to recognise the correct diet Again, it may be deceived by giving it a deficient food with a flavour which it has previously learnt to associate with the vitamin-containing food, but once more it can be re educated to the correct food

Harris explained these findings on the basis of learning The condition of the deficient animal is so rapidly improved when he eats the right diet that he soon learns to associate this with the resulting feeling of well-being

Since that time, many examples have been reported by other workers of the ability or otherwise of animals to choose a correct diet (see Lepkovsky 1948, Scott and Verney 1948) Adult rats, offered a diet of pure nutrients in separate containers—for example, five containers with protein, fat, carbohydrate, mineral elements, and vitamins—can select an adequate diet, they do not do so, however, when they are very young or during pregnancy or lactation Rats rendered deficient in vitamin B_1 or riboflavine or pyridoxine or calcium select an adequate diet, but rats rendered deficient in protein or vitamin A or vitamin D do not do so If deprived of the adrenal glands, an operation whose effects are relieved by taking salt, they would choose a salt-containing diet If deprived of their pancreas, a condition relieved by avoidance of carbohydrates, they reduce their intake of carbohydrates And finally, we have recently shown that rats deprived of vitamin B_1 reduce their intake of sugar, some avoiding it entirely and surviving for long periods

All of these results support the view of Harris that a deficient animal learns to choose the correct diet when by so doing he rapidly feels better Where the deficiency is of a nutrient like vitamin A, or vitamin D, which does not lead to a correct choice, the explanation is that the correction of the deficiency does not produce improvement rapidly enough for the animal to learn to associate the improvement with the food which gave rise to it Even one apparent exception to this supports the learning theory Animals rendered deficient in magnesium *avoid* diets containing this element, it seems that magnesium deficiency results in a sort of intoxication which the animals find pleasurable, and that they learn to avoid eating magnesium in order to preserve this sensation

It has been suggested that nutritional choice is brought about by some inner drive or instinct by which the animal is made to seek out a food containing the appropriate nutrient (Richter 1947) My own reading of the evidence at present available is that the theory of learning, as developed by Harris, is much the more likely explanation

One more animal experiment is worth quoting If animals from whom the adrenal glands have been removed are offered a choice between water and a salt solution, they choose the salt and so live much longer If, however, they are offered a choice between sugar solution and salt solution, they tend to take the sugar, and die sooner (Harriman 1952) We can therefore modify Harris's theory to the extent of saying that a wise nutritional choice may be prevented if a sufficiently palatable but nutritionally unsuitable food is offered too

What then are the general conclusions we may draw from such animal experiments ? First, animals presented with individual nutrients are sometimes able to select these in such a way as to satisfy their nutritional needs Their ability to do so depends on age, physiological state—e g, whether or not they are pregnant—and heredity, and some do it better than others

Secondly, a deficient animal will select the missing nutrients, and perhaps also avoid harmful ones, if the beneficial or harmful effect is fairly considerable and occurs fairly quickly

Thirdly, it seems to follow from this that the correct choice of individual dietary items is not due to an instinctive urge but to learning that animals learn to associate the consumption of the right food with the feeling of well-being induced by it This would also explain why people have come to like alcohol or tea or coffee or cola

Fourthly, a nutritionally wide choice may be diverted to one which is unwise or even fatal by offering a palatable but, in the circumstances, worthless food

These conclusions, interesting as they are, still do not provide the whole answer They do not explain why man, with quite different foods at his disposal in different parts of the world, is usually capable of showing nutritional wisdom in his choice of food, provided he is not limited, by, for example, economic circumstance or by nutritionally unsound social pressure

A possible explanation might be that it is a result of experience By experience, translated into and transmitted by social custom, man has learned what foods to select to maintain reasonable if not perfect health That is to say, the food habits of a people, which begin to be formed from the moment of birth, have been built up on the experience of previous generations who themselves have learnt by trial and error

But to my mind this is still an inadequate explanation I believe that the key to the understanding of food selection according to physiological need is something which might be called the hypothesis of satiety If to this is added an extension of Harris's theory of learning, and the possibility of cultural transmission of patterns of food selection, then I think we can explain the phenomenon completely

I derive the hypothesis of satiety from the observation —common to all the experiments on food choice with human beings and animals—that no person or animal will consume only one article of diet but always takes some from all or at least several of the sources available Consider the experiment of an animal offered an array of pure nutrients He eats a little protein, then some carbohydrate, then perhaps some fat, then more protein, in due course he consumes—or at least *often* he consumes —a nutritionally sound mixture of all the essential nutrients The question why he will choose to eat vitamin B_1 if he is short of this vitamin we have already answered But there are two further questions which are not answered by the learning theory First, why does the deficient animal *stop* eating the missing nutrient after a time, and move on to another ? Second, and even more important, what determines food choice in the non deficient animal ? We must accept that, with a reasonably wide variety of nutrients or foods from which to choose, the animal often makes a good enough choice to avoid deficiency altogether He does not, as it were, wait until he is deficient in vitamin B_1 before taking this nutrient The constant choice of an adequate diet, by man or animal, clearly therefore cannot depend on a sequence of specific nutrient deficiencies and the subsequent learning to eat the foods which correct them

I suggest that these questions may be answered somewhat along these lines The increase in consumption of a particular food, or of a pure nutrient, leads first to the pleasant sensation of satiety, but beyond this to an unpleasant sensation which makes the animal stop eating this food This unpleasant sensation, such as we might get by eating too much sweet or fatty food, might perhaps be a feeling of nausea by direct action on the stomach wall, or arise from a change of taste sensation

In England Now

A Running Commentary by Peripatetic Correspondents

ONCE upon a time there was a very poor country, where nobody had enough to eat and the average expectation of life was 24 years There was also a very rich country, where everybody had plenty to eat and the average expectation of life was 64 years In the very rich country people used to save up milk and butter and cream and eggs and send them to the very poor country, where they were distributed, especially to the children, who would otherwise have had none In this way the expectation of life in the very poor country was raised from 24 to 27 years Meanwhile the expectation of life in the very rich country was rising too, and went up from 64 to 67 years, and everyone who didn't die of cancer of the lung from smoking too many cigarettes died of coronary thrombosis Then someone discovered that coronary thrombosis was due to eating and drinking too much milk and butter and cream and eggs So people stopped eating and drinking milk and butter and cream and eggs in the very rich country, and sent it all to the very poor country, so that the expectation of life in the very poor country might be raised high enough for them to start dying of coronary thrombosis so that they, too, could stop eating and drinking milk and butter and cream and eggs

Attendance at a symposium in the spring, if not too slavish, is an effective tonic for those who live and work at the periphery If the meetings are held in London a country-dweller is also subject to the extra stimuli of continued partial asphyxia and other unaccustomed features of the bustling, abrasive way of life in the capital This year's deliberations on bacterial anatomy seemed to call for a lot of microbial vivisection of a violent kind Here were descriptions of germs with their limbs torn away in disintegrators, whilst others had their outer walls eroded by enzymes to lay bare the naked protoplast or else thickly coated with a clinging layer of antibody Some spoke of the behaviour of germs exposed to severe cold Some had tried the effects of over-heating or immersion in strong brine One experimenter confined his subjects to the airless end of a sealed capillary tube, there to swim "till the last, *nastiest amino-acid* was consumed" We were delightfully reminded here that a bat may nourish its wing-muscles on the same residue In the chamber of the micromanipulator any plump bacillus may be subjected to acupuncture, though techniques for inflicting moxibustion are still lacking If Blake had sat among the audience he might have heard the molecular screams of dismembered viruses, but the company would surely have requested the evidence of tape-recordings and an electron micrograph of the microbial mouth-parts

A non-microbiological wife (taken to reading the journals since the rising tides of inflation cut off the evening paper) was as much diverted by the appearance of the microbiologists as by the morphology of the microbes The feminine eye can at once distinguish on sight between the reliable and the untrustworthy During the respectful silence that greeted a cine-film on motility came the whispered observation that the ones with tails were clearly males, while the sleek, stationary ones must be female

The dictionary affirms that a symposium is a convivial meeting for drinking, conversation, and intellectual entertainment Considering that most of the communications can well be read in print in the comfort of a fireside-chair, is it not worth arranging such a meeting, without the set speakers, to take place in a large tent lined with barrels? Back at the periphery now, we are working on this idea whilst coping once more with the vagaries of children, pets, gardens, clinical colleagues, and the local plagues

Before he can arrive at a diagnosis, the Young Doctor must arrive at his patient (cf Mrs Glasse and her jugged hare) A major obstacle in the Practitioner's Progress is the patient's garden gate As your correspondent lately sucked his lacerated fingers, it occurred to him that this is another topic on which postgraduate education is of no help

The Englishman in this part of the Island surrounds his castle with such fortifications that it resembles the lair of an immured robber baron Concealed craftily among the defence works and composed of cutting edges fastened together by barbed wire, is the garden-gate These devices fall into two groups

1 Those that won't shut
2 Those that won't open

Group 1, very rare, is a godsend to the Y D unless he is fighting a delaying action with one of the household's paranoic dumb chums

Group 2 includes almost all gates not included in group 1 The Y D confronted with a gate *in group* 2 should not waste time attempting a parley with the garrison Inevitably the Y D will have to "go it alone" Two lines of strategy are open to him If he weighs-in at ten stone or under, let him produce his screw-driver and heavy wire-cutters and dismantle the gate The Y D in the heavier weight-classes is advised "to retire in order to jump the better," and with (or without) a hoarse shout of "A Nye! A Nye!", to hurl himself at the gate He will then either descend into the garden in a cloud of disintegrating wood and metal, or find himself rushing up the garden path carrying the entire gate before him, with a bow-wave of prams, milk-bottles, toys, and juvenile delinquents

It should now be obvious why the assault direct is contra-indicated for the light-weight Y D The gate may be so resilient that he rebounds violently across the pavement If lucky, he will merely drive his occiput through the side-window of his car, and the resulting scalp-wound should heal nicely in about ten days If unlucky he will disappear under a passing bus In either event, there will be Delay in Seeing the Patient

* * *

The Ganglion has been promoted at about the same rate as I have In those bad old days when I started as a casualty dresser *we students were set to work dissecting* them out in the outpatients' theatre during the afternoons By the time I was a house-surgeon it was recognised, and how rightly, that this was not good enough, and I was again set to work during slack afternoons dissecting out ganglia, this time in the main theatres Now that I have struggled into the ranks of the senior registrars I find that the ganglion is considered too strong meat for the house-surgeon and it appears once more on my list Among the consultants the waiting-lists grow short The heroics of the operating-theatre recede, and their places will soon be taken by humbler activities that once would have been thrown as crumbs to the registrars I see *no escape Ganglion, you are my fate*

* * *

About five years ago I was digging in my garden on a very warm spring day when a little elf appeared He offered to finish my digging for me, and I was only too glad to sit in the sun in a deck-chair on the lawn Well, he soon finished that off *and started clipping the hedge* To cut a long story short, he offered to look after the whole garden; and from that day on I never had to do a stroke I used to sit out under a tree with a glass of beer and the newspaper, and the industrious little elf used to dig and delve from crack of dawn till dewy eve He was a real glutton for work The garden had never looked so neat and well stocked, I was the envy of my neighbours for miles around

Then two years ago he suddenly stopped coming Didn't say a word, just didn't turn up I was lost The garden went to wrack and ruin It was a wilderness Yesterday he turned up as though nothing had happened and started working No *apology or anything* I was livid "Look here," I said, "where do you think you've been all this time?" "I been for me National Service," he said "And what sort of National Service do you do, my little man?" "What? Ain't you never '*eard* of the National Elf Service?" he replied

A patient's comment on the exhibition of the Medical Art Society—Never before have so many doctors done me so much good at one visit

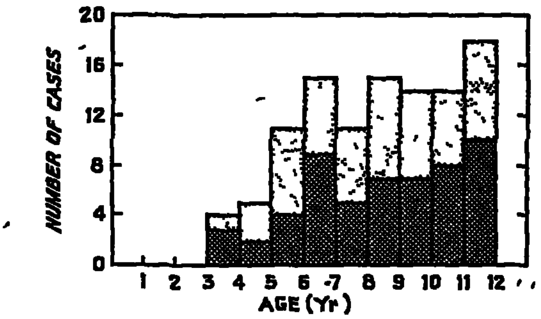

Fig 1—Age at onset of rheumatic fever and sex-distribution (*thatched*, boys, *stippled*, girls) of 107 cases surveyed

The distribution of cases by years of age at onset is shown in fig 1 The number of cases in children under the age of 5 is small—a usual finding

The frequency of antistreptolysin-O titres of 200 units or more per ml for the nine age-groups is shown in table I together with the geometric mean A S O, the frequency with which group A β hæmolytic streptococci were recovered at admission or within one week, and the frequency of preceding upper respiratory-tract infection within a month of onset of rheumatic symptoms (median period of 13 days)

Because the numbers in each of these nine age groups are small consecutive age-groups have been amalgamated into four groups for statistical analysis (table II) The four summed age-groups shown in table II show no significant differences in the frequency of upper respiratory infection and group A β-hæmolytic streptococcal isolations, but both the frequency of elevated A S O titres and the mean A S O titre is less in the younger children, particularly in the under-6 age group This is shown clearly in figs 2 and 3 This difference between the youngest age-group and the remainder is statistically significant ($\chi^2 = 12.6$, $n = 1$, $p < 0.001$)

TABLE II—DATA IN TABLE I REARRANGED UNDER FOUR SUMMED AGE GROUPS

—	Age (yr)				Total
	Under 6	6 to under 8	8 to under 10	10 to under 12	
No of cases	20	26	29	32	107
A S O titres No raised	9 (*45*%)	20 (*77*%)	25 (*86*%)	27 (*84*%)	81 (*76*%)
Mean (units per ml)	144	288	345	380	288
Upper resp infection (no of cases)	10 (*50*%)	16 (*61*%)	12 (*41*%)	18 (*56*%)	56 (*52*%)
Infection with group A β hæmolytic streptococci (no of cases)	9 (*45*%)	10 (*39*%)	15 (*52*%)	13 (*41*%)	47 (*44*%)

Discussion

We have not been able to detect any selection bias in the youngest age group, such as a more frequent administration of penicillin in the treatment of the preceding upper respiratory tract infection It would be desirable to examine a larger series in order to avoid summation in the younger age groups, but the frequency of attacks of acute rheumatic fever among children under 6 years of age is low, in the present seven year survey, only 20 such children were admitted to this unit who fulfilled the necessary criteria of diagnosis, activity, and age These children differed essentially from those in older age groups only in their lower antistreptolysin O level (fig 4) This is contrary to the earlier findings of Coburn and Pauli (1935), according to which A S O levels in rheumatic children showed, if anything, a tendency to lower levels with *increasing* age

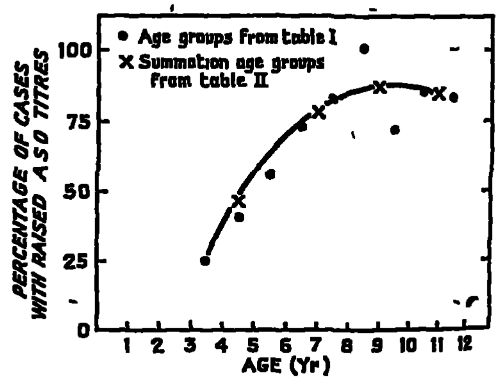

Fig 2—Age and percentage of cases with raised A S O titre (200 units or more per ml)

The present results show, then, that both the mean A S O level and the proportion of cases with raised titres are significantly lower in very young rheumatic children than in children over 5 years old These differences are also found, though not to a significant degree, in the 6–7 age group

We have also compared the levels with those in a small group of 40 children under the age of 12 years admitted to this unit with conditions unrelated to rheumatism (including 13 children under 6 years) In this group the mean A S O titre for those under 6 years was 49 units per ml (15% raised) and for those aged 6 years and more 105 units per ml (41% raised) It is therefore clear that in the youngest rheumatic group, although the titres are relatively diminished, the mean level of these titres and the frequency of raised titres are considerably higher than in non-rheumatic cases of a similar age in hospital We have not, however, had an opportunity of making a comparison with healthy children of various ages after β hæmolytic streptococcal infection

Powers and Boisvert (1944) have demonstrated an alteration in the natural history of streptococcal respiratory disease during the early years of life, the ill

TABLE I—RELATION OF AGE TO A S O LEVELS, PRECEDING UPPER-RESPIRATORY-TRACT INFECTION, AND RECOVERY OF GROUP-A β-HÆMOLYTIC STREPTOCOCCI

—	Age (yr)									Total
	3–	4–	5–	6–	7–	8–	9–	10–	11–	
No of cases	4	5	11	15	11	15	14	14	18	107
A S O titres No raised	1 (*25*%)	2 (*40*%)	6 (*55*%)	11 (*73*%)	9 (*82*%)	15 (*100*%)	10 (*71*%)	12 (*85*%)	15 (*83*%)	81 (*76*%)
Mean (units per ml)	89	112	199	282	295	380	300	372	380	288
Upper resp infection (no of cases)	2 (*50*%)	3 (*60*%)	5 (*45*%)	8 (*53*%)	8 (*73*%)	6 (*40*%)	6 (*43*%)	6 (*43*%)	12 (*66*%)	56 (*52*%)
Isolation of group A β hæmolytic streptococci (no of cases)	2 (*50*%)	2 (*40*%)	5 (*45*%)	5 (*33*%)	5 (*45*%)	9 (*60*%)	6 (*43*%)	6 (*43*%)	7 (*39*%)	47 (*44*%)

Dumbfounded, I was unable to detect—even on repeated re reading—the reverential awe usually accorded to pronouncements of the Royal College of Physicians—in the present instance unassisted, it seems, by any other earthly body

Since large sums of public money are involved I hope the publication of Professor Wyburn's letter may assist those who are attempting the heartbreaking task of opposing specialised interests in order to render the training of medical students "economic," and thus to produce a doctor confidently consulted when one is ill

Sheffield JOHN L EDWARDS

WHOLE-TIME SPECIALISTS

SIR,—I should like to say how much I approved of Dr Gilchrist's masterly résumé (April 14) of the situation that now confronts full time specialists—consultant and S H M O alike

The inequalities and injustices which he lists are unlikely ever to be righted until *adequate* representation for the non teaching full-time specialists is obtained on the Joint Consultants Committee (which is also in practice the staff side of Whitley B)

This committee is the only body that negotiates with the Ministry and the management side of Whitley B on behalf of the specialist services It is an autonomous body, and in particular it is not responsible to the Central Consultants and Specialists Committee There have been, in fact, occasions when the Joint Consultants Committee have altered documents or policies which have previously received approval in the regional and central consultants organisation (the Strachan report on hospital staffing is an outstanding example)

It is extremely difficult for the full-time consultant and S H M O to see why their reasonable request for adequate representation on the Joint Consultants Commiteee is resisted The reasons given are usually three.

(*a*) That it is a mistake to introduce sectional interests on to this committee

(*b*) That the full time specialists have opportunity through the regional machinery that finally produces 6 members of the Central Consultants and Specialists Committee on the Joint Consultants Committee to get their representatives elected

(*c*) That alteration of the present machinery would result in "splitting" of the profession

None of these "reasons" seems to me valid or even true The first, about sectional interests, begs the question entirely It is difficult to see what particular quality part-timers have that make them less likely to be partisan than the *full* timer The results of the past eight years' negotiations have been much to the advantage of one section—and that is the section that practically monopolises the representation

It is true that the full timers could obtain representatives by the regional machinery Their numbers are nearly equal to the part timers' and they would have the support of 1200 part-time S.H M O s whose interests march with theirs But this would mean a deliberate electoral campaign in the regions the displacing of many valuable men who are now representatives and ill feeling between the two sections At the end they would obtain a share of the 6 seats on the Central Consultants and Specialists Committee and would still be out numbered by the 11 representatives of the colleges This solution would indeed mean "splitting"

As to the third reason, I submit that the exact opposite is true It is the consistent discouragement and the refusal of his reasonable requests that will drive the full-timer to a split This seems more and more likely to happen

The solution would be to enlarge the Joint Consultants Commitee to 23 and give the 6 extra places to the full time specialists This would ensure that their viewpoint was adequately heard and at the same time correct the present overbearing representation of the colleges Such a committee would present a united front to the Ministry and represent the whole specialist services

As this graceful gesture by the Joint Consultants Committee seems highly unlikely, I support Dr Gilchrist's suggestion of a full-time specialist group We must get our representation the hard way

Derby G HOWELLS

ADRENALECTOMY FOR VASCULAR DISEASE OF DIABETES

SIR,—While I agree with much that Dr Malins says in his article last week, there are two points which, I think, require modification

In the first place he quotes me as saying, in a personal communication, that hypophysectomy may produce intractable hypoglycæmia My experience of this operation is limited to one case in which severe hypoglycæmia occurred after operation, but the fact that the patient is still alive and well one year later makes the word "intractable" inappropriate

Secondly, I cannot agree that there is sufficient justification for the statement that "it seems certain that retinopathy will develop in every diabetic who lives long enough, and that the final stage of blindness will arrive in those who do not succumb to renal failure before their sight fails" Both Dr R D Lawrence and I have seen a number of patients who have had diabetes for thirty years or more and are completely free from complications, I see no reason why these patients should develop either retinopathy or nephropathy Dr Joslin, of Boston, also has many such patients and indeed gives them a victory medal

There would seem to be a group of long-standing diabetics in whom such complications are absent or minimal, and, until more is known of the ætiology of the complications of diabetes, such a dogmatic statement as that made by Dr Malins seems to me to be unduly pessimistic

London W 1 WILFRID OAKLEY

PERFORATED ACUTE AND CHRONIC PEPTIC ULCER

SIR,—I read with interest the latest results of conservative therapy published by Mr Hermon Taylor and Mr R P Warren (April 14) and note that they confirm the fundamental difference in the prognosis of perforations in acute and in chronic ulcers to which I drew attention in presenting the results of primary suture in 1953[1]

In discussing the immediate-mortality rates they argue that there is little to choose between the two methods of treatment I must, however, correct their statement that my series of 206 perforations was "a selected group of operable cases," for this is a misconception My cases were the consecutive admissions of all the perforations which came into my wards on my receiving days during the period under review There was no selection, and although some were very ill none was refused the chance which operation offered The mortality of that series—6 3%—must therefore stand The records' officer at the Royal Victoria Infirmary tells me that during the past five years 942 patients with perforated peptic ulcers were admitted to the hospital of these, 41 died after operation (4 4%) and 20 were moribund on admission and died without operation (2 1%), giving a total mortality of 6 5% In 1955 the figures were even better there were 156 perforations, none of these patients was admitted moribund and 6 died, giving a total mortality of 3 8% for this series

Results of this kind amply justify the continued employment of laparotomy and primary suture as the local effect as well as to inhibition of the anterior lobe of the pituitary gland

---

Material

This paper is an analysis of 106 cases of breast cancer treated with either œstrogen or androgen in women who died in a period of seven years, and the following data relate to the patients' state when accepted for hormone therapy

All the patients had advanced stage IV cancer of the breast and had already received all possible benefit from either X-irradiation or surgery or both, or else the lesion was too far advanced for anything except palliative hormone therapy

Previous treatment—Of the 106 women 3 had had surgery alone, 10 X-irradiation alone, 82 surgery and irradiation, and 11 no treatment

Histology—78 patients had histologically proved carcinoma, but Broders's grading was not stated in many of the pathological reports Records of histology were missing in 7 There were no pathological reports in 21 cases which were much too advanced for surgery and in which the diagnosis was obvious on clinical findings

The *duration of disease* before the start of hormone treatment was as follows 94 5% of the women had had the cancer for 6 months, 86 0% for 1 year, 68 0% for 2 years, 48 0% for 3 years, 34 0% for 4 years, 21 0% for 5 years, 10 4% for 7 years, and 4 0% for 10–15 years

Connubiality—24 6% of the patients were single and 75 4% married

Age distribution—9 patients (8 5%) were aged less than 40, 61 (57 5%) were aged 41–60, and 36 (34%) were aged 61 or more

The menopause had occurred in 81%, and of these it had followed either irradiation or oophorectomy in 12 6%

Pregnancy or miscarriage was recorded in 55 6%

Distribution of metastases was as follows

Axillary, supraclavicular, or other lymph-nodes	74 5%
Skin nodules, ulceration, or infiltration	70 0%
Bones	52 8%
Lungs or pleura	33 0%
Other breast	21 7%
Other sites	14 3%

Some patients had metastases in several or all of these sites

General condition—Advanced cardiovascular disease was found in 8 5% The general nutrition was good in 37 8%, but 56 5% had lost weight up to 2 st and 5 7% more than that

Methods

All the patients were interviewed and examined monthly or every two months according to their condition and response to treatment Serial records of weight, hæmoglobin, erythrocyte sedimentation rate (E S R) (Westergren), and blood alkaline and acid phosphatase were kept Changes in lesions were recorded photographically or followed on serial radiographs

Œstrogen Therapy

Originally the British Empire Cancer Campaign wished to compare the effect of low dosage (0 3 mg q i d) with that of high dosage (5 mg q i d) of stilbœstrol Printed forms were received, and patients were allocated at random to the dosage printed on these, by this means no individual selection of high or low dosage was made by each investigator Patients were, if possible, kept on their allotted dosage until death A change to high dosage was made only if it was obvious that no effect was being obtained from low dosage Similarly, on occasions the dosage had to be lowered if symptoms of toxicity were intolerable

Much individual variation was noted in tolerance within the dosage range 0 3–5 0 mg q i d After preliminary nausea, anorexia, flatulence, or giddiness most patients became gradually tolerant, but a few remained unable to take stilbœstrol In my experience small doses of this hormone are practically valueless, hence early doses of 5 mg q i d are advocated, with increase of this amount to as much as 50 mg q i d if required

Although the œstrogen was usually stilbœstrol, occasionally ethinyl œstradiol was substituted because of intolerance or sometimes when large dosage was required

Androgen Therapy

57 patients were treated with androgens—of these, 6 were aged less than 40, 38 were aged 41–60, and 13 were aged 61 or more, 35 of these (61 4%) had bone secondaries when first seen

To determine whether androgen therapy was of benefit or not, it was decided to give the largest possible tolerated dosage and to maintain this until there was some clinical or radiographic improvement, or until it was obvious that the patient was rapidly deteriorating When this trial started, it was necessary to collect as many cases as possible for inclusion in the British Empire Cancer Campaign trial of low and high dosages of œstrogen, and some of the early cases were so treated although bone secondaries were present, when better judgment would have indicated treatment with androgens However, after some experience, the younger patients and those with osseous metastases were given only androgens

The high dosage chosen, 300 mg daily, was not limited at first by expense, because adequate material was freely available through the generosity of several firms

Most patients treated with androgens were given daily injections, but some, too thin to tolerate repeated treatment by this route, or to give them a brief rest, were given oral therapy with either methyl androstenediol or methyltestosterone A few were also treated with implants of testosterone or of testosterone propionate for various reasons—e g, difficulty of regular attendance and supervision

Large dosages of androgens were usually continued indefinitely, even when patients were in a quiescent stage in reasonable health, though often the frequency of dosage was lessened, only to be restored with signs of further deterioration or spread

For example, in a patient who survived for 260 weeks, the following enormous doses were given 60 7 g of testosterone propionate, 84 0 g of testosterone isobutyrate, 10·5 g of methyl androstenediol by injection and 8 4 g by mouth, and 6 72 g of methyltestosterone by mouth up to about a month before death

In the patients who had been menstruating until the start of treatment amenorrhœa persisted

Toxic Effects

Œstrogens

The well recognised toxic effects of stilbœstrol and ethinyl œstradiol are common even with minimal dosage for endocrine dyscrasias, but (as already stated) a much bigger dosage was believed to be necessary and was given Hence it is not surprising that 40 3% of the patients so treated complained of toxic effects It was necessary to encourage these patients to persevere with the prescribed dosage, and usually tolerance improved Some patients assimilated 160–200 mg of stilbœstrol daily

Toxic symptoms noted were anorexia, flatulence, nausea, retching, sometimes vomiting, dizziness, and general malaise These symptoms developed either early or late in treatment, in the latter case they were possibly due to hepatic metastases impairing detoxication Often these patients were lethargic, dehydrated, and wasted, with dry inelastic sallow skin

Androgens

Only 29 8% of the patients treated with androgen complained of nausea or vomiting Sometimes it was necessary to reduce the daily dosage, and potassium citrate and a powder of magnesium trisilicate and bismuth carbonate were of value In view of the suggestion that the toxic effect in the earlier cases in this series treated with massive therapy was due to hypercalcæmia, the ontribute as much to their therapeutic action as their nown effects on the thalamic structures It must be emembered that severe somatic pain may frequently be elieved by cortisone, and that the emotional upsets of he climacteric sometimes respond to œstrogens and/or ndrogens

Again, we have found that administration of meprobamate causes changes in fecal flora from a proteolytic to a saccharolytic type—a change to which the humoral effects of antibiotics have been ascribed [4, 5] and which have also been invoked to explain the dry-weight gain of domesticated non-ruminant animals ingesting them This explanation must be re examined in the light of a study at the Loblund Institute showing acceleration of growth-rate in germ free poultry fed antibiotics [6] Meanwhile an interesting common denominator underlying hormones, antibiotics, and tranquillisers seems to be emerging Patients on rauwolfia or meprobamate frequently show the voracious appetite and weight gain found in patients under treatment with antibiotics The mental effects of isoniazid [7] are now well known, and insomnia and enhanced psychomotor activity has been observed in some patients on long-term treatment with streptomyces derived antibiotics [8] It was in fact this complication of sustained antibiotic administration that led to routine administration of meprobamate in a series of patients with inoperable neoplastic disease to whom antibiotics were being administered [9], and this therapy has commonly modified the humoral effect of the antibiotic,[3] sometimes in the direction of enhancement

In acute experiments on unanæsthetised dogs, reserpine has been shown to augment hydrocortisone output of the adrenals [10], this effect is more intense and rapid on chlorpromazine administration (D M Hume personal communication) While the investigators who report this stipulate that no conclusions can necessarily be drawn regarding similar effects from clinical administration, we believe these to be forthcoming

MENOPAUSAL PANNICULOSIS

SIR,—Referring to your valuable annotation (April 21) on menopausal panniculosis, which as Dr Baker says is a much better name than panniculitis, the practical problem has always been to decide on the most suitable diet whether in fact the increased weight is partly due to water retention, or is entirely fatty The problem can be solved by recording the weight for several days, then making the patient drink an appropriate amount of an exchange resin A drop in weight indicates whether water retention is a factor and to what extent The exchange resins are, however, very unpleasant to take in water, and I am not satisfied that eating biscuits made of the stuff, though helpful in treatment, would give a clear cut indication of the trouble

Recently I have used acetazolamide ('Diamox'), giving 250–500 mg (according to the weight) to thirty patients, all with possible water retention As with the exchange resin, the weight is recorded daily for several days, on one of which the drug is taken first thing in the morning Patients with severe water retention will have lost as much as 4 lb by the next day, though 2–3 lb is the most usual On the other hand, no drop in weight denotes that retention of water in the tissues does not play a part in the panniculosis syndrome and the low-sodium diet usually prescribed is needless

Of the thirty cases, seventeen were positive to the test and were put on the Foldes [1] diet with acetazolamide 250 mg once a week

My thanks are due to Messrs Lederle for a supply of 'Diamox' tablets

H WARREN CROWE

TRANSPORTING PATIENTS WITH BULBAR OR RESPIRATORY PARALYSIS

SIR,—Dr Scott and Dr Knox (April 21) perform a valuable service in emphasising that patients with paralysis of swallowing or of respiration, or both, should be under medical supervision when they are transported to the hospital where they are to be treated They suggest, however, that patients with established paralysis of swallowing and slight respiratory involvement should have a tracheotomy before they are moved In our experience such patients can be moved easily and safely if a cuffed endotracheal tube is first passed under local anæsthesia The tracheotomy can then be done under good conditions on arrival at the final hospital, and the difficulties and danger of an emergency tracheotomy in a small hospital or in the patient's home are avoided

Unemployed Doctors

ON April 24 Dr DONALD JOHNSON reminded the House of Commons that 35 doctors are drawing unemployment benefit This figure he believed represented a much larger number who, for obvious professional reasons, were not attending the employment exchange, but were hanging about, either unemployed or under-employed, hoping for something to turn up It represented, too, a still larger number of doctors working as assistants in jobs without prospects It was not correct to say that these unemployed doctors were down-and-out and good-for-nothing Young men were qualifying and older men were returning from overseas, and they were unable to find places in the National Health Service It might be that more doctors were qualifying at present than were needed, but he suggested that the difficulty was really due to the falling-in of practices In the old days in every purchase and sale there was an agreement for goodwill to be handed on, and there was an incentive for the vendor, or the widow of a deceased doctor, to keep the practice together Now there was no incentive to do so A vendor gave notice and left, and the widow of a doctor who died suddenly had no particular interest in the practice and might create difficulties by holding on to the house It was left to executive councils to select a successor It was equally difficult for a doctor to establish himself in an under-doctored area He still needed money for a house, and with uncertain prospects he was not a good risk for anyone to advance money on mortgage In view of the ever-expanding need for medical attention in the country something should be done to make the fullest possible use of the medical man-power available

Miss PATRICIA HORNSBY-SMITH, parliamentary secretary to the Ministry of Health, felt that Dr Johnson had painted too gloomy a picture Medicine was an entirely independent profession and the Minister of Health was not responsible for ensuring that every doctor was employed. The profession would certainly fight to retain the liberty of choice as to the type of practice doctors might enter or the places where they should practise In the general-practitioner service most doctors were appointed by other doctors in partnerships A few

[1] Földes E New Approach to Dietetic Therapy Boston, Mass, 1933

These figures indicate that the prognosis in women aged more than 60 at onset was worse than in younger women 97 3% of the patients were still alive after 6 months from the onset of symptoms, 87 8% after 1 year, 62 2% after 2 years, 46 0% after 3 years, 34 0% after 4 years, 26 4% after 5 years, 5 6% after 10 years, and 2 8% after 15 years

Improvement was observed in 31 patients (29%) 1 aged less than 40, 19 aged 41–60, and 11 aged 61 or more In 13 of the 14 women treated with œstrogen the first symptom had started after the menopause Œstrogen therapy was started 4–27 years (mean 15 years) after the onset of the menopause 7 of these patients had not undergone operation, because the cancer was too advanced when they were first seen The average age of the 14 women was 63, and their average survival was 32 months a woman on 0 3 mg q i d survived 59 months with quiescent bone metastases, another on 0 3 mg q i d survived 29½ months with temporary regression of soft tissue metastases, a woman on 5 0 mg q i d or more survived 17 months with quiescent bone metastases, and 11 women on 5 0 mg q i d or more survived 31 7 months (mean) with good regression of soft-tissue metastases

Only 17 patients (30%) of those treated with androgens showed some improvement, their average age was 49 and average survival 17 25 months Of these 17 women 14 (82%) had their first symptom before the menopause (1 underwent hysterectomy 11 years before the first symptom), and 4 had had neither surgery nor radiotherapy The results of treatment were as follows

	No of patients
Skin deposits regressed	7
Lymph nodes regressed	6
Bone healing and recalcification	4
Abdominal secondaries regressed	2
Lung metastases regressed	2
Loss of pain and subjective improvement but no change in secondaries	3

The different types of metastases responded as follows

Type	*No of patients*	*No improved*	*With œstrogen*	*With androgen*
Skin	74	17	10	7
Lymph glands	79	13	7	6
Bone	55	4		4
Lungs and pleura	35	3	1	2

Of the 55 patients with bone metastases 35 were treated with androgens, and of 31 complaining of severe pain 11 were relieved, including the 4 showing improvement radiographically 6 patients had pathological fractures (4 during treatment) in which there had been no clinical improvement In one the fractures were present on starting androgen treatment and subsequently healed in another a fracture occurred during the early phase of treatment but later healed, together with radiographic improvement in the other bone metastases After œstrogen treatment none of the remaining 20 patients who had bone metastases showed clinical or radiographic improvement, and pathological fractures occurred in 4 during the course of therapy

In addition, less objective evidence of improvement was obtained by assessing the effect of treatment on the following

(1) Pain or distress, which occurred in 80 patients, 20 of whom obtained relief

(2) Serial hæmoglobin levels Before the start of treatment anæmia was found in 49 patients, 24 of whom had radiographically proved bone metastases There was virtually no improvement with treatment

(3) The E S R was raised initially in 68 patients and fell during treatment in 17

(4) The body weight increased in 23 (13 given androgen, 10 given œstrogen), decreased in 53, and did not change in 30

(5) Blood alkaline phosphatase no definite correlation was found between clinical improvement or extension or regression of bone metastases judged by radiographic appearances In one or two cases with bone secondaries which improved with testosterone where the initial pre treatment levels were high, subsequent values were much reduced On the other hand, some cases treated with œstrogen showed similar changes in phosphatase with progressive deterioration in osseous metastases

Discussion

A therapeutic trial of this kind can only help to assess the effect of alteration of the steroid hormone balance of the host and makes no allowance for the specific malignancy of the cancer Unfortunately the complete Broders's grading of each case was unknown In a few cases no details of the histology were available and many years had elapsed since the original operation

In the preliminary trials it soon became apparent that only the old postmenopausal women with soft tissue metastases might benefit

The survival of any one patient with breast cancer of this advanced stage of severity must obviously depend on numerous factors—the patient's age, the distribution and type of metastases, the grade of malignancy, the hormone dependence (whether of œstrogens or possibly of pituitary hormone), and other general health factors

Spontaneous regression has been reported by Gordon Taylor, but malignancy may lie dormant for years In the present series, however, the 106 patients had very advanced stage IV metastases Even so, some patients were in reasonable general condition, whereas others were almost moribund No cases were selected except that those with clinical evidence of considerable liver metastases were excluded

Comparison is necessary with the survival of patients with untreated advanced mammary cancer

Wade (1946) reported 27 untreated patients with breast cancer of whom 24 were in stage III The average duration of life was 8 months from first being seen, and all were dead in 2 years

Greenwood (1926) found a mean survival of 38 3 months from the onset of symptoms in 651 cases, Wyard (1925) found the mean duration of life to be 37 months in 311 cases, and Daland (1927) quotes 40 5 months in 100 cases Wade has collected these numbers together and found that the average duration of life in untreated cases was 38 55 months in 777 patients, and that the duration of life increased from the age group 25–34 to that of 65–74 and then decreased again

According to Wade (1946) X irradiation alone or together with surgery raised the survival time by 21 5% at one year, 22 5% at 2 years, 10% at 3 years, 10 5% at 4 years, and 9 5% at 5 years over the survival rates of untreated cases In her series the mean survival of 27 patients with advanced stage III untreated cancer when first seen was only 8 months, hence 12 months' survival in the present series of advanced stage IV cancer after treatment with hormones is possibly significant All her patients had died in 2 years, whereas 11 6% of the present series were alive at 2 years and 4 7% at 4 years

As regards surgical treatment alone, Lewison et al (1953) claim a 5-year survival rate of 43 2%, regardless of the type of operation These were presumably selected cases, inoperable stage IV cancer being almost certainly excluded

In the present series most of the patients had received standard surgical and X ray treatment in addition to hormones, and the mean duration of life was 58 5 months from the first symptom There was a 5 year survival rate of 26 4% from onset Although superficially this compares unfavourably, it must be remembered that my series consists solely of stage IV advanced cancer

The age at onset seems to influence duration of life In patients who developed cancer of the breast when over 60 the percentage expected survival in 5 years was 20% less than in patients aged less than 40, and 30% less than in patients aged 41–60 A similar prognosis was reported by Burdick and Chamatry (1954)

In the present series of advanced stage IV cancer the percentage expectancy of life in 5 years was significantly greater after hormone treatment in the patients aged

Obituary

ALAN SEYMOUR PHILPS

F R C S

Mr Seymour Philps, surgeon in charge of the eye department of St Bartholomew's Hospital, died at his home in London on April 26, at the age of 50

He was the son of John Philps, a former editor of the *Financial Times*, and he was educated at Aldenham School and St Bartholomew's Hospital After qualifying in 1929 he became house-surgeon at Barts to the late George Gask He took the F R C S in 1931 For a time he worked on the staff of London Passenger Transport Board, but he was already interested in ophthalmology and after holding house-appointments at the Royal Westminster Eye Hospital he became in 1932 out-patient officer at Moorfields Later he returned to Barts as registrar in the eye department and he also joined the staffs of the Victoria Hospital for Children, the Miller General Hospital, and the Royal Westminster Eye Hospital In 1934 he became chief assistant in the eye department at Barts and in 1940 a full surgeon at Moorfields

[Lafayette

During the late war he was an adviser in ophthalmology to the War Office and as an ophthalmic specialist in the R A M C he took part in the Normandy landings "My chief impression of that time (he later wrote in our peripatetic columns[1]) is feeling 'This is none of I,' as one did things no middle-aged oculist ought to do, such as wade through the French surf at dawn in charge of a section of 12 men"

In a D+3 battle dress, in which stains of blood, oil, and flavine fought for the upper hand, he paid a flying visit to liberated Paris before setting off to convoy 20 trucks across France to Belgium "This ignorant oculist (he relates), more used to removing fragments from the cornea than convoying three ton trucks, had imagined that anything as big as a lorry would be difficult to lose, but the trouble was to find any of them We made bad time, and still had 100 miles to go on the last day, but when we started at dawn someone had chalked on the front truck, BRUSSELS OR BUST, and that was how we all felt"

Back in the quieter atmosphere of Harley Street and Charterhouse Square, he settled down to the more orthodox aspects of ophthalmology, and in 1948 he was appointed surgeon in charge of the eye department at Barts In 1949 he also renewed an early interest when he became adviser in ophthalmology to the Ministry of Transport In 1950 he published his *Ophthalmic Operations*, beautifully illustrated with his own drawings and photographs

G B writes "Ophthalmology's attraction for Philps was a logical result of his personality He was fascinated by the delicate, the intricate, and the precise He was a first-rate cabinet-maker, and a magnificent draughtsman of tiny and delicate subjects The accuracy and beauty of his water-colour drawings of the fundus of the eye were only equalled by the precision and neatness of his surgery on that organ A brilliant operator and careful clinician, he was also a clear and good teacher, and his organising powers equalled his other talents

"As a medical student he was called 'Streak,' and this name stuck to him He was always thin in build, but in the nickname there was also an appropriate connotation of speed and lightning brilliance of mind, speech, and body His death at the age of 50 is cruelly premature He had potentially so rich a store of personal and professional qualities as yet unexpended His reputation was already international, and friends in Australia, the United States, and the European countries will lament the passing of a sparkling friend and a fine colleague His book on *Ophthalmic Operations* stands as a record of his achievement, but the memory of his personality, so richly endowed with flashing humour and with great gifts of sympathy and kindness will live in the hearts of his friends when operative techniques have been modified or superseded

"Not the least is Philps's memory linked with the virtue of great courage Two years before he died he knew that he suffered from a mortal illness But this caused neither weakening of his purpose, nor the reaction of bravado He remained his poised, sincere, cheerful self until his last hour He leaves a wife, to whom he owed much, and five children"

Medicine and the Law

Procedure of the Medical Disciplinary Committee

Dr Ong Bak Hin, of Malaya, appealed to Her Majesty in Council from a determination of the Medical Disciplinary Committee on Nov 25, 1955[1] The formal charge before the committee alleged that in 1953 he had been convicted in the High Court of Malacca of having unlawfully performed an operation of abortion which caused the death of the patient The committee adjudged the appellant guilty of infamous conduct in a professional respect and directed the registrar to erase his name from the Register

Lord TUCKER, giving the judgment of the Judicial Committee of the Privy Council (Lord Oaksey, Lord Tucker, Lord Cohen, Lord Keith of Avonholm, and Mr L M D de Silva), said that at the inquiry the appellant's solicitor submitted at the outset that justice could not be done to his client unless the witnesses who had given evidence at his trial were called to give oral evidence before the committee The legal assessor pointed out that the committee had no power to compel the attendance of witnesses from Malaya and advised the committee to proceed on the documentary evidence The solicitors on each side drew the attention of the committee to such portions of the evidence as they considered relevant, but it was agreed that the committee should be at liberty to look at any parts they wished It was contended before their Lordships by counsel for the appellant that the proceedings at the inquiry were defective and not strictly in accordance with the rules of procedure which governed the committee and that the determination should be set aside He further submitted that if the notes of evidence were received they should all have been read out before the committee and that failing that the committee should have read the entire evidence themselves which, he said, they could not have done in the time available having regard to the length of the hearing

His Lordship then referred to relevant sections of the Medical Acts of 1858 and 1950 and to the Medical Disciplinary Committee (Procedure) Rules, 1951, made under the latter Act, and to rule 63 thereof which provided

> 'The Committee may receive any such oral or other evidence as would be receivable in a Court of law, and in addition may after consultation with the Assessor to the Committee, treat any statement of fact contained in any document as evidence of that fact"

The position of the General Medical Council in relation to its disciplinary powers under the Medical Act of 1858 was considered by the House of Lords in General Medical Council *v* Spackman ([1943] A C 627) The

SERUM-CHOLINESTERASE LEVELS IN DIABETES MELLITUS

R H S THOMPSON
M A , D M , B Sc Oxfd
PROFESSOR OF CHEMICAL PATHOLOGY

J R TROUNCE
M D Lond , M R C P
ASSISTANT IN THE DEPARTMENT OF MEDICINE

GUY'S HOSPITAL MEDICAL SCHOOL, LONDON

In 1937 Antopol et al briefly reported that the plasma cholinesterase level was raised in diabetes mellitus—an observation which was confirmed by Faber (1943) and by Cristol et al (1946) Each of these reports, however, described only a small series of diabetic patients, and no details were given of the age of the patients, or the type or severity of the diabetes

Saviano et al (1948) reported raised plasma cholinesterase levels in dogs with alloxan diabetes Berry et al (1954), however, found a strong correlation between the amount of surface fat and the plasma cholinesterase level in a group of 345 men from three districts in England, and suggested that the high cholinesterase values found in diabetes mellitus might be related, not to the diabetic state per se, but to the obesity which often accompanies it

We therefore determined the serum cholinesterase levels in a series of diabetic patients and recorded whether these patients were "obese" or "non obese" The severity of the diabetes and the adequacy of the control by insulin were assessed Serum-cholinesterase levels were also determined in a series of obese non diabetic patients attending hospital for other reasons

Method

Blood was drawn from the antecubital veins of 50 adult patients with diabetes mellitus (25 of them obese and 25 non-obese), 25 adult obese non diabetic patients, and 33 non-obese healthy adults

In most cases, blood was taken in the afternoon , a study of 2 healthy subjects showed that there was no significant difference between the fasting serum cholinesterase level and the levels at one, two, three, and four hours after a meal containing 60 g of fat

The diabetics were all outpatients under treatment, and the diagnosis had been confirmed by blood sugar estimations The degree of control of the diabetes was assessed by the amount of glycosuria, determined by daily urine-testing (' Clinitest ') and interpreted as follows

Degree of control	*Results of urine tests*
Good	Never more than blue or green throughout the twenty four hours
Fair	Usually green, occasionally tan colour
Bad	Frequently tan colour

The severity of the diabetes was assessed by the dose of insulin required to establish control, but we realised that this was only a very limited method of assessment

The presence of obesity was established on clinical grounds, bearing in mind the patient's height, weight, build, and amount of subcutaneous fat

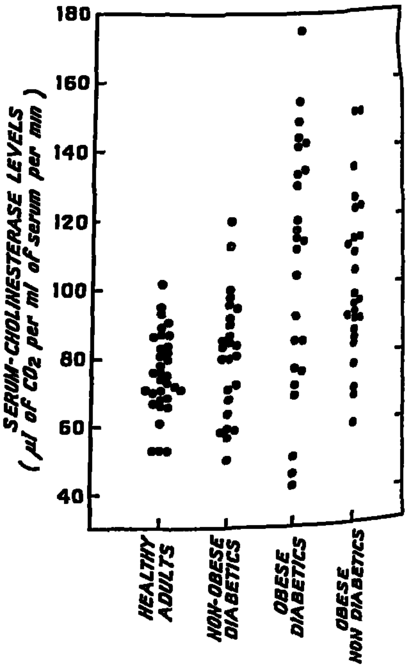
As it was not our aim to discover a precise correlation between plasma cholinesterase levels and small variations in the degree of obesity, we decided that this classification was adequate for the purpose of the investigation, and we did not attempt a more accurate assessment of the amount of subcutaneous fat, such as measuring the thickness of the subcutaneous tissue fold (Edwards 1950)

All but 4 of the obese non diabetic patients were attending hospital on account of their obesity In the remaining 4, the obesity was coincidental

Estimation of Cholinesterase

Cholinesterase activity was estimated manometrically on a sample of the separated serum by a modification of the method of Ammon (1933)

The free acid released from the choline ester by the action of the cholinesterase liberates carbon dioxide from the 0 025 *M* sodium bicarbonate medium, acetylcholine perchlorate (0 015 *M*) was used as substrate Measurements were done in duplicate and were corrected for non enzymic hydrolysis of the substrate These enzyme measurements were made by one of us (R H S T), who at the time was unaware of the patient's clinical state, but in every case serum either from a healthy person or from a non obese diabetic, and serum from an obese diabetic or an obese non diabetic patient, were assayed simultaneously Cholinesterase activity was expressed as µl of carbon dioxide per ml of serum per minute



Serum cholinesterase levels in four groups of adults

Results

The serum cholinesterase levels found in these 4 groups of subjects are shown in the accompanying figure, and the mean values and the standard errors of the mean are listed in the accompanying table The levels in the healthy adults varied from 53 to 102 µl of carbon dioxide per ml of serum per minute Of the 25 obese

Notes and News

RESEARCH ON RHEUMATISM

On Tuesday, with the Duke of Gloucester presiding, the Empire Rheumatism Council received its 19th annual report from Dr W S C Copeman, who in 1953 succeeded Lord Horder as chairman

Describing the council as "pre eminently a research organisation although it in no wise neglects the subjects of teaching and treatment," Dr Copeman said that its laboratory, at the Hospital of St John and St Elizabeth, is being used by Miss H Muir, D PHIL, an E R C fellow working mainly on connective tissue polysaccharides at St Mary's Hospital Another E R C fellow, of long standing, is Mr J K Norymberski, D ING, director of medical research in the Sheffield centre, who is further investigating steroid hormones, and a third, Dr Madeline Keech, appointed last October, is studying denaturation of collagen and elastin with a view to analysing changes in connective tissue associated with disease A fund provided by the Geigy Pharmaceutical Company has enabled the council to send Dr Malcolm Thompson, Dr J Sharp, and Dr J Ball to work in the U S A, and a further Geigy travelling fellowship, for the same purpose, has been given to Dr E J Holborow The council is supporting steroid research by Dr J D Robertson and Dr L Chapman at the West London Hospital, a study of rheumatoid arthritis in two contrasting communities by Dr E Wittkower at McGill University, and investigations at Taplow by Mr H M Bassiouni, PH D, on the estimation of heparin like substances in blood tissues and by Dr S C Milazzo on antigenic substances in reticulin fibres and basement membranes A number of grants for apparatus have also been made

Turning to future plans, Dr Copeman spoke of a unit which is to undertake field research into rheumatic diseases Though probably based at first on Manchester University, it may eventually make investigations anywhere, including possibly the Dominions Dr J S Lawrence, the newly appointed medical director, will shortly be visiting other centres here and abroad where field studies of rheumatic diseases are in progress, and in due course a clinical, statistical, and radiological team will be assembled Dr E R Hargreaves, deputy M O H for Cornwall, has offered to do some additional preliminary survey work in that county, and Dr G R Fearnley's scheme for a parallel survey in Gloucestershire will be included Another survey conformative with the general one is to be made in Wensleydale by Prof C L Oakley, of Leeds

The Rheumatoid Arthritis Handbook prepared by the council for doctors to issue to their patients, has been "an unqualified success," nearly 20,000 copies having been distributed free of charge An Osteo arthritis Handbook is now in preparation

Supplements to this report are Dr Copeman's account of his official tour in Australia and New Zealand last autumn, and a description of the University of Manchester's rheumatism research centre directed by Prof J H Kellgren, whose chair was established by the council Also attached is a report from the finance committee expressing thanks but pointing earnestly to the need for new supporters The council's address is Tavistock House North, Tavistock Square, London, W C 1

B.M S A SYMPOSIUM ON MEDICAL EDUCATION

The British Medical Students' Association has been asked by the General Medical Council for its views on the medical curriculum An educational subcommittee is now investigating the 1st M B course and a report is being prepared To stimulate greater interest in the subject among students and to further the exchange of views between schools and between teachers and students, the London region of the association held, on April 21 at the London Hospital Medical College, a symposium on medical education Dr H B May, dean of the London, welcomed the participants, and the chairman, Dr R D Lawrence, of King's, opened the symposium The first speaker, Dr John Ellis, described medical education up to 1935 and the developments since that date Later, students from several London hospitals read papers on various aspects of present day medical teaching They all criticised the demands of examiners but most showed that their schools were doing the best that could be done for them under the present system

Dr G O Barber pleaded for the integration of the profession and asked that students, particularly the future consultants, should learn in their student days the importance of the general practitioner in the care of the community Prof Clifford Wilson emphasised that medical education should be a training in method not the acquisition of almost every available fact He outlined a medical course which seemed much better suited to fulfil this purpose

In a session on the teaching of specific subjects, Prof Ruth Bowden showed how, when teaching anatomy, she tried to persuade her students to study the body as a functioning whole, not as dissectable parts Prof G Payling Wright illustrated how the important diseases of one decade may not be the important ones of the next He thought that a full understanding of pathological processes was more useful than a vast knowledge of present histological appearances

In his closing remarks, Dr Lawrence drew attention to the problem continually facing medical students—what *can* they say and what *are* they to say when asked for information by patients? What had impressed him most during the symposium was the amount of thought which student speakers had given to their education and the way in which they had presented their views

BRITISH ASSOCIATION OF PHYSICAL MEDICINE

At this society's annual meeting, held in London on April 27 and 28, the following officers were elected president, Dr Philippe Bauwens, *vice president*, Dr Hugh Burt, hon secretary, Dr G O Storey, hon treasurer, Dr Donald Wilson, hon editor, Dr A C Boyle

At the annual dinner, on April 27, the toast of The Association was proposed by Dr W S Tegner, who remarked that this was the first meeting since the death of Lord Horder, the first president He forecast that the association would continue to flourish, citing as evidence the quality of the papers presented at the meeting Sir Harold Boldero replied for The Guests to a toast by Dr W A Fell, who likened the proposer of such a toast to a guide taking visitors round a zoo But his later remarks made it clear that those present had human interests

BRITISH STANDARD FOR SPECTACLE LENSES

A new standard for spectacle lenses (B S 2738) emphasises that "the criterion of success in a pair of spectacles is the comfort of the wearer" and points out that accuracy of lens preparation is essential to this end

> This standard includes requirements for definition of lens power tolerances on power of lenses cylinder axes centration of uncut lenses, optical centration of finished lenses, base apex direction, and powers of plano prisms, and the transmission characteristics of tinted lenses The standard calls for the glass or plastics used in lenses to be essentially free of such defects as bubbles, veins and other irregularities, and for lens surfaces to be well polished and free from waves, chips, and scratches Also specified are essential features relating to glazing and, for round spectacles, the marking of right and left lenses

Copies of this standard (price 3s) can be obtained from the British Standards Institution, Sales Branch, 2, Park Street, London, W 1

University of London

Dr A S Prophet, lecturer in dental surgery in the Queen's University, Belfast, has been appointed to the chair of dental surgery at University College Hospital Medical School

University of Bristol

On July 3 the hon degree of D SC will be conferred on Prof J Z Young, F R S, and the hon degree of M D on Dr J H Sheldon

University of Glasgow

On April 28 the following degrees were conferred

M D—M T D Braide J M White (with commendation)
Ph.D—S C Frazer

Royal College of Surgeons of England

On April 23 Sir Winston Churchill visited the college and signed the roll on his formal admission as an honorary fellow

Royal Society

At the invitation of the Academy of Sciences of the U S S.R this society is sending a delegation to Moscow, under the auspices of the *Soviet Relations Committee* of the British Council, to visit scientific institutions Lord Adrian, O.M, the immediate past president of the society will lead the delegation, and the other medical member is Prof J H Gaddum

to Dr C L Joiner for clinical help, and to Mr P G Hunt and Mr D E Jarvis for their skilled technical assistance

PERIARTERITIS NODOSA

ITS RELATIONSHIP TO ENDOMYOCARDIAL SCLEROSIS

J WATT
M B Aberd
LECTURER

J B LYNCH
M B Lpool, F R C S
LECTURER

DEPARTMENT OF PATHOLOGY, LIVERPOOL UNIVERSITY

IN periarteritis nodosa the heart is often involved, being second only to the kidney as the commonest organ affected Thus, Arkin (1930) states that it is affected in 70% of cases, and Harris et al (1939), from an analysis of the post mortem findings in 87 cases of periarteritis nodosa, give a figure of 84% In the varied clinical picture there are often symptoms and signs of cardiac disorder (tachycardia, dyspnœa, and œdema) and not uncommonly the end of the disease is congestive failure

Recently, cases presenting clinically as congestive cardiac failure of obscure origin have been described in which the principal finding at necropsy is a sclerosis of the endocardium and subjacent myocardium Several large series have been reported from Africa (Bedford and Konstam 1946, Ball et al 1954) Indeed, Davies and Ball (1955) state that endomyocardial fibrosis in their experience is the second commonest cause of heart failure in adult Africans The condition outside Africa is rare and, in the main, only isolated case reports have appeared A similar, though probably distinct, morphological picture is also seen in infancy First described as fœtal endocarditis, it is now most generally known as fibroelastosis of the endocardium (Weinberg and Himmelfarb 1943)

The interest of the following case lies in the occurrence of periarteritis nodosa in a boy aged 12 in whom endomyocardial sclerosis was a cardinal post mortem feature

Case-report

A boy aged 12 had mid abdominal pain on the evening of July 3 1955 He was seen by his general practitioner who prescribed a mild laxative On the following morning, his parents were shocked to find him dead

He was the fifth of ten children, and weighed 9^1 . lb at birth During the pregnancy, there had been no maternal illnesses and in particular no history of rubella, influenza or bronchitis At 1 year he was inoculated against diphtheria and re inoculated at the age of 9 but received no vaccination against smallpox During the first two years of life he h several attacks of bronchitis At 3 years he had pneumo and was treated in hospital with sulphonamides At 4 to years he had measles, whooping cough, and mumps, and one occasion was treated for threadworm infestation H development was normal until the age of 3, thereafter grow was retarded and at 12 years he was the same height as h 6 year old twin sisters—i e, 3 ft $9^1/_2$ in (average height 12 years is approximately 5 feet) He had a bright ale mentality, and led a normal active life, with full participati in games at school and never had any symptoms or signs *heart disease There was no history of rheumatic fev* asthma, or skin disease

On March 18, 1955, he was admitted to hospital becau he had had pain in the region of the left loin for 24 hou This was accompanied by dysuria He was toxic, the tong was heavily coated, and the temperature was 100 F Oth wise physical examination was negative In particular th was no swelling or tenderness in the left loin, and the kidne were not palpable Intravenous pyelography and cystograp showed no abnormality apart from bifid pelves A ch radiograph showed no evidence of any focal lung lesion b there was a doubtful increase in the transverse diameter of t heart The urine was normal A presumptive diagnosis of left perinephric abscess was made and he was treated wi penicillin 250,000 units and streptomycin 250 mg, both s hourly Progress was satisfactory, and he was discharg from hospital on April 12, 1955 Subsequently he led a norm life without further symptoms until his sudden death in Jul

MAN'S CHOICE OF FOOD *

JOHN YUDKIN
M.A., Ph.D., M.D. Camb., M.R.C.P., F.R.I.C.
PROFESSOR OF NUTRITION IN THE UNIVERSITY OF LONDON,
AT QUEEN ELIZABETH COLLEGE

ANIMALS in their normal surroundings choose nutritionally adequate diets. Man too, in a wide variety of environments, often seems to do the same. We are usually content to assume that this demonstrates the existence of a food instinct. We can all think of apparent examples of this: the cattle that seek out salt licks containing mineral elements which their bodies need; the pregnant woman who demands fruit presumably because she would otherwise go short of vitamin C; the small child who eats plaster from the wall because he needs calcium. But when we look a little closer, we find that our interpretation of these events is very much coloured by our own emotions, by our tendency to evoke esoteric and mysterious reasons for matters which are not yet clearly understood. The pregnant woman may well demand not oranges but peaches out of season; the child may choose to eat boot-polish rather than the plaster, but it is not really likely that he now has a physiological demand for turpentine and wax rather than for calcium.

Looking still closer at the problem of food choice, we soon discover that it is determined by a great number of factors. Moreover, many of these are interrelated, so it is quite unrealistic to discuss in isolation the rôle of instinct in food selection.

We had better begin by realising that choice can be at quite different levels. At one level the choice may be between meat or vegetables, at another level between a cereal and a pulse or between meat and fish; at a third level between beef and mutton, or between rice and wheat; at a fourth level between Cheddar cheese and Cheshire cheese or between white bread and brown, or between fresh peas and canned. When we speak, therefore, of man's choice of food, we must make clear whether we are talking of a choice between, say, a meat diet and a vegetarian diet, or of a choice between ice cream made by one firm and that made by another.

The factors which determine choice may roughly be classified into three groups: physical, social, and physiological:

Factors of availability.—Geography. Season. Economics. Other factors: food technology, fuel.

Social factors.—Religion and social custom. Social class. Education in nutrition and hygiene. Advertising. Other social factors.

Physiological factors.—Heredity. Allergy. Therapeutic diets. Acceptability. Nutritional need.

Physical Factors

Geography

There is an understandable tendency to eat foods which are at hand. Geography has largely determined the very different diets of the Western European, of the Eskimo, and of the Chinese peasant. Even relatively small distances may make great differences to the diets consumed. In different parts of Nigeria, the staple food is either millet or cassava or rice. Nearer home, the Scots eat much more cakes, pastries, and biscuits, and much less fruit, green vegetables, and bacon, than the English (Domestic Food Consumption and Expenditure, 1953 [1955]).

The influence of geography has been greatly modified by the great improvements of transport during the last hundred to two hundred years. Before the 19th century there were great differences in diet even within England: in the south it consisted mostly of bread and cheese, with a little meat and bacon; in the north it was mostly oatmeal and milk. Only the large ports like London had access to the small amounts of imported foods.

This country in particular owes a great deal to modern communications for overcoming the dietary restriction imposed by geographical availability. Half of our food comes from overseas, both to supplement what we already grow (wheat, apples, cauliflower, potatoes, meat) and to give us foods we do not ourselves grow (vegetable fats, citrus fruits, tea, coffee, rice). Our choice of diet would indeed be restricted without modern means of transport.

Season

In many countries some foods are available only at certain seasons. Up to two or three centuries ago, this was also true to a large extent in this country. The winter diet of Britain was chiefly bread and salt pork; milk, cheese, and eggs were not easily available since it was not known how to maintain livestock adequately through the winter. It is often still true that the fruits of the earth are available only in their season. But in the industrially advanced countries the situation has now changed appreciably because of the improvement both in transport and in the methods of food preservation—canning, freezing, drying.

Economics

The rôle of economic factors is evident from study of the diets of different countries, or within one country from study of the diets of people of different degrees of wealth. Foods containing chiefly carbohydrate are on the whole cheaper than those containing chiefly protein or fat, and foods nutritionally less desirable cheaper than those nutritionally more desirable. With an increase in national income the intake of protein and fat increases, whilst that of carbohydrate stays fairly constant (table I).

TABLE I—RELATION BETWEEN NATIONAL INCOME AND DIET

Average annual income ($)	No. of countries	Average daily intake					
		Calories	Protein (g.)	Animal protein (g.)	Fat (g.)	Carbohydrate (g.)	Sugar (g.)
Less than 100	4	1860	48	11	34	345	42
100–200	9	2310	68	16	43	412	44
200–300	3	2590	77	27	68	416	63
300–400	4	2740	81	45	93	396	90
400–600	5	3070	92	46	112	424	84
Over 600	8	3210	95	58	129	416	122

Data compiled from Food Balance Sheets (Food and Agriculture Organisation, Rome, 1955) and from *Statistics of National Income and Expenditure* (Statistical Office, United Nations, New York, 1955).

There is also incidentally an increase in the consumption of sugar, implying a decrease in the consumption of other carbohydrate-rich foods like cereals and tubers—a fact to which I shall refer later. In any one country there is a similar dependence of the composition of the diet on income. In Britain these differences still exist, showing themselves chiefly as a decreased consumption of the more expensive and more nutritious foods with an increase in the size of family (table II). The amount of money available for food may be affected by a variety of factors. M'Gonigle and Kirby (1936) showed that the transference of people from slums to new houses, with higher rents, reduced the nutritive value of the diets. Tobacco and drinks may also be a prior call on income before food is bought. And in Peru and Bolivia the chewing of coca leaves by the chronically undernourished Indian, primarily to relieve hunger, leads to an even greater degree of malnutrition since the purchase of coca leaves reduces still further the amount of money left for food (Verzár 1955).

Under the heading of economic factors affecting food choice I include impositions by the State, such as first is the boy's age Most of those who have studied this subject think that congenital fibroelastosis is a disease of infancy and that it is a separate and distinct entity from the condition of adults which presents a similar macroscopic appearance Nevertheless, congenital fibroelastosis has been described in children at 6 and 11 years of age (Dennis et al 1953), and Thomas et al (1954), reporting cases at varying ages up to 70, thought that congenital fibroelastosis may persist into adult life The second discrepancy is the distribution of the endomyocardial sclerosis In particular, in this case the endomyocardium of the interventricular septum below the aortic valve was normal Thirdly, the degree of fibroelastosis of the endocardium was rather less than that is usually seen in the congenital type, and in contrast, the myocardial fibrosis was much more striking in the subendocardial region Therefore, despite the similarity of the morphological appearances, we do not consider this case to be one of congenital fibroelastosis persisting into late childhood

---

* Inaugural lecture delivered on appointment to the new chair of nutrition in the University of London.

In endomyocardial fibrosis as described in adult Africans, the lesion is a gross one with the endocardium showing varying grades of thickening of 3 or 4 mm , or even more, in depth, with definite subjacent myocardial fibrosis Of particular interest are those cases in adults outside Africa which have been described by various authors, including Loeffler (1936), Comeau (1937), Becker et al (1953), and Thomas et al (1954) The degree of endomyocardial sclerosis in these cases was variable, but in general it was intermediate between the congenital and African groups The case we describe is in our opinion an early example of endomyocardial sclerosis of this type The age of the patient, and the lack of any symptoms or signs referable to a cardiac disorder would accord with an early lesion

Macroscopically the heart in periarteritis nodosa may show the characteristic picture of aneurysmal dilatations of the coronary arteries, often described as "beading" In the absence of this finding there are no specific naked-eye features either in the myocardium or in the mural endocardium There is commonly some hypertrophy of one or both ventricles, usually the left The appearances on section of the myocardium are usually normal, but varying degrees of myocardial damage from acute necrosis to fibrosis, diffuse or focal in distribution, may be seen We have not found, however, any macroscopic description corresponding to the picture in this boy, where the myocardial damage showed a striking localisation to the subendocardial zone Histologically, in periarteritis nodosa, the only characteristic findings are the typical vascular lesions, and in their absence the picture is a non-specific one, such as is found in "isolated myocarditis" whatever the cause The myocardium shows diffuse or circumscribed lesions mainly of the interstitial tissues but also affecting the muscle-fibres There is no characteristic predominant cell type, lymphocytes, polymorphonuclear leucocytes, and eosinophils being found on occasion All transitions from acute inflammatory cellular exudate and necrosis to scar tissue formation are found even in the same heart This variable appearance is exemplified in the case we record here

From the standpoint of pathogenesis, the case has some bearing upon the problem of endomyocardial fibrosis It is beyond the scope of this article to review the various hypotheses of ætiology in adult endomyocardial fibrosis—malnutrition (Gillanders 1951), vitamin-B deficiency (Smith and Furth 1943), an allergic phenomenon (Loeffler 1936), or a collagenosis (Hill and Reilly 1951, Becker et al 1953)

Loeffler (1936), under the title "endocarditis parietalis fibroplastica with eosinophilia," described a case in which sclerosis of the endocardium with overlying thrombus was the chief pathological finding in a patient who died in congestive cardiac failure Since then several authors have reported single cases (Mumme 1940, Büchler 1941 42, Egger 1944, and others) A possible early case, the first in the British literature, was described by Lennox (1948) What was considered to be the first case in the American literature was recently reported by Hoffman et al (1955) This syndrome of parietal endocarditis with eosinophilia is considered by Loeffler to have an allergic basis Lennox (1948) points out that in favour of this theory his case was one of status asthmaticus, Büchler's case had a severe urticarial skin rash, and Egger's rheumatoid arthritis, and all had an eosinophilia In a case of this syndrome described by Roulet (1944), there were lesions suggestive of an allergic polyarteritis in the splenic arterioles and venules

In current opinion, periarteritis nodosa is probably an allergic or hyperergic response to some infection or toxic agent The occurrence of early endomyocardial sclerosis in association with periarteritis nodosa of the splanchnic vessels is of interest, not only for its rarity, but also for the support it lends to Loeffler's hypothesis

Summary

The association of endomyocardial sclerosis and periarteritis nodosa is reported, and the pathogenic significance briefly discussed in relation to Loeffler's "endocarditis parietalis fibroplastica"

We thank Mr F Beckwith, of the Pathology Department University of Liverpool, for the photographs

EPIDEMIOLOGY OF HYPEREMESIS GRAVIDARUM

J P B Fitzgerald
B Med Sc , M B N Z , M R C O G
LATE REGISTRAR, ABERDEEN MATERNITY HOSPITAL

MANY obstetricians consider that hyperemesis gravidarum was less common and less severe during the years of the 1939–45 war, but this impression has not been confirmed statistically Such a change in incidence and severity might help to confirm the clinical impression that psychological factors are important in the ætiology of this condition, and I therefore studied hyperemesis gravidarum in North east Scotland in the years 1938–53

Material

Between 1938 and 1953 674 patients with vomiting were admitted to the Aberdeen Maternity Hospital as booked cases or emergencies 453 showed the characteristic picture of hyperemesis gravidarum, 91 had late vomiting of pregnancy of unknown origin, and in 130 the vomiting was associated with the conditions listed in table I urinary tract infections being the most common their original non-nutritional classification of good and bad foods, but now attribute these different qualities to the presence or absence of vitamins. They have also decided that there is a hierarchy of vitamins, the best being vitamin A, the next best vitamin B, and so on (Wellin 1953).

Advertising

In this country, something like twenty million pounds a year is spent on advertising foods—more than is spent on any other class of goods. Yet it appears that the result of advertising is far less to make people eat a particular food, than to make them eat brand A rather than brand B of that food. The sales of the different brands of breakfast cereals is in direct proportion to the money spent on advertising them; it is difficult to avoid the conclusion that if firm B were to spend as much as firm A on advertising, their sales would rise until they were equal to that of firm A.

Other Social Factors

Another social determinant is the status of a person or group. Thus, the head of a tribe or of a family may be considered to have a first claim on the more desirable foods. In many cultures this takes the form of the father being given most of the meat or eggs, irrespective of the nutritional needs of the mother or the children.

Finally, the choice of food may sometimes be determined by convenience. Consider a woman in a Western community who lives alone and goes out to work. She may consider it not worth while making herself a cooked breakfast; she may take sandwiches for lunch; for her evening meal it may be too troublesome to cook meat and vegetables, so she opens a tin of beans. Such people, even without undue economic pressure, are often found to be consuming diets which are nutritionally unsound. Scurvy is still most often found in this country in lonely people whose diet is conditioned chiefly by convenience of preparation.

Physiological Factors

Heredity

Experiments with animals have shown that, in conditions in which they show an ability to choose a sound diet, individual animals show this ability in different degrees, and that this ability may be inherited (Dove 1935). Whether man has a similar inheritable ability is quite unknown, but if it exists one might speculate quite interestingly on its effect on man's evolution.

Allergy

A surprisingly large number of people—probably as many as 1 in 20—are allergic to foods, even to such common foods as wheat, eggs, and milk; and allergy to shellfish or strawberries is well known. The identification of the offending food may be easy or difficult, but once identified or even suspected (perhaps wrongly) the pattern of food choice is modified.

Therapeutic Diets

The choice of food is modified by the prescription of a diet for a patient, but the extent of the modification will depend greatly on how closely the patient follows the doctor's instructions. The patient may sometimes be wise in not keeping too rigidly to a prescribed diet; iatrogenic scurvy is not unknown in dyspeptic patients whose diets have been constructed with great rigour but with less nutritional knowledge.

Acceptability

It may or may not be justifiable to call this factor physiological, but I do so because it depends very much upon the individual. I include in it the presentation of food, its palatability, and its possible pharmacological activity. A food of unpleasant appearance, badly served, of the wrong colour, even in an unattractive wrapping when offered for sale, will not be consumed so readily. That is why artificial colours are used in the food industry. That is why you will not get people to eat cakes covered with blue icing as readily as cakes covered with pink icing. That is why the housewife will often add soda to her peas when cooking them, whatever anyone says about it destroying vitamin C.

I need say little about the obvious effects of palatability on food choice. I would, however, point out that, with little or no propaganda, tomatoes and grapefruit have in very recent times become widely accepted foods in this country and that the main factor is undoubtedly their palatability. Similarly, I would refer to the consumption of sugar, which in this country is now some thirty times what it was two hundred years or so ago, and as we have seen depends in different countries on the national wealth. Nutritionally, sugar has the doubtful distinction of being the least desirable food since unlike every other food it contributes nothing whatever except calories to the diet.

Another reason for a food being acceptable is that it has a desirable pharmacological action. It is surely noteworthy that almost every community throughout the world has independently discovered the production of alcohol by fermentation. Similarly, many countries have discovered a plant from which a concoction may be prepared containing the stimulants caffeine or theobromine—tea, mate, coffee, cocoa, and cola.

Nutritional Need

We come finally to the choice of foods for the satisfaction of nutritional need. Whilst exact dietary analyses are rarely available, we may take it that from most varied foods in different parts of the world man often chooses a nutritionally adequate diet, provided he has not been limited by such factors as economic availability. Can we take it then that man and animals have an instinct in food choice which drives them to satisfy their nutritional needs? Let us see what sound evidence exists both for man and for animals, as distinct from unlikely anecdotes.

Some of the best-known experiments in human beings were made by Dr Clara Davis (1928, 1939). Her subjects were infants who were offered at weaning a selection of foods and who ate what foods and in what quantities they chose. Some of them were observed in this way for six years. All of them chose diets which were nutritionally absolutely sound. Now this would appear to prove that infants indeed possess an adequate food instinct. It has also been argued from this that the corollary is also true—that whatever food people do choose to eat must be nutritionally desirable. This is responsible, for example, for the widespread belief that sugar is desirable for children.

Yet there are many examples where man cannot at all be relied upon to make a wise nutritional selection of foods. I have already referred to the Kikuyu, where economic but chiefly social factors determine that they eat a poor diet. Another example is the Indian or Chinese who eats polished rice. How potent is the food instinct which does not teach him to avoid beriberi and imminent death by eating instead unpolished or parboiled rice? Moreover, the experiments of Dr Davis did not tell us what would happen if children were allowed to select from diets which included nutritionally less desirable, or even undesirable, foods instead of only good foods. What would have happened, for example, if sugar and sweet cake and jam had also been offered? Again, the children seemed to have spent some time deciding what foods they preferred; during the first few weeks they tasted most of the foods, but later they settled down to a more restricted diet. This suggests that learning rather than instinct guided their choice—a point to which I shall return.

Having said all this, we cannot overlook the fact that man does frequently and from so many different sources ten hours later Necropsy showed typical lesions in liver and kidneys

Case 2 —In 1942, a primigravida, aged 28, was admitted in a moribund condition after vomiting for 8 weeks She had neuritis, paralysis of the limbs, and pneumonia She died 13 hours later

In the whole of North east Scotland there were 14 maternal deaths due to hyperemesis between 1931 and 1940, 6 of them in residents of Aberdeen and 8 outside the city There has been only 1 such death since (case 2)

The elimination of deaths from hyperemesis is probably the result of improved treatment The records of the fatal cases before the 1939–45 war suggest that many patients with hyperemesis were very toxic when admitted to hospital, and that prolonged, inefficient treatment at home was largely responsible for this (cf the present case 1) Nevertheless, comparison of cases admitted to hospital in 1938–39 with those admitted in 1952–53 showed no difference in distribution by stage of gestation, duration of vomiting before admission, or length of hospital treatment no statistical evidence was found that in 1952–53 patients were sent to hospital sooner by their family doctors, nor did they require shorter treatment in hospital, than in 1938–39 Moreover, that serious forms of the disease still occurred in 1952–53 is shown by the fact that in that year many patients had to have their pregnancies terminated

RELATION OF PARITY TO HYPEREMESIS GRAVIDARUM

Hyperemesis tends to recur in subsequent pregnancies A third to a half of the multigravidæ admitted to hospital with hyperemesis in this series had been treated in hospital for the condition in previous pregnancies Of 106 patients treated for hyperemesis in their second pregnancy, 50 had been treated for this condition in their first Of 82 patients with hyperemesis in their third pregnancy 44 had had it in both, and 11 in 1 of the preceding pregnancies

Of the 159 primigravidæ admitted to hospital, details of subsequent pregnancies are known in 56 cases, of these, 27 were affected in their second pregnancy, and 7 out of 19 had hyperemesis in a third pregnancy

Discussion

It is reasonable to suppose that the relatively low incidence and diminished severity of hyperemesis in Aberdeen and North east Scotland in 1940–48 was experienced in other areas of Britain Robertson (1946) cited Dieckmann as noting that hyperemesis was relatively rare in Germany in the 1914–18 war, and added “ The ætiology of this change in prevalence is complex, but it could be attributed to the different psychosocial environment prevailing in the war years contrasted with the post war years, notably the separation of husband and wife during the years of combat ”

The decrease in the incidence of hyperemesis is most unlikely to be related to food rationing, improvement began abruptly in 1940, before war time food policies had their greatest effect, and after the war the number of cases began to increase before there was any great mitigation of food rationing

Summary

In 1938–39 and in 1949–53 the incidence of hyperemesis gravidarum necessitating admission to hospital was 5–10 per 1000 births in the city of Aberdeen The incidence and the severity of the disease were lower in the war and immediate post war years

Booked hospital patients required less treatment and less time in hospital than patients admitted as emergencies The prognosis for the pregnancy was better in booked cases, and termination of pregnancy was required much less commonly in these than in emergency cases

There were no maternal deaths from hyperemesis gravidarum in North-east Scotland between 1942 and 1953

In many patients, the condition recurred in consecutive pregnancies

I wish to thank Prof Dugald Baird for his advice and criticism

PRIMARY SKIN CANCER OF THE FINGERS SIMULATING CHRONIC INFECTION

H T JOHN
D F C, M B
ASSISTANT, SURGICAL UNIT,
UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

THE soft tissues of the fingers may be the site o *a large variety of tumours, but* malignant disease i somewhat rare When it arises, the true nature of th lesion is *frequently* missed, and diagnosis often depend on whether the possibility is considered at all (Mason 1937) There are many references in published report to the high proportion of false preoperative diagnose (Mason 1929, 1937, Bickel et al 1943, Clarke 1944) and published series often include cases where continued treatment as for a stubborn finger infection, including removal of pieces of nail and curettage of the nail bed, was applied before the diagnosis became obvious

Primary skin cancer of the fingers is usually a squamou cell carcinoma or a malignant melanoma, and basal cell carcinoma is relatively rare

Clarke (1944) found only 18 basal cell tumours on the hand and fingers in a series of 181 cancers of the extremities

Squamous cell carcinoma of the fingers, like carcinoma elsewhere on the hand, may arise in an area previously irritated chemically, by irradiation, or mechanically, or in a previously benign tumour Often, it takes the form of a mass of exuberant granulations, slowly enlarging and involving the surrounding skin and covered with a seropurulent or sanguinous secretion which rapidly becomes malodorous from necrosis or infection with saprophytic organisms The granulations bleed easily and hæmorrhage may be quite brisk Pain is sometimes severe Squamous carcinoma also manifests itself as an ulcer arising on the dorsum or lateral aspects of the digit or on the web between the fingers It resembles in every way the commoner ulcerated cancer of the dorsum of the hand with its rolled or everted edges and granulations in its floor Both types are not infrequently misdiagnosed as chronic infective lesions of the fingers

Melanoma of the fingers may arise in a *long standing* mole, but the subungual tumour commonly arises from *an apparently normal nail bed*, *Hutchinson* (1886) termed this “ melanotic whitlow,” and drew attention to the frequency with which it is confused with a chronic paronychia About 50% of patients with melanoma of the fingers have a history of injury six months or so before the appearance of the tumour In some the trauma is followed by rapid growth or ulceration of a pre existing mole In the nail bed the first sign is often a blue spot or small mass beneath the nail In contrast to the glomus tumour the discoloration is painless and does not disappear on pressure In its later stages a melanoma may be confused with a subungual hæmatoma, but the pigment in a melanoma extends beyond the nail bed and in time the tumour fungates through the nail, destroying it When the melanoma is unpigmented, it closely resembles due to overstimulation, or from an accumulation of metabolic products in the blood-stream. The animal will now stop eating that food and proceed to the next Possibly the eating of another food relieves this unpleasant feeling, or the animal's hunger may simply not yet be satisfied and it has learned that the eating of another sort of food will stay its hunger yet not increase its discomfort

Whatever the reason the animal will in this way choose a variety of foods from which it will eat its fill We must remember that by so doing it will, even from a fairly restricted choice of foods, obtain a wide variety of nutrients, for almost all foods contain several nutrients Should it by chance avoid some foods and so develop deficiency of one or more nutrients, it might be able to learn to eat them if the deficiency is of a nutrient whose consumption results in rapid improvement

We must add, too that the animal's experiences may not have to be repeated in their entirety by its offspring, especially if it is a human animal He will be able, in varying degrees to direct his progeny to nutritionally sound food selection by education

Whilst this brief discussion may not provide an entirely satisfactory explanation of the complex problem of food selection and food instinct, it will I hope provide a basis for a more complete understanding of the problem than has been possible hitherto However little ultimate value these speculations have, they will at least have done a useful service if they only delimit the area of determinants of food choice within which instinct may play its part. Remember the infant and the boot-polish

SPECIAL UNIT FOR JUVENILE RHEUMATISM, CANADIAN RED CROSS MEMORIAL HOSPITAL TAPLOW, BUCKS

IMMUNOLOGICAL studies have established beyond reasonable doubt that most patients with acute rheumatic fever show evidence of recent infection with β-hæmolytic streptococci of Lancefield's group A The serological findings, summarised by McCarty (1952), include the repeated observation (Anderson et al 1948, Rantz et al 1948, Harris and Harris 1950) that patients in whom rheumatic fever develops after streptococcal infection show a significantly greater antibody response than do patients with uncomplicated infections This seems to hold not only for antistreptolysin O (A.S O) but also for antibodies to streptococcal hyaluronidase, streptokinase, and possibly other streptococcal antigens

Rantz et al (1951) also studied respiratory infections with group-A hæmolytic streptococci and the associated A S O response in infants and young children They found three patterns of antibody response roughly related to age (1) a feeble response in infants, (2) a vigorous but short-lived response in young children (mean age 36 7 months), and (3) a vigorous and sustained response in older children (mean age 57 9 months) They described evidence that this sequence of antibody-response patterns, although related to increasing age, was more closely related to *repeated* streptococcal infections and they attributed the enhanced response to conditioning of the antibody-forming organs by repeated exposure to streptococcal antigens Rantz et al (1951) have linked this conclusion with the finding, mentioned above that in rheumatic fever antibody response is further enhanced. and have suggested that these observations, together with the known rarity of rheumatic fever in very young children, support the idea that " sensitisation " to streptococci or their products is closely related to the pathogenesis of rheumatic fever If this concept were correct, the incidence of raised A S O titres in children with acute rheumatic fever should be independent of the age of onset We describe here a survey of A S O levels in rheumatic children aged 3–12 years

Material and Methods

We have surveyed all eligible cases of acute rheumatic fever with onset before the 12th birthday admitted to this hospital in the seven-year period from April, 1948 Cases were taken to be eligible only if they fulfilled the diagnostic criteria of Jones (1944) (excluding chorea as a significant feature) and were seen in their first rheumatic attack within four weeks of onset of symptoms The survey was directed particularly at the relation of age to the frequency of raised A S O titres, the geometric mean of the A S O levels the frequency of preceding upper-respiratory-tract infections (within a month of onset), and the frequency with which group-A β-hæmolytic streptococci were recovered from the patients

Throat and nose swabs were taken from each patient on admission and after one week and were plated respectively on horse-blood agar and on the same medium containing gentian-violet (1/500 000) Hæmolytic streptococci recovered were tested for group-A-specific polysaccharide by Lancefield's (1933) method

Venous blood samples were taken on admission and at weekly intervals for serum-A.S O estimations The highest titre found within four weeks of admission was recorded for this survey Antistreptolysin was estimated by a method (Johnson 1955) based on Hodge and Swift's (1933) modification of Todd's test This serological method was standardised with Todd's horse antiserum as a reference and gave consistent results throughout the seven years of the study except for the period October, 1952, to July, 1953 when the standard globulin solution underwent gradual and, at first, unnoticed deterioration When this was discovered a new standard globulin preparation was obtained and cases admitted during this nine month period have been excluded from the survey Were they included, the outcome of the analysis would not be materially affected Excluding this period, the mean A.S O levels did not vary significantly from year to year, either in the group included in this study or in all A S O estimations carried out in the laboratory We have taken the arbitrary value of 200 units or more per ml to indicate significant antibody response to streptococcal infection.

Results

The criteria for selection were fulfilled by 121 cases, of which 14 were excluded because they fell in the unreliable serological period. Of the 107 remaining cases, 55 were in boys and 52 in girls At each age the distribution between the sexes was approximately equal finger persists despite treatment and in the absence of an adequate local or general cause, such as retained dead nail or foreign body, osteitis, or vascular disease, biopsy must be done Any apparent chronic granulomatous lesion with bluish pigmentation must be viewed with suspicion until proved innocent Benign lesions of the nail bed, such as subungual fibroma, subungual exostosis, or glomus tumour, do not break through the nail, nor do they invade the skin The malignant lesions at this site, however, they begin, lift the skin and nail and eventually replace them with fungating tumour (Jaffe 1930)

Biopsy of the tumour is easy under ring block anæsthesia and can be carried out in the outpatient department If it does not at first show the true nature of the tumour, repeated biopsy of the finger or biopsy of glands will establish the diagnosis

Summary

Primary cancer of the fingers is uncommon and squamous cell carcinoma and malignant melanoma are the commonest forms

These neoplasms are often confused with septic lesions of the fingers 5 examples of this confusion of diagnosis are described

Any apparent chronic infection of the fingers which does not respond to treatment should be investigated by biopsy

I should like to thank Prof R S Pilcher for his help and encouragement in preparing this paper, Mrs Gwen Hilton for permission to report case 5, and Mr A Bligh for the photograph

THE secretions of the anterior lobe of the pituitary gland and the adrenal cortex are known to influence gastric secretion When these glands are atrophied, as in Simmonds's disease (Escamilla and Lisser 1942) and Addison's disease (Rowntree and Snell 1931, Sorkin 1949), gastric secretion is depressed and treatment with cortisone may restore it (Stempien and Dagradi 1954, Kyle 1955) Conversely, the administration of corticotrophin or of cortisone increases the acidity of the gastric juice (Gray et al 1951) and the excretion of uropepsinogen (Gray et al 1954) and may aggravate or even cause peptic (especially duodenal) ulceration (Sandweiss 1954) Hydrocortisone increases the excretion of uropepsinogen, but corticosterone does not (Wolfson and Timmis 1955) In Cushing's syndrome, in which adrenocortical hormones are produced in excess, the gastric secretion might be expected to be increased, but few observations have been reported, the excretion of uropepsinogen may be increased (Gray et al 1952) and gastro-intestinal hæmorrhage may develop (Swan and Stephenson 1955, Knowlton 1953) In the adrenogenital syndrome the gastric juice is said to be normal (Broster 1934)

It is not clear, however, whether the pituitary and adrenal hormones influence gastric secretion in the absence of overt disease of endocrine glands Some patients with peptic ulcer have diminished pituitary and adrenal activity, judged by negative Thorn tests (Turner 1951, Fota 1954), and in some patients with duodenal ulcer the urinary excretion of formaldehydogenic steroids has been decreased during exacerbations and largely restored during remissions The excretion of 17 ketosteroids is normal (Sandweiss et al 1950)

The present investigation was undertaken to measure gastric secretion in patients with Cushing's syndrome before and after treatment by subtotal adrenalectomy, and to discover whether, in these or in other people, there was any correlation between the level of gastric secretion and the urinary excretion of adrenal cortical steroids

Material and Methods

Gastric secretion in Cushing's syndrome was studied in 11 patients, 8 before and 7 after surgical therapy The operation in 6 was subtotal adrenalectomy (removal of $^9/_{10}$ of one gland and all of the other) and in 1 (case 9) subtotal removal of one gland which contained a cortical adenoma A satisfactory remission was obtained in all

The urinary excretion of reducing corticoids was measured in 5 patients with hyperchlorhydria (more than 45 clinical units of free acid in a gruel fractional test meal) but without clinical evidence of endocrine disorder

The excretion of 17 hydroxycorticoids was measured in the 8 patients with Cushing's syndrome and in 8 healthy people with normal gastric secretion, 8 patients with duodenal ulcer, 5 patients with hyperchlorhydria but no peptic ulcer, and 5 patients with achlorhydria without other evidence of disease

Gruel fractional test meals lasting two and a half hours were studied in each person This method of gastric analysis has serious limitations but was the one most readily available Histamine was not given, because we thought it might be harmful to patients with adrenal disease In those with Cushing's syndrome the test was done shortly before adrenalectomy and some months after operation, when cortisone replacement had been

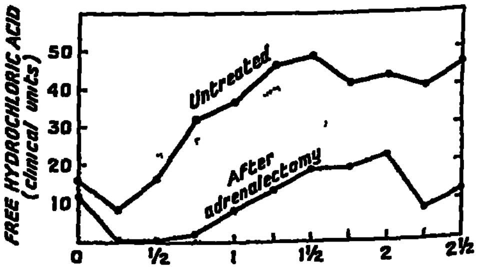

Fig 1—Free hydrochloric acid after fractional test meals in Cushing's syndrome (Figures derived from data in table I Normal range is derived from Bennett and Ryle (1921))

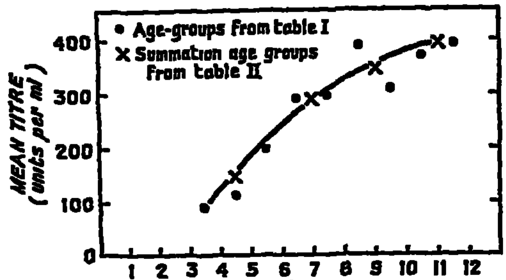

Fig 3—Age and mean A.S O titre.

localised indolent streptococcal infections of infants are gradually replaced (by about the age of 5) by a more acute, and clinically well defined, pharyngitis This altered response, they suggest, is related to sensitisation to streptococci through repeated infections Rantz et al (1951) have shown that such repeated streptococcal infections in young children lead to a striking enhancement of the antibody response their findings therefore support the idea that sensitisation (i e, increased antibody response) to streptococci tends to develop in childhood It is known that repeated infections with group-A hæmolytic streptococci commonly precede attacks and recurrences of rheumatic fever and this, together with the well established increase in antibody response which most rheumatic subjects show, has supported the concept that rheumatic fever itself is a phenomenon of sensitisation The results reported here suggest, on the contrary, that in young children with acute rheumatism this state of sensitisation is not uncommonly poorly developed and should therefore probably be regarded as dissociated from the mechanism by which streptococci induce rheumatic fever

Summary

107 children with acute rheumatic fever, aged 3–12 years, showed no age differences in the frequency of preceding upper respiratory-tract infection or of positive throat or nose swabs for group A β hæmolytic streptococci

20 children included in this study were under the age of 6 years, these showed a significantly lower frequency of raised antistreptolysin-O titres, and a significantly lower mean titre, than those over 6 years of age

This result suggests that, contrary to the current concept, the pathogenesis of rheumatic fever is not primarily related to the sensitisation to streptococci or their products that commonly occurs in childhood

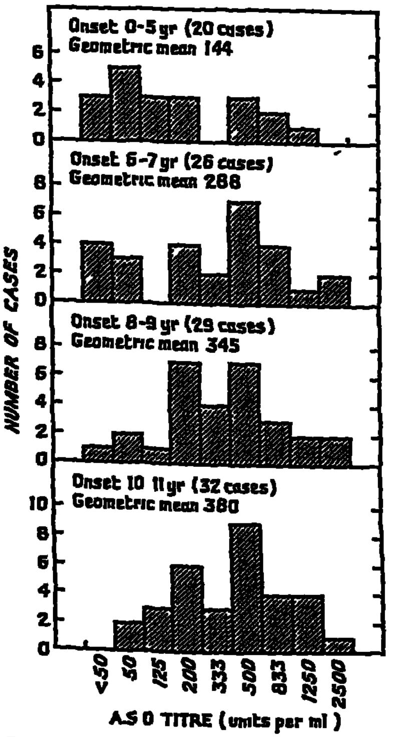

Fig 4—Distribution of actual A.S O titres in the four age-groups

The standard globulin preparation obtained in July, 1953, was kindly sent by Dr B F Massell, the House of the Good Samaritan, Boston, Mass, U S A

PALLIATIVE HORMONE THERAPY OF ADVANCED MAMMARY CANCER

REVIEW OF 106 PATIENTS STUDIED IN SEVEN YEARS

G L Foss
O B.E, V R D, M.A, M D Camb
CLINICAL ASSISTANT TO THE ENDOCRINE CLINICS,
UNITED BRISTOL HOSPITALS

It has long been known that the ovaries influence the growth of the breasts, and that oophorectomy sometimes causes breast cancer to regress (Schinzinger 1889, Beatson 1896, Boyd 1900, Morris 1902, Thompson 1902, Lett 1905a and b)

Haddow (1935) found that certain carcinogenic hydrocarbons retarded experimental malignant growths in laboratory animals, and some of these substances had an œstrogenic effect This discovery led to a trial of synthetic œstrogens for carcinoma of the breast Most workers agreed on the value of œstrogens in postmenopausal women and that the best responses were obtained in soft-tissue metastases, with little benefit in skeletal metastases

Androgens were given to patients with breast cancer to inhibit œstrogens which might be stimulating the growth (Loeser 1938, 1939, 1940, McWhirter et al 1944, Adair and Herrmann 1946, Herrmann and Adair 1946, Cutler and Schlemenson 1948, Prudente 1948, Lowenhaupt and Steinbach 1949, Douglas 1952, Hallberg et al 1953)

It is now considered that some breast cancers are dependent on œstrogens, whose removal will improve the prognosis This view is emphasised by Cade (1955) and Dodds (1955)

The insufficiency of oophorectomy and/or androgen therapy gradually became evident Œstrogens secreted by the adrenal cortex are increased after oophorectomy because the adrenal glands then hypertrophy With the advent of cortisone to control patients during and after operation it was logical to remove the adrenal glands Since Huggins and Dao (1952) and Huggins and Bergenstal (1952) reported a series of cases so treated, adrenalectomy and oophorectomy have been widely practised for the young patient with advanced metastases If extirpation is complete, only those cases which presumably depend on œstrogens show a rapid and dramatic improvement and a recession of tumour growth which may last several months

All workers are agreed that there is no means of determining which case depends on œstrogens, and can then be expected to improve under treatment, except trial of hormone therapy This takes several weeks, but there is a dramatic response one *to six days* after adrenalectomy if the tumour is œstrogen-dependent

Old postmenopausal patients often show a spectacular temporary remission, particularly of soft tissue lesions, after large doses of œstrogens—possibly owing to a is evidence that some other adrenocortical hormones, besides the 17-hydroxycorticoids, may influence the gastric secretion In Cushing's syndrome, for instance, we have found the excretion of reducing corticoids to be increased more consistently than that of 17 hydroxycorticoids (D A D Montgomery and R B Welbourn, unpublished), and the patient (fig 2) who had 70 units of free acid and no 17-hydroxycorticoid in the urine excreted large amounts of reducing corticoids (8 2 mg in 24 hours) Of the 10 hyperchlorhydric patients who did not have Cushing's syndrome (fig 2) only 4 excreted more 17-hydroxycorticoids than normal On the other hand, 4 of 5 hyperchlorhydric patients (table II) excreted more reducing corticoids than normal This difference, though not significant, is suggestive

Our conclusions appear to conflict with those of others who found diminished pituitary and adrenocortical activity in patients with peptic ulcer Foti's (1954) series, however, included only patients with gastric ulcer, a condition in which gastric secretion tends to be diminished In Turner's (1951) series, in which the site of ulceration was not stated, it was suggested that the patients were studied during a phase of adrenocortical exhaustion following a period of overactivity which had induced an exacerbation of ulcer symptoms There seems no way of reconciling our results with those of Sandweiss et al (1950), who found diminished excretion of formaldehydogenic steroids in patients with duodenal ulcer

Gastric secretion is influenced by many factors, including vagal and gastrin stimulation, enterogastrone inhibition, and the number of parietal cells in the stomach It is not surprising, therefore, that no general correlation has been found between adrenocortical activity and gastric secretion Further investigation of their relationship is required by more precise methods of estimating adrenal and gastric function

Summary

Gastric secretion, measured by the gruel fractional test meal technique, is often increased in Cushing's syndrome and is restored to normal by adrenalectomy

The excretion of reducing corticoids is often high in hyperchlorhydric people who have no other signs of disease of the endocrine system

A high excretion of 17-hydroxycorticoids is usually accompanied by hyperchlorhydria

Adrenocortical hormones probably play a part normally in influencing gastric secretion

We wish to thank Prof H W Rodgers for his interest and help in this investigation

PARAPLEGIA FOLLOWING SPINAL ANÆSTHESIA

J P Payne
M B Edin, F F A R C S, D A
LECTURER IN ANÆSTHESIA, POSTGRADUATE MEDICAL SCHOOL OF LONDON, CONSULTANT ANÆSTHETIST, HAMMERSMITH HOSPITAL, LONDON

S-E Bergentz
Med lic
ASSISTANT SURGEON, CENTRAL HOSPITAL, FALUN, SWEDEN

Many conflicting views have been expressed concerning the ætiology of paraplegia following spinal anæsthesia for, although in many cases the paralysis has been associated with adhesive arachnoiditis, the exact cause of the lesion has been difficult to determine There is, however, evidence suggesting that under certain conditions the anæsthetic itself may be incriminated The case reported here supports this view

Case-report

A housewife, aged 45, was admitted to hospital on Feb 24 1955, unable to walk She had difficulty with micturition, and her bowels were constipated In the autumn of 1953, a myoma of the uterus was removed under general anæsthesia, and a year later she was readmitted to hospital with symptoms and signs of small bowel obstruction Laparotomy was done under spinal anæsthesia and the obstruction was relieved The anæsthetic was given by the surgeon with the patient in the lateral position The spinal needle and syringes were autoclaved, and the skin was prepared with a 70% solution of ethyl alcohol 20 ml of a 1/500 " light " solution of cinchocaine hydrochloride ('Nupercaine') was used, and before the neck of the ampoule was opened it was sterilised with 70% ethyl alcohol, at no time was it immersed in antiseptic The postoperative course was uneventful until the seventh day, when the patient complained of slight weakness in her right leg Apparently little attention was paid to this complaint and she was discharged a few days later During the following weeks the weakness in her leg became more pronounced, and by the beginning of December, 1954, she was unable to walk unaided In January, 1955, there was progressive deterioration, with spread of the weakness to her left leg For three weeks before her admission to hospital she had been completely unable to walk, her bladder control had become more difficult, and constipation increasingly troublesome

Neurological examination on admission revealed absence of abdominal reflexes but very brisk knee and ankle jerks in both legs, with clonus, bilateral extensor plantar responses were elicited From the level of the 6th thoracic segment downwards sensibility to light touch, pinprick, and temperature, was impaired on both sides, position sense was absent There was muscle weakness in the abdominal wall, and wasting was obvious in both lower limbs

Cisternal puncture and diagnosis—Repeated attempts at lumbar puncture were unsuccessful and eventually cisternal puncture was done 45 ml of cerebrospinal fluid (C S F) was removed and was replaced by 100 ml of air There was a block at the level of the 4th thoracic vertebra Spinal tumour was provisionally diagnosed

Operation and postoperative course—On the basis of this diagnosis Dr Stig Lindgren did a laminectomy When the dura was exposed no pulsation was noted, and when it was opened extensive adhesions between the meninges and the spinal cord were found and divided As the ventral aspect of the cord was approached a cystic swelling extending upward at the level of the 6th thoracic vertebra was seen compressing the cord From this swelling 50 ml of clear colourless fluid was aspirated, and it was decided that the cyst was continuous with the subarachnoid space above After operation the patient's condition improved for two weeks, but this improvement was not maintained and her condition is now the same as before operation

Histological examination confirmed the operation finding of adhesive arachnoiditis There was no evidence to support the earlier diagnosis of spinal tumour erum-calcium level was investigated on many occasions ut was never found significantly raised

Side-effects

Œstrogens

Postmenopausal bleeding was not uncommon in patients taking a small ineffective dosage of 0 3–1 0 mg q i d for a month or so, treatment had then been stopped by either the patient or the doctor The correct procedure is to increase the dosage to 5 mg q i d and to impress on the patient the importance of not interrupting regular therapy With 5 mg q i d interval bleeding takes place only rarely, and then perhaps after the tablets have been omitted for a day, if patients were given continuous therapy with 20 mg q i d or more for many months, there was no bleeding Withdrawal of œstrogen caused bleeding in 31 2% of 61 menopausal cases 10 of them bled on a dosage of stilbœstrol from 0 3 mg q i d to 5 mg q i d, and 9 on one of 5 0 mg q i d, of the 42 remaining patients 2 on 0 3 mg q i d had not bled in seven and eleven weeks before death, and no report was available for 1 patient who discontinued attendance In 30 patients who received 5 0–50 mg q i d there was no bleeding during their treated lifetime—sometimes for as long as 125 weeks There was no bleeding in 3 patients while having ethinyl œstradiol 0 05 mg q i d or more, in 1 patient while having œstradiol benzoate 10 mg on alternate days, and in 5 patients while having stilbœstrol 1–5 mg q i d in addition to a daily dose of 100–300 mg of testosterone propionate by injection

Pigmentation was striking in some patients, particularly the older group and in those who were normally darkly pigmented, and in this series it developed in 32 8% It was very intense around the nipples and areolæ, the linea nigra, and the perineum, and in senile keratoses The colour varied from dark brown to almost black The nipple of an irradiated breast was often less pigmented than that of the other breast After months of therapy the pigmentation often disappeared, even though big doses were continued In association with this there was sometimes sufficient keratinisation of the nipples to give them a greyish black tinge which, like the pigmentation, ultimately disappeared, leaving a paler smooth nipple

Œdema of the ankles and lower legs was not unusual with continued large dosage, and sometimes the œdematous arm on the side of the radical mastectomy was still further enlarged Rarely in some of these old patients congestive failure was precipitated, but it was usually only necessary to restrict the intake of salt and to give an oral diuretic—e g, 'Mercloran' and acetazolamide

Androgens

Side effects with androgens naturally depend on the duration of treatment and the dosage, but there was also an individual susceptibility The most powerful known action of androgens is anabolic, with retention of nitrogen and sodium, increasing the weight of many patients, and making their muscles noticeably larger and firmer though the patients had advanced cancer Much of the benefit of androgen therapy is probably due to this effect, with subjective improvement of appetite and sometimes an increase in well being and energy, enabling patients to continue their work or their domestic duties There was often pronounced plethora

The unpleasant side effects are those of virilisation This varied from one patient to another some were rapidly affected, whereas others, who survived only a short time, showed very little virilisation The distribution of signs of virilisation, expressed as a percentage of patients treated with androgens, was as follows

Sign of virilisation	*No of patients*
Hirsutism	33 (*58 0%*)
Voice change	26 (*45 5%*)
Enlarged clitoris	15 (*26 3%*)
Acne	11 (*19 3%*)

Hirsutism was the most embarrassing and unpleasant side-effect for the patient and was often very considerable Not only was there an intense growth of long coarse hair on the cheeks, upper lip, chin, and general beard area but also the excess hair on the body, arms, and legs was considerable It is the former, however, to which the patient naturally objects Patients developing hypertrichosis were all recommended to shave daily, preferably with an electric razor, and not to resort to depilatory agents such as wax, pumice, emery paper, electrolysis, and plucking, all of which methods tend to cause infection of the skin follicles and unsightliness noticed by all, whereas, with a well kept shaven face, the fact that the patient shaves is known only to herself and her husband One patient with particularly heavy hirsuties controlled her appearance extremely well by rubbing off the hair from time to time with the pith side of lemon peel

Voice changes probably depend on the normal pitch of the patient's voice They developed early in some and very late in others The voice may be very deep and gruff or husky, or may crack and change like that of a pubescent boy Patients sometimes commented on their inability to sing in the same register, which may drop an octave or so This was rarely a source of dismay but is irreversible

Enlargement of the clitoris was sometimes considerable although not invariable The glans was often enlarged to 0 8–1 0 cm in diameter, appeared congested, and protruded from the enlarged prepuce, whose sulcus contained smegma The body of the clitoris was often 2–3 cm long Concomitant with this overgrowth of the clitoris there was increased vaginal secretion

Acne developed only occasionally The skin was more greasy in most of the patients in whom acne developed, and the acne then usually affected the face, chin, back, chest, and shoulders and probably depended partly on personal cleanliness

All the above mentioned virilising side effects were seen with all the androgens used, occurring almost as much with methyl androstenediol as with testosterone and its esters Although methyl androstenediol is said to be not so virilising, it certainly was so in the dosage of 100 mg daily for a long time

Increase of libido was an important side effect (cf Foss 1951), 14 patients (24 6%) admitted to a considerable increase of libido, but the actual incidence was probably higher It may be associated with hypertrophy of the clitoris Patients commented on constant irritability and sensitivity, but in some cases where examination revealed an enlarged clitoris an increase in libido was denied

Results

Survival—55 5% of the 106 patients were still alive 6 months after starting hormone treatment, 31 2% after 1 year, 11 6% after 2 years, 4 7% after 3 years and after 4 years, and 0 94% after 5 years The average age of these 106 women at the beginning of therapy was 55 years and the mean survival for the group 48 weeks The mean number of weeks lived in 5 years was 18 6% of the expected survival (Foss 1955) After the percentage expectancy of life in 5 years had been calculated for each case, statistical analysis gave the following results

Group	*Age (yr)*	*No of patients*	*% expectancy*	*S D*
1	40 or less	9	9 42	±3 6
2	41–60	61	16 3	±2 1
3	61 or more	36	24 5	±4 45

The differences between groups 1 and 2, and between groups 2 and 3 were not significant, but between groups 1 and 3 the expectancy of life was so increased as to be outside the range of random chance If the survival figures from the onset of symptoms are used instead of from the start of hormone treatment, we find that the average age at onset of symptoms was 51 2 (range 26–76), and the average survival 58 5 months (range 10 months–27 years Dividing the patients into age groups we get

Group	*Age (yr)*	*No of patients*	*Average age at onset (yr)*	*Survival (wk)*	*5 yr % expected survival*
1	Up to 40	18	35 5	230	88 8%
2	41–60	66	50 5	255	98 8%
3	61+	22	66 5	173	68 6%

was a gradually constricting arachnoiditis with subsequent interference with the blood supply to the cord

Williams (1954) described 9 cases in which adhesive arachnoiditis developed after spinal anæsthesia He drew attention to Horsley's observation (Horsley 1909) that the pathological changes in the cord and membranes in adhesive arachnoiditis were found most commonly in the mid dorsal region According to Williams there is a tendency for the anæsthetic solution to accumulate in this area (which in itself increases the risk of arachnoiditis) and he pointed out that the spinal cord is particularly vulnerable to injury in the region of the 6th dorsal vertebra because of a relatively poor blood-supply

Other anæsthetic techniques—Damage to the spinal cord and membranes may be caused by other anæsthetic techniques Koch (1947) described paraplegia in a patient who was inadvertently given an intrathecal injection of 5 ml of an 80% solution of ethyl alcohol, and Rosenbaum et al (1952) reported a series of 6 cases in which arachnoiditis developed after "heavy" cinchocaine had been used to induce "saddle" block anæsthesia in childbirth They suggested that the circulation through the vertebral vascular system is impaired by the high abdominal pressure during labour, and as a result a high concentration of anæsthetic solution may persist in the subarachnoid space longer than normal

pH of anæsthetic solution—One further factor to be considered in the causation of adhesive arachnoiditis is the hydrogen-ion concentration of the anæsthetic solution Normally the C S F is slightly alkaline, with a pH in the region of 7 6 The pH of anæsthetic solutions of cinchocaine is definitely acid (4 5 or less) Although a small volume of injected acid solution is probably neutralised at once, it seems likely that when larger volumes are injected neutralisation may be delayed and the membranes and spinal cord in contact with the solution damaged

Although much work remains to be done on adhesive arachnoiditis, there is sufficient evidence to justify abandoning techniques that require large volumes or continuous injection of anæsthetic solution Permanent paraplegia with its profound social and economic repercussions is too great a price to pay for any temporary advantage gained by the surgeon

Summary

A case of adhesive arachnoiditis following spinal anæsthesia with "light" cinchocaine is described

The ætiology of adhesive arachnoiditis, with particular reference to contamination and infection of the C S F, and anæsthetic drugs and techniques, is discussed

The use of "light" cinchocaine and continuous spinal anæsthesia should be abandoned

We are indebted to Dr Stig Lindgren and Prof Ian Aird for their advice and criticism

DIAGNOSIS OF ISLET-CELL TUMOURS OF THE PANCREAS

J D C KELLY

M R C S

LATE HOUSE PHYSICIAN, ST JAMES' HOSPITAL, LONDON

ISLET-CELL tumours of the pancreas have been known since Nicholls (1902) described them, but neither their physiology nor their clinical features were understood until after the discovery of insulin by Banting and Best in 1922 An islet-cell tumour was first successfully removed by Roscoe Graham (Howland et al 1929)

Despite the supposed rarity of this condition its prompt diagnosis is of great importance because these patients have often been labelled as neurotics, psychotics, or epileptics and have been treated as such

Until quite recently the diagnosis depended entirely on the fulfilment of the triad of criteria of Whipple and Frantz (1935) (1) a hypoglycæmic attack resulting from fasting or exertion, (2) a blood-sugar level below 50 mg per 100 ml during the attack, and (3) the prompt relief of an attack by glucose

Assay of serum for insulin content offers a possibility for differentiating hyperinsulinism from functional hypoglycæmia Willebrands and Groen (1954) obtained higher values than normal in 4 patients with an islet-cell adenoma confirmed by operation After removal of the tumour the insulin content of the serum returned to a normal level
